not many applications have been made of it, notwithstanding the services that a machine of this kind is capable of rendering in barracks, lyceums, hotels, &c. M. Andoye, an inventor, has recently taken up the question again, and has proposed to the Société d'Encouragement a model that gives a practical solution of it. The use of this will allow a notable saving in time and trouble to be effected. This brush (see engraving) revolves on a horizontal axle, supported by a cast-iron frame similar to that of a sewing machine. Motion is communicated to it by a double pedal, which actuates a connecting rod and a system of pulleys. The external surface of the brush contains three channels, in which the foot gear to be polished is successively placed. In the first of these the dust and mud are removed, in the second the blacking is spread on, and in the third the final polish is obtained. In order to guide the blacking to that part of the brush which is to receive it, M. Andoye protects the lower part of the latter by a half-cylinder of sheet iron. On this there is placed a vessel containing the blacking, and into which dips a copper cylinder having a grooved surface. The horizontal axis of this cylinder is movable. When at rest it is so placed that the cylinder is an inch or so below the brush; but when the operator pulls a button that is within reach of his left hand, the axis is lifted, a contact takes place between the brush and the cylinder, and the former is thus given a rotary motion. As the cylinder still continues to dip into the blacking, the latter is thus spread over the brush.—ESSAR.

[56142.]—**Wheatstone's Bridge.**—The querist is quite right; it is an expensive matter to have three sets of resistance coils, and of course if it is for outdoor work, they are really necessary. But for indoor or experimental work they are not; although you must have one or a set to begin with, to make the others by; the same set would be used afterwards to balance the resistance to be measured. I have frequently used uncoppered carbon rods as resistances, same as now cheaply sold for arc lighting. Fix a clamp on one end, and move the other clamp along until the desired resistance is obtained, or if several clamps are fixed on at different distances from the end one, many resistances can be introduced as needed, by merely securing the wire by the binding screw. I have heard that the resistance of carbon varies after the passage of a current through it; but I have never noticed this variation myself. Perhaps it requires a very delicate galvanometer to detect it. If the querist cannot afford German-silver cotton-covered wire, he should get some copper cotton-covered of various sizes, winding reels in different directions; that is to say, one 5ohm left-handed, and the other 5ohm right; when these are joined together as 10ohms, no induction would take place, being differently wound. When not wanted for resistances they could be used for magnets, and a variety of purposes. If he cannot get covered wire he should get several glass tubes varying in length and about $\frac{1}{2}$in. internal diameter. To the one end of each tube fit a cork, first passing through it a copper wire, then fill with water, and put a cork in the other end; before pushing it in, make a hole through the cork so that a stout copper or brass wire will slide tightly through it. When this tube is put in circuit with a battery and galvanometer, moving the wire in or out varies the deflection of the needle, showing the resistance is increased or otherwise; in fact, these tubes are made exactly like the water-regulator to a medical coil. These water resistances I do not think would do for measuring high resistances, because such a number of cells would be used as to cause gas to be given off at the electrodes. In such cases (I think "Sigma" says), turpentine or alcohol have to be substituted. I shall be pleased to give further information, or to answer any question concerning the above.—A.S.T.E. AND M.S.E.

[56165.]—**Weevils.**—Try carbolic acid: it entirely destroyed some insects which appeared in a table of mine some time since.—ASA.

[56170.]—**Microscopical.**—The reply of "B.Sc. Plymouth," to H. T. Barnett is, I fear, but little calculated to give him that sound practical advice which he desires. "B.Sc." surely ought to know, and had he had practical experience would have known, that the people who "make condensers, test plates, and diatoms their hobby," are the very people who do *not* go in for binoculars, for the simple reason that in nine out of every ten cases they are of no earthly use to them, working, as they almost exclusively do, with high powers which are not suitable for use with the binocular at all, at least not with the usual Wenham form; and the same remark holds good with histologists and the class of men like Pasteur and others mentioned by "B.Sc.," whose work lies almost entirely with high powers. If H. T. B. intends to confine himself to either of these lines of study, then, no doubt, a monocular is the stand for him; but if he desires to study with his microscope in a more general way the beauties of natural history—such, for example, as the foraminiferæ, which subject Dr. Carpenter has made so much his own, the eggs of insects, the pollens, the lichens, the ferns, the mosses, and the thousand other objects requiring chiefly low or medium powers (and much useful work has been done with such powers), then, like Dr. Carpenter, he will find the binocular a comfort, a pleasure, and a help. H. T. B. would do well to keep before him the fact that, possessed of a binocular, he can in a moment convert it into a monocular by an adjustment of the prism, and will so be enabled to follow the whole range of microscopic observations, using his instrument as either a binocular or monocular, as may be best suited to the particular object he wishes to examine. One piece of advice, however, which "B.Sc." offers, I highly commend —viz., study Carpenter and Beale on the subject. In the last edition of the former author's book, he will find, at page 81, the following: "The value of stereoscopic binocular vision in scientific investigations being now admitted by all who have really worked with it upon suitable objects, the author would earnestly recommend everyone about to provide himself with even a second-class microscope, to incur the small expense of the binocular addition." This expense, from a catalogue of Crouch's student's binocular now before me, amounts to just 40s. over the monocular form of the same instrument, and I may say from long experience, that after he has once adjusted his instrument to the width of his eyes, it is not only not troublesome to use, but is much more comfortable in use, by an avoidance of the strain upon the left eye whilst looking down the right tube with only one eye. In the earlier chapters of Carpenter on the microscope, he will find the question of binocular vision discussed in a calm and scientific manner, and with an entire avoidance of that most undesirable practice of sneering at one class of observers because forsooth they do not happen to follow the particular line most favoured by another class. Let such sneerers remember that the honoured president of the Royal Microscopical Society, Dr. Dallinger, was, and is, one of the school who make condensers, test slides, and diatoms their hobby, and that to the patience and manipulative skill acquired in that school is largely due the wonderful discoveries he has made in a field of inquiry lying on the very boundary line of life, and also that the requirements of that school have largely contributed to the marvellous improvements in our modern object-glasses.—W. P. OLDHAM.

[56170.]—**Microscopical.**—"B.Sc., Plymouth," divides microscopists into two classes, the brass and glass school, and those who use the instrument as a means to an end; and he defines that end as "knowledge with a view to benefiting the human race," which is, to say the least of it, a philanthropic view of the aims of the gentlemen he names. But let that pass. I venture to state there is another class much larger than either or both of the others, who also use the microscope as a means to an end, and that end is the pleasure derived from the acquisition of knowledge. To this class belong the great army of all-round microscopists—those who delight in investigating the secrets of nature, not in one direction only, but in many directions, and not with any direct expectation of benefiting mankind by their studies, but with the (I must admit) inferior aim of deriving pleasure and instruction for themselves. To this class I maintain that a binocular microscope is of as much importance as a pair of spectacles with two glasses instead of only one is to a person whose sight is failing. The latter can read with one glass perfectly well, but certainly not with anything like the same degree of comfort or pleasure. So with the monocular microscope. You can see objects perfectly well with it, and when using high powers must perforce convert your binocular into a monocular for the time; but when examining larger objects, such as insects and botanical objects, I maintain that the use of the binocular gives a far juster conception of the object as it is than the monocular. In fact, there is exactly the same difference between the two as there is between viewing a large object, such as a house or a table, and a perfectly accurate picture of the house or table. I know I am only going over old ground, threshing matters pretty well threshed out; but I see no reason why we all-round microscopists should not enjoy our binoculars in peace, leaving to those whose delight is in the resolution of a diatom marking, or the discovery of the flagella on a microbe, the pleasure of using monoculars only, if so disposed. Neither do I think we are worthy of the sneers often implied—I do not say by "B.Sc.,"—because we have neither the desire, nor, if we had the talent, the means, to pursue with success special investigations.—A BINOCULAR M.D.

[56170.]—**Monocular v. Binocular.**—It seems to me that "R. D. R." and "B.Sc., Plymouth," are mistaken in thinking there can be two opinions about this matter. Each is best in its own department. The question is similar to a horological one of chronometer and lever escapement. The lever is by far more suitable for the pocket; but no one would think of fitting it in a ship's watch. Wenham's binocular is more suitable than the monocular for low powers up to 1in. or $\frac{2}{3}$; but no one would think of examining the cholera bacillus with it. I do not say there is no loss of definition with the binocular; but I do say that such loss is quite inappreciable in that class of objects which is suitable for a binocular, and for which the stereoscopic effect is of paramount importance. I confess that I "make microscopes, condensers, test plates, and diatoms my hobby," but I should as soon think of carrying a regulator on my back, instead of a watch in my pocket, to tell the time by, as of investigating the surface-markings on diatoms with a binocular. With regard to "R. D. R.'s" last paragraph, I should think that the excellent work achieved by the Rev. Dr. Dallinger, F.R.S., is in some measure at least due to his having devoted himself in no small degree to the diatom and test object work. Several letters have appeared in these columns advocating the use of short tubes à la Continental model. In the first place, an object-glass corrected for a long tube will not perform correctly in a short tube, and vice versâ. Secondly, in order to maintain the same magnification with a short tube as with a long one, a deeper eyepiece must be used—e.g., it takes Zeiss's Nos. 3 and 5 eyepieces on the short tube to equal the A and C on the English standard respectively. There is no doubt about the disadvantage of deep eyepieces. It is this which handicaps small telescopes and dumpies so much. Just imagine comparing a 12ft. telescope stopped down to 3in., and a 3ft. telescope of 3in. aperture. In order to get a power of 144 in both cases, you would have to use a 1in. eyepiece in one case and $\frac{1}{4}$in. in the other. If the two telescopes came out alike, it would only show how much superior the small one was in reality. Speaking of telescopes, I saw a very remarkable old telescope the other day. Aperture of object-glass, $\frac{5}{8}$in.; focus, 12$\frac{1}{2}$in.; object-glass, a single lens unequal convex (nearly plano-convex). The eyepiece consisted of three bi-convex. The mount the old-fashioned mahogany polygonal tube.—EDWARD M. NELSON.

[56183.]—**Force in Motion.**—In the "E. M." of March 27, "Yama" says, "The rope with a horse pulling at each end will be strained equal to the pull of the strongest of the two horses only," and as I do not see that mistake noticed in the subsequent number, I venture the following. If, instead of horses, we place a little boy at one end of the rope and a strong man at the other, the facts may perhaps be more easily traced. Let them both pull, and the man will drag the boy, by exerting a fraction more effort than the boy is capable of doing, and the strain on the rope is equal to the boy's strength only, and not that of the man. Should not "Yama" have said the weakest instead of the "strongest" of the two horses? Again, his illustration by means of a spring balance is good, but he seems to have miscalled some of the parts. Should not the wall to which the apparatus is hooked represent the strong horse, the spring the rope, and the limited weight of 112lb. the weaker horse? Then we have: 1st, the weight (weak horse) doing all it can; 2nd, the spring (rope) indicating a strain equal to the weak horse or weight; 3rd, the wall (strong horse) capable of resisting much more strain, but unable, in this case, to do so, because the weight, or weak horse, is incapable of exerting it.—ACIER.

[56186.]—**Gum for Micro. Slides.**—Querist asks what is the cement used for postage stamps. I believe it is dextrine, a product obtained by heating starch in the dry state. It is obtainable at the chemists, and is much more convenient for use than gum, being more readily dissolved in water.—M. D.

[56187.]—**To Mr. Bottone.**—By rewinding with finer wire, you have placed more resistance in the way, hence have rendered greater battery power requisite, and will suffer from greater heating effects. Better fill your armature channel with 4oz. or 6oz. of No. 20 double cotton covered, and from 1lb. to 1$\frac{1}{2}$lb. of No. 16 c.c. on the fields. Be careful that the insulator is perfect. Six quart bichromates would give about $\frac{1}{2}$ h.p.—S. BOTTONE.

[56207.]—**Clock Repairing.**—Get a piece of watch mainspring the width of the pallets, and of ordinary thickness, grind away the faces of the pallets a little more than the thickness of the mainspring, then tin-solder the pieces of mainspring to the pallets, square off the edges, and polish the faces.—PENWITH.

[56214.]—**Christofle** — Is German silver, an an alloy of copper, tin, zinc, and a little arsenic. No silver enters into its composition; but Messrs. Christofle, in Paris, used it as the basis of their electro-plated ware: hence the name.—S. BOTTONE.

[56206.]—**Teeth of Wheels.**—Having drawn the pitch circle, and divided it into the number of teeth required, draw from one of these divisions a radius, as A B in Fig. 1. Bisect A B in C, and with C B as a radius describe the semicircle A D B. Bisect C B, in E, and from centre B, with radius B E, draw an arc cutting the semicircle

A D B in F. From A, with radius A F draw the circle G F H, from which the faces of the teeth are to be drawn, with a distance equal to F B. The instrument to which you refer is shown in Fig. 2.

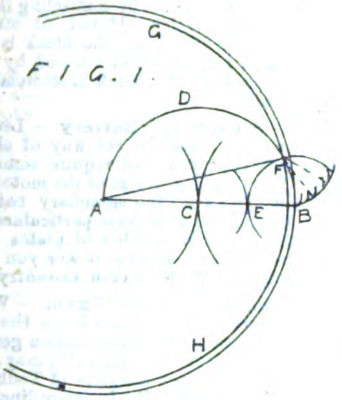

FIG. 1.

The angle is one of 75° 30′, and one of the sides is divided into quarter-inches as shown. To use it, place the plain side upon the radius, with the point touching the pitch circle. The radius for the circle of centres, and the radius for the profile of the tooth

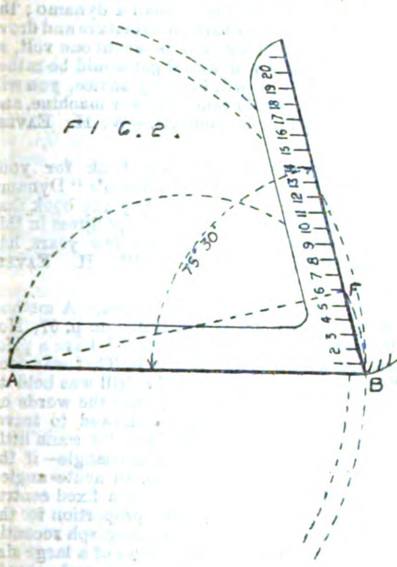

FIG. 2.

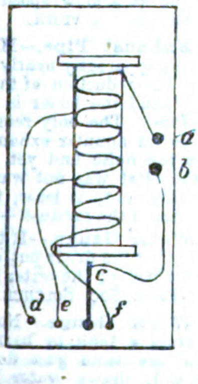
will be found on the graduated edge *e g*. If the radius A B equal 6in., the point F will be found at the sixth mark from B. I don't know the cost of this instrument here; but in the U.S. they cost 2 dols. 50 cents. I made the one I have at a less figure than that; but I seldom use it, as the above rule is so easily applied.—AREFES.

[56219.]—**Edges of Old Violin Belly Splintering.**—Here is a recipe I think will suit you very well. I had it from an old violin maker. Take of gum juniper 4oz., seed-lac 2oz., mastic 2oz., choice benzoin 2oz., Venice turpentine 2oz., rectified spirits of wine 1 quart. Put the whole into a bottle and let it stand for three days, giving it a shake up as often as you like, and it will then be ready for use.—JIM.

[56220.]—**Medical Coil.**—In answer to "Electric" about his coil, he must have two binding screws *a* and *b* for the handles of his coil to be connected to. The beginning of the secondary coil goes to one of these *a*, the other, *b*, goes to the switch *c*. The three studs *d e* and *f* are connected in the following manner: *d* is connected to the middle of the secondary coil, *e* is connected three quarters of the way through secondary, and *f* is connected to the end of secondary, thus enabling "Electric" to alter the power of his coil. The sketch only shows roughly the winding of the secondary coil. Of course, there is much more wire.—TOBY.



[56221.]—**Blue Shadow.**—Presuming that the light of the obscured sun or of the gas flame was reddish yellow, and that what light there was in the shadows was faint white, three possible explanations occur. 1. The shadows appeared blue by contrast. 2. The eye was fatigued to the yellow, and was therefore more sensitive to its complementary, the blue component of the white in the shadows. 3. In faint light the eye is said to be naturally more sensitive to rays of the higher degrees of refrangibility; hence the blue component would be more conspicuous in the faint white of the shadows.—J. BROWN, Belfast.

[56223.]—**Dynamo.**—TO MR. BOTTONE AND OTHERS.—See reply 55723.—S. BOTTONE.

[56227.]—**Vacuum.**—"Nearly a perfect vacuum" is only practically to be obtained by an air-pump—i.e., an exhaust pump. There are other means of doing it, but the above is the most practical. The outside pressure will be (according to the barometric pressure at each moment of time) 15lb. per square inch, or somewhat less. Barometer at abnormal height of 31in. then just 15lb.; if at 28in., then much less than 15lb. Pressure equal on all sides of vessel, top, bottom, and sides. A square vessel of 1ft. cube, with a nearly perfect vacuum, would collapse unless very strongly made. Each side would have a pressure of, say, 2,160lb. thus: 12 × 12 = 144 × 15 = 2,160lb., or nearly one ton. The area of each side, if increased to 13in., would give 2,535lb., or much more than one ton, which is 2,240lb. I cannot enlighten (or darken) "One Who Wants to Know" in his other query.—Z. Y. X.

[56227.]—**Vacuum.**—Either the Sprengel or the Geissler mercury pump is used to obtain the best vacua; but a good ordinary air-pump will reduce the pressure to less than 1oz. per square inch. The pressure on the outside of any vessel is, of course, that of the atmosphere at the time, 15lb. per square inch, more or less. Indiarubber would not make a good joint unless the plates were bolted or pressed together so as to compress it. Greased leather might do better; but a true metal joint well ground or fitted by scraping, and then greased, would be better still. It is difficult to understand what is meant by a "friction of 5lb. per square inch."—J. BROWN, Belfast.

[56228.]—**Storage Batteries.**—I have seen a small storage battery of the following dimensions: 5in. long, 3in. wide, and ¾in. thick. It consists of the following: a cell of lead foil is made of smaller dimensions than those given, and is coated with peroxide of lead, made into a paste with dilute sulphuric acid; inside this cell are a number of thin lead plates, also coated with peroxide of lead, and covered with parchment paper to prevent their touching the lead cell. They are separated from one another by small bits of wood (matches do very well), and the whole of the plates fastened together by an elastic band. In cutting the lead plates you must leave a tongue on one end for connections; the tongue ought to be 4in. long and ¼in. wide. The lead cell must be covered with indiarubber varnish where it is soldered, and when the plates are fixed inside the lead cell a leaden lid must be soldered on, leaving two circular holes ½in. in diameter, one for pouring the liquid into the cell, and the other for the tongues of the lead plates, which should be bound up together so as to form, as it were, one wire. Care must be taken not to let the tongues touch the leaden lid, by inclosing them in a piece of indiarubber tube. The lead cell will form one pole of the battery, and the plates will form the other. The liquid put in the cell is one part of sulphuric acid to 15 parts water. The hole left for the liquid may be closed with a cork after it has been charged, and the holes left for the tongues may be plastered round with guttapercha cement; the whole thing is then put in an ebonite cell of the dimensions given before, having a cover with holes for the terminals to pass through. I don't know whether you can charge it with five granule cells.—TOBY.

[56236.]—**Boring Mill.**—To "INVICTA."—The foundation of the whole machine consists of a casting of a cup shape, the rim of the cup being cast with slots to drop over the studs in the cylinder flange, and the recessing or cupping of the casting being equal to a little more than the thickness of the boring head. The boring bar is a hollow cylinder with a slot cut through the side, so that a screw passing down through the hollow centre engages a nut carried on an arm which passes through the slot and connects the nut and the boring head. Briefly, the whole machine is this—a hollow bar turned on the outside carries the cutter head, which slides a good fit on the outer turned surface of the bar. The one end of the bar has a centre fitting into a bush, which is made to fit the back cylinder cover gland. The other end of the bar passes through the cup-shaped casting, bolting to the cylinder flange, from which the cover has been removed. The piston and rod are, of course, withdrawn. A worm-wheel which, by means of a feather fitting in the slot, already mentioned, in the hollow boring bar, gives the means of turning, a handle being fitted to the screw gearing with the worm-wheel. The internal feed screw is actuated by the well-known star feed, so that the whole machine is of the simplest form. As to cutters, I prefer to, if necessary, take two cuts—a coarse and a finishing cut. I don't think that it would be well to use rough and finishing cutters in the same boring head. Not only so; but it would not be practicable in that case to carry the finishing cut as far as the rough cut in the cylinder bore. A job such as this pays to expend a little time on to do it well.—INVICTA.

[56237.]—**Cylinder.**—I am sorry to have to tell you that the most practical advice I can give you is to discard the cylinder in question altogether. What is worth doing at all is worth doing well, and your cylinder, as it is, is simply useless for any practical purpose. The ports are too small. The steam ports should be at least ¼in. by 2in., or, even better still, ⅜in. by 2in.; the exhaust ¾in. or 1in. by 2in., not less. If you have not bored it, alter the pattern and enlarge the ports to the sizes I name. With the larger ports you could estimate it at nearly 1 h.p. nominal. With the small ports, I should be afraid to say anything about power at all. How is it possible to fill a 3½in. by 6½in. stroke cylinder with anything like a pressure of steam at any speed? It cannot be done. I would feel happy in helping you; but do not ask me to advise on an impossibility. Let me know if you will go in for a new cylinder and proper size port, and I will give you dimensions of every part needful to make the cylinder really useful.—INVICTA.

[56238.]—**New Steam Motor.**—I much regret that the motor in question, not being my property, and also being a patent, I am unable at the moment to give him what he wishes. I have asked the patentee to allow me to forward a set of tracings for publication, and am promised the same shortly. I hope to be able to lay the matter before the readers of this journal in a new form—that is, that I fully hope to be able to say that a special license to make for their own use only, on a nominal royalty, will be at the disposal of bonâ-fide readers of the "E. M.," as I think the invention one likely to be of real practical service to amateurs.—INVICTA.

[56239.]—**Filtering Acids.**—This is a large question. No particular kind of acid is mentioned. Cotton wool would be out of the question for some acids. I would suggest a filter as follows: 1. Bottom layer, asbestos or slag wool, either being nearly "strong-acid" proof; this a good thickness. 2. Fine well-washed river or silver sand. N.B.—"Well washed" means thoroughly washed, till no impurity or salt remains, and should be washed with acid. 3. Fine (very fine) stones also well washed in acid, and then with water. 4. Layers of stones increasing in size by degrees till, 5. Top layer small stones (well washed) less than ¼in. diameter. Every means should be taken to prevent solid matter getting to even a filter made as above, and even above. Filter will have no chance of working well save for a short time, if the matter to be filtered is at all gelatinous, or of that nature.—Z. Y. X.

[56240.]—**Tug.**—I should make such a model into a paddle-boat, not a screw; and from the shallow depth a screw could not be used to utilise the greatest engine and boiler that could be fitted. (For boiler see page 110.) Engines might be paddle ones—oscillators, 2½in. bore and 3½in. stroke—and two cylinders inclined may be used; the paddles may be with advantage 10in. diam., and with floats 4½in. or 5in. wide. If, as you say, the model has fine lines, the engines I name will do all that can be done; and the slides being made to cut off early, the boiler I mention would supply plenty of steam. For such a boat, a pair of slow-moving paddle engines will do better than a screw. And I would just say in passing. Do not in these days think of gearing up the screw shaft of a steamer: direct-acting engines are a long way better than any kind of gearing. I will, if wanted, give you any further assistance in advising on the fittings of your machinery for such a boat.—INVICTA.

[56242.]—**Dynamos.**—The E.M.F. of a given dynamo will depend on the softness of the iron and the ampère turns of wire on it. But having obtained the E.M.F. of a given-size dynamo from a given sample of iron with a given-sized wire, the E.M.F. when the saturating point of the iron is reached is proportionate to the speed; and if the machine be doubled in every dimension (section of wire also, but not number of coils) its efficiency becomes 32 times as great.—S. BOTTONE.

[56242]—**Relation of Electromotive Force of Dynamos to the Size and Speed of Rotation.**—The E.M.F. of a dynamo depends on—1.

The number of turns of conductor on armature. 2. The speed of rotation of armature. 3. The intensity of the magnetic field. If two of these conditions remain constant, the E.M.F. is proportional to the third. The E.M.F. remaining constant, we can alter any of these conditions by altering the others so that the product shall remain the same—that is, the product of the number of revolutions per minute multiplied by the number of turns and multiplied by the intensity of the magnetic field. For example, in a dynamo giving, say, 60 volts—

Let M = Intensity of magnet field = 1
,, R = Revolutions of armature per minute = 900
,, N = Number of turns of conductor on armature = 240;
Then M × R × N = 1 × 900 × 240 = 216,000.

This number may be called a constant for 60 volts in that particular dynamo. Now, if we double M we can halve either R or N, or doubling either R or N can halve M, the product remaining the same. In generators where the intensity of the magnetic field is constant, as in separately-excited dynamos, compound dynamos with constant external resistance, or magneto machines, the E.M.F. is proportional to the speed; but in "shunt" or "series" wound dynamos the E.M.F. increases in a greater proportion to the speed owing to increased current round the field magnets and the consequently increased magnetic field, and is much more complicated. With reference to size of dynamos, according to Gordon, when we know what a machine of a particular type will do we can easily calculate other sizes. If larger, it is safe to consider that the strength of the magnetic field, the proportions of the magnets remaining the same, is proportional to their weight, and that the proportion of armature to magnets remains unaltered; if smaller than the typical machine the magnets must be somewhat larger than the above rule. If the E.M.F. of the larger machine is to be the same as the typical, the wire on armature must be proportionately shorter and thicker, the simplest way of working is to calculate what would be the E.M.F. if the wire had been the same as on the typical machine, and then calculate the proper size of wire by the following rules:—1. With the armature coil carrying a given volume of wire, then, all other things being equal, the E.M.F. is proportional to the length of wire. 2. The volume of wire on the armature coil is proportional to the length of the wire multiplied by its section; whence, with a given armature coil, the E.M.F. will be inversely proportional to the section of the wire. Professor Thompson has demonstrated theoretically the relation of size to efficiency, assuming that the size of the machine be increased $n$ times in every dimension, and that though the dimensions are increased the velocity of rotation remains the same, and the intensity of the magnetic field per square centimetre remains constant. If the linear dimensions be $n$ times as great in the larger machine as in the smaller, the area it stands on will be increased $n^2$ times, and its volume and weight $n^3$ times. The cost will be less than $n^3$ but more than $n$ times. If the same increase of dimensions in the armature coils be observed, the number of layers and of turns remaining the same as before, there will be on the armature coils a length $n$ times as great, and the area of cross section of the wire will be $n^2$ times as great as before; the resistance of these coils will be $\frac{1}{n}$th part of the original resistance. If the field-magnet coils are increased similarly, they will be only $\frac{1}{n}$th the resistance of those of the original machine. The E.M.F. will be increased $n^2$ times, the speed of the armature being the same. If the larger machine is "series" wound, an E.M.F. $n^2$, working through $\frac{1}{n}$ resistance, will give a current $n^3$ times as great as before. In this respect, as the iron of our field magnets is $n^3$ times as great in mass, we need not so nearly saturate it as before to gain the same magnetic field, or to get $n^2$ times the area of surface magnetised to the former average intensity per square centimetre. Hence the number of coils may be reduced in the proportion of $n^2$ to $n^3$, or to $\frac{1}{n}$th of its already diminished value, correspondingly reducing the resistance on which work has to be done. As in the larger machine, therefore, the E.M.F. is increased $n^2$ times, and the current $n^3$ times, the work of the machine will be $n^3 \times n^2 = n^5$ times greater than with the smaller machine, or, a machine doubled in its linear dimensions will not cost eight times as much, and will be electrically thirty-two times more powerful than the smaller machine. If the machine be "shunt" wound, then to produce the field of force of $n^2$ times, as many square centimetres area will require (if the E.M.F. be $n^2$ times as great) that the absolute strength of the current remain the same in field magnet coils. This can be effected by using wire of the same size as before, and increasing its length $n^2$ times to allow for $n$ times as many turns, of $n$ times as great a diameter each, in the same number of layers as before. The current being the same, therefore, in the shunt circuit as before; but under $n^2$ the E.M.F., the work here is only $n^2$ times as great, whilst in the whole machine it is $n^5$ times greater than the smaller machine. According to Gordon, in practice the result does not much exceed the third power, or cube, of the linear dimensions, and a practical rule is given that the output will be proportioned to the weight of the machine.—Eugene Brown.

[56254.]—**Netting Square Mesh.**—Commence from a single loop, out of which you will make two, by going twice round the mesh stick, and tying a knot each time; slip off, and go on again repeating the "letting out" at each end until you have got your width. To keep the net equal in width, you will now let out one side only, and "draw in" the other. By "drawing in" I mean take two meshes into one. When the length is obtained, measuring from the very beginning, you will have only to put on the other corner, which is done by taking in two meshes into one on both sides (in fact directly opposite to the manner in which you began) until you have netted yourself out. Now find your four corners and pull out straight, when you will find your meshes are square, although you made them as diamonds.—R. H.

[56256.]—**Valve Gear.**—I would refer the querist to my replies to Nos. 56104 and 56171, pages 87 and 89. Anything further I can do to assist him or others in a practical direction I will do most willingly: but I do not want them to spend their money uselessly. I have had some experience that cost me very dear, and I would gladly save others the outlay I have myself gone to.—Invicta.

[56258.] — **Reflecting Galvanometer.**— The reels of my galvanometer are of boxwood, $2\frac{3}{8}$in dia., by 1in. wide; but I might, perhaps, have made them larger with advantage. No. 1 has 57 turns of No. 14 wire; No. 2 is of No. 24 wire; and No. 3 has about 4,000 turns of No. 35 wire. The wire should be silk covered, baked dry, and run through melted paraffin in winding on. There is about $\frac{1}{2}$lb. of wire on each reel. Using coil 2 the instrument will detect a difference of ·000013 in one ohm with the Wheatstone bridge. Of course the best size of coils, wire, &c., depends on the work to be done.—J. Brown, Belfast.

[56261.]—**Selenite.**—This substance is sulphate of lime: the quantity mentioned would be equivalent to about 12 degrees of hardness.—Asa.

[56261.]—**Selenite.**—Is "Bennett" correct? Is plaster of Paris selenite? I do not think so. Again, has J. H. Hurst, of Salford, given its true chemical composition? I think not. He has left me the aqua which so pleased the servant when the doctor had prescribed for her, saying that her prescription was like her master's, and therefore she had faith in the doctor. Mr. Hurst should have stated how long it would take for 25 barrels of water to take up 2lb. weight of selenite, and under what conditions.—Z. Y. X.

[56264.]—**Mechanics.**—The total resistance is 500lb., and this is overcome at the rate of 1,760ft. per minute: hence the total work done in that time is 880,000ft.-lb., and dividing this by 33,000, we obtain 26·6 as the h.p. of the engine. The data given are, however, not very accurate, for the resistance of a train running 20 miles per hour is 15·5lb., not 10lb., and trains usually weigh more than 50 tons; the engine and tender alone frequently weigh 60, and of course their weight has to be included.—Wm. John Grey, F.C.S., Analytical Chemist, Newcastle-on-Tyne.

[56264.]—**Mechanics.**—The friction being 10lb. to the ton, the engine must exert a traction of 500lb. Now 500lb. 20 miles an hour

$$= \frac{500 \times 20 \times 3 \times 1760}{60} \text{ ft.-lb. per minute.}$$

This, divided by 33,000 gives $26\frac{2}{3}$ horse-power.—Geo. A. Walton.

[56264.]—**Mechanics.**—Total frictional resistance = 500lb. Work done per minute

$$= \frac{500 \times 5280 \times 20}{60} \text{ foot-pounds.}$$

$$\therefore \text{ horse-power} = \frac{500 \times 5280 \times 20}{60 \times 33000} = 26{\cdot}6.$$

—Jno. M. Adams.

[56268.]—**Shocking Coil.**—To "C. J. R."—Doubtless the two joints in your secondary wire are the cause of your inability to obtain shocks from that end of the coil near to which are the joints, on account of the increased, and therefore too great, resistance offered by them, owing, perhaps, to their being not good, electrically speaking. The only way that seems to me to thoroughly overcome the difficulty—but at the same time a very annoying way, especially if the joints are at the end where you commenced to wind on the secondary wire—is to unwind the wire as far as necessary, cut off the joined portion, and so have the secondary wire entire throughout its length. If this does not give the required result, write again, and I will see from experiment what can be done, as I have a half-built coil on hand.—J. Kean, Northampton.

[56268.]—**Shocking Coil.**—This looks as if the secondary was broken near the end which gives the small effect, and that the discharge passed by some badly insulated path to earth from the broken end, and so through the body of the operator. Try if the secondary is continuous by connecting it with a battery and galvanometer. If not, of course, it will have to be unwound till the break is found. The fault might, I think, also be caused by a good earth connection without a break in secondary.—J. Brown, Belfast.

[56273.] — **Secondary Battery.** — Leclanché cells will not do much in the way of charging secondary batteries; you will require some quart Bunsens. You do not give size of the motor or the length of time you want the secondary battery to work it. If you will give these particulars, I will tell you the size and number of plates for the secondary battery, and also the power you will require to charge it.—W. H. Eaves, Coventry.

[56274.]—**London Int.Sc.Exam.**—Wilson's "Solid Geometry" (Macmillan) is, on the whole, the best book to get up the mensuration generally, and the "Geometry of the Sphere"; may supplement with the first three chapters of Todhunter's "Spherical Trigonometry." In co-ordinate geometry the best book for the purpose is Le Sueur's "Straight Line and Circle" (Ballière's Cheap Aids Series).—B. A.

[56283.]—**Small Dynamo.**—I am sorry to inform you that when you have made your dynamo with a Catella armature it will be quite useless, as near as I can calculate, for so small a dynamo; the E.M.F., if you had 100 bars on armature and drove it at 3,000 per minute, would be about one volt, so the amount of light you would get would be rather microscopic. If you will take my advice, you will buy the castings of a 30 candle-power machine, and fit it up and wind it yourself.—W. H. Eaves, Coventry.

[56284.]—**Dynamo.**—The best book for your purpose will be Prof. S. P. Thompson's "Dynamo Electric Machinery." Do not buy any book that is more than two years old, as the progress in this branch of science within the last few years has been something enormous.—W. H. Eaves, Coventry.

[56285.]—**Drilling Square Holes.**—A method of drilling square holes is illustrated on p. 57, No. 705, the patent of Mr. J. Hall, and I have a piece of brass rod with a square hole in it. That was done by allowing the part in which the drill was held to slide slightly on the chuck, or to use the words on the page mentioned, the drill is allowed to travel automatically in a horizontal plane for some little distance. The drill in section is a triangle—if the longest side is taken as the base, an acute-angled triangle, and it does not rotate on a fixed central point, but diverges somewhat in proportion to the size of the hole. I have seen a paragraph recently about a drill for boring square holes of a large size in wood. It is an American invention, and according to the description, little saws attached to it clear out the corners.—Nun. Dor.

[56285.] — **Drilling Square Holes.**—I have also received particulars; but no piece of the metal with the hole cut. It certainly is very clear that if we cannot make it, we can obtain it at a price. If this should meet the eye of Mr. Bateman, of Greenwich, perhaps he would send illlustrations of the one he makes or supplies.—Fell. Soc. Science.

[56288.]—**Crank Shaft.**—1. Even for a model I like plenty of metal in the crank; therefore, let the round part of crank shaft be $\frac{5}{16}$in. diam.; webs of crank, $\frac{3}{8}$in. by $\frac{3}{8}$in. Do you mean to cut out of the solid or build up in parts? If properly done, the last is far the easiest for an amateur; and at best it is a troublesome job to turn up from the solid a crank. 2. If a horizontal engine, it is not necessary to balance the crank; but if a vertical engine, the crank and all the motion work should be balanced, or at a slow speed the engine will work spasmodically.—Invicta.

[56289.]—**Exhaust Pipe.**—Many plans have been tried; but apparently nearly all fail from the fact that with the reduction of the noise, the blast is also lessened, and the boiler is not able to keep steam as before. The only remedy I could suggest would be an annular exhaust, which would partly reduce the noise and yet not decrease the draft. If the blast was not wanted to urge the fire, I could tell you of, at least, two good remedies for the noise of the exhaust.—Invicta.

[56290.]—**Water Gauge.**—If the water is left "turned on" after the fire is put out, a vacuum is produced in the boiler; the water in the tank will rush into it.—Fell. Soc. Science.

[56290.] **Water Gauge.**—No doubt you feed the engine from a tank or barrel of good size. Hence, when the steam goes down, the partial vacuum formed, draws water from the tank through the pump valves into the boiler, thus filling it up to a height much beyond the proper level. Owing to your engine being no doubt steamjacketed, the additional volume of water does not produce any marked effect. Remedy: Have a good stop valve or plug cock on the suction, and if a part of the exhaust is returned into the water tank to heat the feed, have a cock on this also. I have had a horizontal boiler that was guilty of the same trick, and once or twice with most annoying results. If this is not the cause, write again.—INVICTA.

[56290.]—**Water Gauge.**—I think the reason why the water in the gauge glass rises out of sight every night is that as the steam in the boiler condenses during the night, and thus forms a vacuum, the water from the feed tank or barrel is forced by the pressure of the atmosphere up the indiarubber feed pipe, raises the valves of the feed pump, and fills the boiler until the equilibrium is restored. Remedy: Take the suction pipe out of barrel or tank.—G. B. P.

[56294.]—**Chemical.**—The formula, when chlorine is passed through milk of lime, is—

$$2CaH_2O_2 + 2Cl_2 = 2H_2O + CaCl_2 + CaCl_2O_2$$

Both calcium chloride and calcium hypochlorite are, therefore, formed.—R. A. R. BENNETT.

[56294.]—**Chemical.**—When chlorine is passed into a solution of calcic hydrate (milk of lime), calcic chlorate and calcic chloride are formed according to the equation:

$$6\ CaHo_2 + 6Cl_2 \left\{\begin{matrix} OCl \\ O \\ O \\ OCl \end{matrix}\right. \!\!\!\! CaO'' + 5\ CaCl_2 + 6\ OH_2$$

Calcic chlorate. Calcic chloride.

By which it will be seen that no calcic hypochlorite is formed.—J. KEAN, Northampton.

[56294.]—**Chemical.**—When chlorine is passed into *cold* milk of lime, calcium hypochlorite and calcium chloride are formed thus: $2CaH_2O_2 + 2Cl_2 = Ca(ClO)_2 + CaCl_2 + 2H_2O$. This solution is used in the Lancashire bleach works for bleaching, under the name of bleaching liquor. When *hot* milk of lime is used, calcium chlorate and chloride are the products, thus: $6CaH_2O_2 + 6Cl_2 = Ca(ClO_3)_2 + 5\ CaCl_2 + 6\ H_2O$.—GEORGE H. HURST, Salford.

[56294.—**Chemical.**—When chlorine gas is passed into cold milk of lime, the following reaction occurs:

$$\underset{148}{2CaH_2O_2} + \underset{142}{2Cl_2} = \underset{143}{Ca(OCl)_2} + \underset{111}{CaCl_2} + \underset{36}{2H_2O} \quad \underset{290}{}$$

On boiling the liquid the hypochlorite decomposes thus:

$$\underset{429}{3Ca(OCl)_2} = \underset{207}{Ca(O_3Cl)_2} + \underset{222}{2CaCl_2}$$

And on the addition of potassium chloride double decomposition occurs between it and the calcium chlorate, resulting in the formation of potassium chlorate and calcium chloride, which are easily separated by crystallisation. If chlorine be passed through boiling milk of lime, calcium chlorate is formed thus:

$$\underset{444}{6CaH_2O_2} + \underset{426}{6Cl_2} = \underset{207}{Ca(O_3Cl)_2} + \underset{555}{5CaCl_2} + \underset{108}{6H_2O} \quad \underset{870}{}$$

—WM. JOHN GREY, analytical chemist, Newcastle-on-Tyne.

[56296.]—**Sand Blast.**—"An Old Subscriber" does not say for what purpose he wishes to use the sand blast. Steam is used when sharpening files, and compressed air for glass; the latter has been tried on my hand, which, being soft, had a very different effect to what it has on glass. It felt not very unlike an electric shock.—FELL. SOC. SCIENCE.

[56298.]—**Records of the Past.**—There are English translations of the Assyrian and Egyptian monuments; there are six volumes of translations of Assyrian texts, and as many of Egyptian (published by Sam. Bagster and Sons), each volume, 3s. 6d., may be had separately; they are all of great interest and value. The Assyrian series includes annals, legends (some of which touch the Biblical history), poetry, charms, exorcisms, omens, hymns, prayers, incantations, proverbs, public documents, &c.—G. J. W.

[56300.]—**Violoncello.**—The dimensions are as follows:—Divide the length of back into 72 parts; at the 42nd division from the top strike a circle with a radius of 4½ parts, the wood within this circle is reduced to 1 part in thickness; from the same point describe another circle, with a radius of 12 parts, and reduce wood gradually to ¾ part; from this circle reduce gradually to ½ part at the edges of back. The belly is slightly thinner. Ribs, head, and neck, must be purchased. Wood is bent after steaming, or on hot irons. Moulds are of various kinds. Length of bass bar 36 parts, or if belly is thin, longer. Cut soundholes out with a fine fret saw. The above are the dimensions given in Otto's book. I have generally made the figure of the thick part of the tables of an oblong shape in preference to a circle.—T. LISLE.

[56301.]—**Flowerpots.**—In steel-pot making I have seen the mould washed over each time with what appeared to be a thick oil. It seemed to be a strongly carbonaceous oil. All this disappeared when the pots were, after drying, burnt.—Z. Y. X.

[56301.]—**Flowerpots.**—Presuming the moulds are of hardened cast iron, you will best be able to see how plastic clayware is caused to leave such moulds (using paraffin) if you pay a visit to any of the spur works in Staffordshire. The very fine points of the spurs and stilts used in placing glazed earthenware are thus easily liberated from the iron mould, the plunging die working at a terrific rate, and a spur is made completely at every two strokes downward. Accept my thanks for the information as to red ware. Pardon me asking further how the flowerpots are placed in the kiln? Also what is the time of firing, the maximum temperature, and the means of ascertaining when this is reached.—POTTERY TECH.

[56302.]—**Japan.**—This can be stripped off with an old plane iron. That is what japanners use; finish off with coarse emery cloth.—T. LISLE.

[56305.]—**Albo-Carbon.**—It is naphthalene $C_{10}\ H_8$, and boils at 218° C. It melts at 79° C., and has a peculiar odour; burns with a white smoky flame, and in the gaseous state is not inflammable in the absence of oxygen or common air. In its melted state, however, it absorbs air largely, and added to common gas produces a whiter and more luminous flame. Gas companies would like to keep as much as they can in their gas, but, as a matter of fact, it condenses out and helps to block the pipes. A full account of the original patent in No. 706.—NUN. DOR.

[56306.]—**Boring Mill.**—To "INVICTA."—This query appeared on page 90, under No. 56236, and which I have noticed under that number.—INVICTA.

[56309.]—**Parallaxes of Stars, &c.**—Would this querist kindly explain which year is to be considered A.D. 0? His query is a very nice one as it stands; but it would be interesting to learn what the year 0 was like.—NUN. DOR.

[56310.]—**Coil.**—The condenser is usually attached to coils which have primary and secondary layers, otherwise called induction coils. If your coil is of this class, you can certainly attach condenser, and it will give you more shock than you desire; but it has been repeated again and again, that condensers are never used for giving shocks. 2. The melting heat of nickel is about the same as that of wrought iron.—BOBADIL.

[56310.]—**Coil.**—Yes; a condenser can be attached to a shocking coil, and if "Melts" will refer to the "E.M." for March 20 last, No. 1,044, and in reply to query 56037, p. 66, he will find my diagram and description, which will, I think, give all necessary information. Yes, again; a condenser does materially increase the strength of a shock; and should "Melts" require the theoretical explanation of its action, I shall be pleased to give it. Referring to the second part of his question, Buckmaster's "Advanced Chemistry" gives nickel as rather more fusible than iron (i.e., fuses at a lower temperature), while Dr. Thompson says: "Nickel fuses at a very high temperature, about 3000° F.; iron fuses at about 2760° F.—J. KEAN, Northampton.

## UNANSWERED QUERIES.

*The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information hey can for the benefit of their fellow contributors.*

## QUERIES.

[56311.]—**Chemical.**—Will some chemical friend inform me what amount of barium nitrate should be theoretically produced from one ton of sodium nitrate, and what quantity of sulphuric acid, of 1,840 gravity would be required to convert the ton of soda into nitric acid, and what quantity of nitric acid, of 1,420 gravity, should be theoretically produced?—IGNORAMUS.

[56312.]—**Distempering.**—Will some of our decorator friends give me their opinion as to distempering ceilings, and recipe for same, also as to what books there are published on decorating and painting, as to colours?—E. BUTLER.

[56313.]—**Cylinder.**—Will any fellow-reader kindly inform me what alloy of gun-metal would be suitable for a steam cylinder of 3in. bore, 5in. stroke, to work at 50lb. to the square inch, and 100 revolutions per minute, also the thickness required?—W. W. P. R.

[57314.]—**Strength of Gear Wheels.**—Will some of our practical readers inform me of the strength or pitch of gear wheels, necessary to swing 5cwt.; big wheel to be about 15in. diameter, small 3in.? I want them made as light as possible, and can be made with side cap or solid edge.—C. B.

[56315.]—**Anemometer.**—Will some kind reader describe the simplest train of wheels, with or without screw, to register the revolution of anemometer, and if it could be started from zero at pleasure? What I have seen, is something like the index of a gas meter, and I should like to know the maker of them.—WIND.

[56316.]—**Eight-inch Spark Coil.**—At p. 389, of the "E.M." for 4th January, 1884, there is a description of a very successful coil, giving this spark with five pint Groves. As its maker, Ernest Baugh, stated he was going to try quarts instead of pints, may I ask him what was the result, as I intend, when I have time, trying to construct a similar coil with his for a model?—B. HARCOURT.

[56317.]—**Royal Exhibitions and Scholarships.**—Will Mr. W. J. Grey, F.C.S., or any other kind reader, please say what situations, and the salaries attached to them, are open to royal exhibitioners, &c., who have obtained the associateship of the Royal School of Mines? I am contemplating making an effort to obtain one of the scholarships, but before doing so, would like to know my future prospects in case of success.—ELDHIN.

[56318.]—**Owls.**—Being completely over-run with rats, mice, and moles, and finding cats quite insufficient to exterminate them, I have been recommended by a friend to keep a pair of barn owls in a convenient spot. He had no practical experience in the matter, so I wish to inquire whether any correspondent can give any hints on the subject? Are these birds easily domesticated, and should they receive any food besides what they can themselves procure? I suppose there would be no difficulty in getting them.—AGRICOLA.

[56319.]—**Expansion Valve.**—I should be obliged if some reader will give me an explanation, with diagram, of a simple method of determining a variable cut-off.—SLIDE.

[56320.]—**Dynamo.**—Will some one kindly say about how long it would take the small dynamo, described by Mr. Bottone in former vols. ("The Dynamo: How Made and How Used"), to charge the accumulator shown on p. 28, Vol. XL., sufficient to illuminate the lamps, also shown, for three or four hours?—MICROSCOPIST.

[56321.]—**Indicator Diagram Paper.**—It will be a great favour if any of your scientific correspondents can inform me as to the chemical composition of the substance used in the preparation of the paper employed in taking indicator diagrams? I have had occasion to use the above very much of late, and would like to know the action which takes place between the brass pencil and the prepared paper.—VALLEYFIELD.

[56322.]—**Miranda Pianista.**—There is being formed a company to work or manufacture the "Miranda Pianista." Has anyone heard it or seen it, and is it a modification of "Thibouville's Pianistas" for playing the piano? Would some one who knows give me some particulars, and oblige others as well as—VULCANITE.

[56323.]—**Vegetarianism.**—I have adopted a vegetarian diet, and would thank some experienced reader to supply (through your journal) a vegetarian fare that would admit of, at least, two or three changes in the week, and allow of substitutes for vegetables that do not remain long in season; also the manner of cooking by which they are most easy of digestion? The name of a book or books that give the information sought would oblige.—A REGULAR READER.

[56324.]—**Sunlight at Great Depths.**—Is it known at what depth in the sea sunlight is wholly wanting? Are there any data, from actual experiments on the light-absorbing qualities of water, whereby this question may be answered with a fair approach to exactness?—B. A.

[56325.]—**Gyroscope.**—Can and will anyone kindly inform me of the approximate initial and terminal operative velocities of a Foucault's gyroscope, and also of the weight and diam. of disc usually made, or of best advantage? The lowest velocity at which a given disc will show the earth's rotation is the point most desired to be learned. How would 10,000 revs. per min. on a 3in. disc of 2lb. rim be for an approximation?—GYRO.

[56326.]—**Sketching.**—Can anyone favour me with a description of a small portable instrument which will enable me to measure approximately the size of distant objects as seen with the naked eye? It is not necessary to indicate the exact dimensions, but only the relative size. I want it for sketching purposes.—ARTIST.

[56327.]—**Transferring Pictures to Glass.**—Will any reader tell me how I can transfer pictures to glass, such as chromo or oleographs? I have seen them as if they were painted on the glass.—C. P.

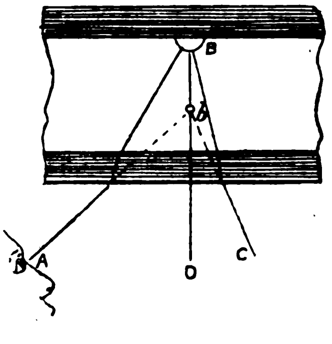
[56328.]—**Vertical Boiler.**—The top plate of a 4 h.-p. vertical boiler is very rusty, and scaled round about the chimney base; it is worked at 60lb. pressure. How can I find the thickness of the plate? Would it be wise to drill a hole or not? I am afraid it is not quite safe.—Tom.

[56329.]—**Crank Throw.**—I have a cylinder 6in. stroke, my crank being 2½in. in webs from centre to centre. I wish to know if that crank would suit cylinder, or must it be 6in., the same as cylinder? Will some kind reader help me in the same?—H. B.

[56330.]—**Soluble Oil.**—Ordinary soluble oil, when mixed with Epsom salts and China clay, for the finishing of grey goods, and boiled, forms an insoluble magnesia soap, which causes the whole mixture to become curdy; but there is a soluble oil in the market which, when boiled with Epsom salts and China clay, forms an even emulsion absolutely free from curdy particles. Can any reader inform me how this soluble oil is prepared?—An Inquirer.

[56331.]—**Chimney Pipe.**—A 4in. cast-iron flue-pipe from a small heating stove, passes vertically through a 4in. hole, cut in one of the slates of the slanting roof above said stove. Rain beating against part of pipe outside, runs down its side and through the hole in stove, and so within doors. Wanted to know how to make a tight joint in roof? Soldering on a zinc or copper sheet won't do, because of heat melting solder; putty won't do, because slight vibration of pipe with wind, causes cracks in putty.—H.

[56332.]—**Optical.**—The sketch represents part of a glass spirit level. B is the bubble. If looked at from A, the bubble appears to be in the line A *b*, cutting the normal B D in *b*. Am I correct in assuming that if viewed from any other point C, the line of sight will apparently cut B D in the same point *b*, as shown? Also please show me how to calculate the position of *b*?—Glatton.



[56333.]—**Scale Scoops.**—Will some of your mechanical correspondents kindly assist by giving hints upon the above? How they are dished? I have got some boxes to make similar to scale scoops, they have to be made out of sheet iron 1/16in. thick, 1ft. 10in. long, 9in. wide, and 5in. deep, they must not be hammer-marked. If they have to be pressed, please to send sketch of castings, and say if could be done with hand-power.—J. W.

[56334.]—**Launch Engine.**—To "Invicta" and Others.—I have a pair of 4½ by 5 diagonal launch engines that I wish to put into a new boat, but am afraid they will not drive her at a reasonable speed. Could I increase the power by introducing a third cylinder to utilise the exhaust? Is it practicable?—Medlock.

[56335.]—**Potter's Kiln.**—I am desirous of building a potter's kiln about 4ft. square inside to burn terra-cotta. Will Mr. S. Arlidge or "Pottery Tech." give me a sketch or any advice upon the subject?—J. Townley.

[56336.]—**Glucose.**—Would any reader kindly give me the simplest process and test for the identification of glucose when combined with other substances?—Simon Fairfax, Glasgow.

[56337.]—**Electrical.**—Will any reader kindly inform me if I can ring two bells on one circuit—viz., one bell at top, one at bottom, with two brushes, the battery at one end with two wires? I can do it with the reversible pushes with battery at each end, but it is inconvenient.—Crutesta.

[56338.]—**Pattern-Making.**—Will "J. H." or any other kindly let me know the way to make the patterns for the carriage and slide-rest combined of a 6in. self-acting sliding, surfacing, and screw-cutting lathe, with independent back shaft, the carriage to have cross-slide cast on it, and the horizontal slide to swivel round for turning cones; the rack to be in front of bed just below the carriage, and the leading screw below the rack; and what number of threads per 1in. on leading screw, and whether V or square threads are best, and what diam. of screw? And how can I put in the back shaft of running head, as it has oblong holes 2in. by ¾in., and my wheels are bored out 1⅛in.; and the way to put on pinion on mandrel?—Busby.

[56339.]—**Stops to Photo. Lenses.**—As Mr. Pumphrey recommended, I procured the "Year Book," but can make nothing of the diagram of stops contained therein. Seems to be a misprint in the directions. See second line from bottom, printed matter. Again, I do not know what is the "equivalent" focus of my lens. I only know that the solar focus is 5in. Will Mr. Pumphrey kindly make the matter plainer?—Gwent.

[56340.]—**To Mr. Bottone or Others.**—I am making small dynamo, of which the F. magnets measure 2¾ high, by 3½ wide. Where wire is wound and small laminated armature, 3¼, by 1¾; I am going to wind d.c.c. on F.M.'s, and 6oz. of 20 d.c.c., on armature. Will you kindly say if that is right, and whether there is a particular way in winding F.M.'s? If I commence at bottom and finish at bottom, will it be right? and whether I connect the first parts of wire on fields to brushes or parts, and I suppose either the first or last two ends are connected together of fields? I want to light as many 2½ lamps as I can. Kindly say how many, and what speed to run at, and how many volts lamps are to be? The armature, is, I suppose, wound, and the two ends connected together; is that right, or is it wound any particular way, so as to get the current to run to the commutator? Do I screw any binding screws into pillars supporting brushes for connecting wire to lamps, I want the same for lighting small cottage?—A Plumber.

[56341.]—**Cheap Gas.**—To "Invicta."—On p. 61 you use the phrase "compared with coal gas, it does not cost me 9d. a 1,000 cubic feet." If the gas costs less than 9d. a thousand (whether compound with coal gas or not) we should be very glad to have more particulars. Will "Invicta" give them, or refer to the makers of the apparatus?—Glatton.

[56342.]—**Public Lighting.**—Could any readers of the "E.M." furnish me with the names of any places which use petroleum for street lamps instead of gas, either from want of gas, or inability to agree with the gas company?—Surveyor.

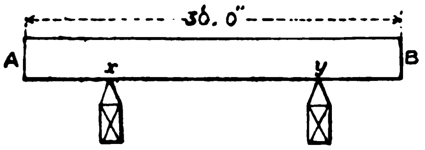
[56343.]—**Electrical.**—To W. H. Eaves.—Will W. H. E. kindly reply to query 56114 in "ours" of March 13, entitled "Electro-plating Dynamo"? Will he also state how to make a galvanometer to give a comparative idea of the strength of current, as the one I have is deflected from north and south to east and west, and the needle remains at E. and W., whether I send a current through it from one cell or from twenty cells?—Faraday.

[56344.]—**Rubber Belting.**—What is the best method of joining ends of the above? If I rip a 4in. belt down into two or more, will its efficacy as a narrower strap be affected? What is the best manner of cutting it?—J. J. H.

[56345.]—**Legal.**—A., B., C., and D. are executors under a will. B., C., and D. had a reversionary interest in £12,000; C. has had to sign away his interest owing to a debt, and insists on the securities being placed at a bank or in some place of security. A., B., and D. wish that A. should keep them in his possession. Can C. insist on his wish, or does the opinion or wish of the majority over-ride that of one executor?—J. C. B.

[56346.]—**Seller's Screw Thread.**—Will any of our readers oblige with a description of this screw thread?—Screw.

[56347.]—**Centre of Percussion.**—A beam A B is supported in two places *x y*, and each of these supports alternately rises and falls, causing vibration to beam. It is required to know the two points of support at which the vibration is the smallest degree felt by beam?—R. J.



[56348.]—**Colouring Terracotta.**—Can any of your readers inform me by what simple process I can colour bricks or terracotta, so that the face will burn red? What chemical is used, and how is it applied? The natural clay burns a light red colour, and we want a deep red for the face. Also how are red roofing ridge tiles made?—X. Y. Z.

[56349.]—**Portland Cement Concrete.**—Can any of your readers inform me how the red colour is given to the red Portland Cement concrete slabs now in use, and whether the same means would answer to give a permanent red colour to Portland cement used in coating the exterior of a house? Also, whether the mixture of the cement with crushed red bricks, instead of the usual washed sand, would be of any use, and if there be any means of making a permanent red rough-cast or pebble dash?—Portland.

[56350.]—**Electro-plating.**—Will some reader kindly tell me how I can prevent the silver peeling off from some terminals, &c., which I have been silver plating? I used a small Daniell's cell and ½oz. of pure silver on anode, and have put a piece of wet string into the circuit to lessen the current. Also, how long ought the articles to be silvered be left in the solution?—Cyanide.

[56351.—**Worm in Mahogany.**—I am making a bookcase, and some of the wood I have bought is slightly perforated with worm holes. Is the worm likely to spread, and should the wood be discarded on this account?—G. S.

[56352.]—**Lacquer for Lamp.**—I have a lamp consisting of an old tin moderator reservoir with a modern paraffin burner attached, which gives a fine light. The lacquer is worn off the tin body, leaving it very shabby. What can I coat it with to make it presentable? I have tried Brunswick black, but the paraffin washes it off.—G. S.

[56353.]—**Orrery or Planetarium.**—Is there any work in which I can find the number of teeth in the various wheels required for a planetarium, so as to give the correct motions of the planets and their satellites? Or can any reader give me the numbers?—Planetarium.

[56354.]—**Turning Cannel Coal.**—How can I make fancy hollow goods from cannel coal? I have the use of a lathe, but find the cannel so brittle that it breaks off in large pieces, and I do not know of any cement that will hold the broken parts together.—Ryhope.

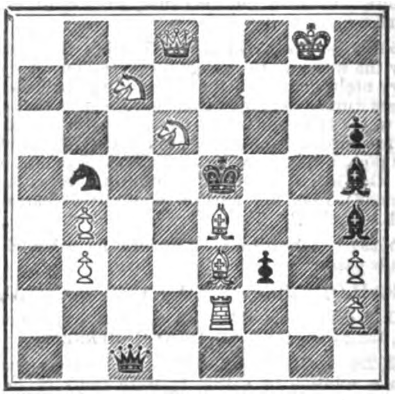
[56355.]—**Legal.**—Would one of our legal correspondents kindly answer the following? Can a man, on leaving a situation, claim references that had been written for and obtained by his late employer? Or are the references considered a private communication and not recoverable? Whether the original document is bound to be produced, or whether a copy can be substituted?—Engineer.

## CHESS.

All Communications for this department must be addressed to J. Pierce, Llandwrog, Carnavon.

### PROBLEM DCCCCXXXIV.—Tyro.

*Black.*



*White.* [11+7

White to play and mate in three moves.

Solution to 932.

| *White.* | *Black.* |
|---|---|
| 1. K-R 6 | 1. Anything |
| 2. Q, R, or Kt mates | |

(Four variations.)

### NOTICES TO CORRESPONDENTS.

Correct Solutions to 932 by Rev. W. Anderson (Old Romney), E. Stanley Follwell, and A. O. E. Lecluse; to 431 by H. Culmer (second solution).

A. O. E. Lecluse.—Your first move in solution of 931 is correct, but you have not given Black his best defence, which is 1. P-K 3. Name entered.

M.—929 is a *two*-move problem, and is quite sound. If 1. K-Kt 3, 2. Kt-B 4 mate; if 1. Kt takes Kt, 2. Q-Q Kt sq; if 1. K-K 5, 2. Kt-B 3 mate.

J. E. Piper.—In 932, if 1. R takes B, 1. B-Kt 4, and there is no mate.

E. S. Follwell.—We have entered your name for Tourney.

E. Hughes.—In 932, if 1. Q-K B 8 there is no mate, if 1. B-K 3 or B takes Q R P.

H. A., Harlesrood.—Far too easy and simple.

Mr. H. F. L. Meyer, the composer of problem 932, proposes to make it right by adding B P at K B 4, to P at K B 3, and removing B P at K-Kt 4.

The following Tourney problems have been duly received:—"Measure for Measure," "Ariadne," "Beware of the Dog," and "Salutation."

Check.—Revised No. 5 has been substituted.

Mr. A. Briggs has been kind enough to offer as an additional prize in Problem Tourney a Chess Diagram Stamp—vulcanised indiarubber, mounted on brass, box pad, ink, &c.—value, 5s. 6d.

## ANSWERS TO CORRESPONDENTS.

⁂ *All communications should be addressed to the* Editor *of the* English Mechanic, 332, *Strand, W.C.*

### HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

⁂ Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, April 8, and unacknowledged elsewhere:—

R. Lloyd and Co.—J. H. Thompson.—X. Y. Z.—H. H.—Epworth.—A. W. H.—Pedestrian.—Boilermaker, Sunderland.—Tyro.—W. Habgood.—G. L. T.—E. P. Read.—P. Ward.—Ora et Labora.—Snooks.—Urgent.—Bike.—Micro.—Meteor.—Wear.—Phono.—In the Dark.—Fred Hunt.—A. F. Miller.—Beginner.—R. Inwards.—Chemical Work.—Clement H. Wragge.—S. E. Hunt.—Invicta.

G. H. B. (As you do not say what the query was about we cannot pretend to remember it. Perhaps it was answered to "G. U. B." in this column for March 13.)—Rustic. (Tracing-paper, or any varnished paper, will do.)—M. (Given many times. See list of Back Numbers last week, and answer to "T. B." on p. 114.)

—Amateur. (First query unsuitable; second incomprehensible. See indices.)—C. S. (Question much too wide. Procure some of the dealers' lists, and look up back volumes, Vol. XXVI., for instance.)—W. Butler. (Why do you allow your back numbers to be destroyed? A bichromate will do excellently, but you must use steel bars, and put them into a coil of insulated wire while current is passing. Quoting from Mr. Sprague's book, which is the best you can have, a short coil of stout covered wire should be made with an opening wide enough to take the bar. Then, while a powerful current is passing, the coil should be moved along the bar both ways several times, allowing the ends to enter half-way into the coil. Bring the coil back to the centre of the bar before stopping the current. The action is facilitated by slightly tapping the bar so as to produce vibration.)—Subscriber. (See previous answer.)—Pro Bono Publico. (Query 56079 will probably be answered in time. Perhaps this note will direct attention to it.)—W. W. W. (Recipes for staining billiard-balls have been given frequently under that head and also under Ivory Staining. The ivory must be first cleansed by washing well with soda solution or ammonia, and is then "quicked" by immersion for a minute in acid water, either nitric or hydrochloric; it is then transferred to the dye. For black use logwood decoction, and afterwards acetate of iron; for blue, a dilute solution of indigo, to which some potash has been added; for green, boil in a solution of verdigris in vinegar; for yellow, steep for 24 hours in strong solution of neutral chromate of potash, and then plunge into a boiling solution of sugar of lead; for red, first treat to a bath of tin salt, nitro-muriate of tin, and then plunge in a hot decoction of Brazil wood or cochineal, or both mixed; if a cherry red is required, place the ball dyed scarlet into a hot solution of potash; for brown, use weak solution of nitrate of silver. The simplest plan of all is to use aniline dyes. They fade, it is true; but they are cheap, and the balls can be restained as often as necessary with very little trouble.)—J. M. (See previous answer.)—Novice. (Unless very large quantities are required, it is cheaper to buy lacquers and varnishes. However, a good lacquer is made by putting a ¼lb. of turmeric, 3oz. of gamboge, 1lb. of sandarac, and ¼lb. of white shellac into two quarts of alcohol. When dissolved, add a gill of turpentine varnish and shake thoroughly.)—Desideratum. (Under those circumstances, why do you not procure a list of the tools sold by the dealers, and so learn what can be had? For putting mainsprings in watches, see Nos. 889, 892.)—Apprentice. (Query too wide. "Making" would include cutting up the wood. You must ask definite questions.)—Shalford. (For methods of treating eczema, see pp. 109, 114, 135, 156, 178, 201, Vol. XXXVII.)—Striving. (Certainly, they are of practical application, and are used for many purposes in calculation—by engineers and others.)—J. Jones. (We gave the address—J. and A. Churchill is sufficient; but their place of business is in New Burlington-street, W. We do not know the price. 2. The *Analyst* is published by Bailliere and Co., King William-street, Strand, price 6d.)—X. Y. Z. (Drop the tea and coffee and feed on porridge with milk. For the rest, be guided by a medical man who has an opportunity of seeing the child.)—Anxious. (No better places than the Surrey hills.)—Purifier. (The best thing is to destroy them by fire; but the only safe disinfectant is baking at a high temperature.)—Veritatis Quæstor. ("Better definition" of what? It cuts off superfluous light. See the indices.)—Coup d'Œil. (How can any one say whether your sight is likely to be permanently injured? You must wait and see. In future, be more careful in looking at the sun without a dark cap, or, at least, a piece of smoked or coloured glass.)—G. W. Rothwell. (For directions as to fitting up horizontal bar, see p. 218, No. 633, where there is an illustration. You must have a good ash bar 2¼in. thick, and it would be well to purchase one with a steel rod run through it.)—J. B. Hopkins, Telegraphist. (In type.)

**Every Workman** connected with the Building Trades requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence, at 332, Strand, London, W.C.

"THE BUILDING NEWS" is the Principal Journal representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is One Shilling for Twenty-four Words, and Sixpence for every Eight Words after

## NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a Pink Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

**Epps's Cocoa.**—Grateful and Comforting:—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—*Civil Service Gazette.*—Made simply with boiling water or milk, Sold only in packets, labelled—"JAMES EPPS and CO., Homœopathic Chemists London."—Also makers of Epps's Chocolate Essence

**Holloway's Ointment and Pills.**—For bad legs, gathered breasts, and scrofulous sores these are genuine specifics. The parts should be bathed with lukewarm water, and when the pores are thereby opened, the Ointment should be well rubbed in, at least twice a day.—The Pills eject all morbid matter from the system.—[ADVT.]

☞ A CHANCE OF A LIFETIME!

£10,000 IN PRESENTS TO SUBSCRIBERS!

This Offer Good till May 15th, 1885, Only.

GRAND CAPITAL PRIZE OF £1000 IN CASH.

The most magnificent offer ever made by a reliable publisher. THIS IS A CHANCE OF A LIFETIME FOR YOU. The proprietors of THE HOUSEHOLD JOURNAL have determined to outdo all former efforts of other publishers, by giving one of the following Grand Presents to every one who subscribes between NOW AND MAY 15th.

FOR ONLY TWO SHILLINGS Or Twenty-six Stamps, we will enter your name on our subscription books, and post pay to you regularly for Six Months our Illustrated Family Publication, THE HOUSEHOLD JOURNAL, and also send you a printed numbered receipt which will entitle you to one of the following Magnificent Presents:

LIST OF PRESENTS TO BE AWARDED OUR SUBSCRIBERS:

| | | | | | |
|---|---|---|---|---|---|
| 1 | Cash Gift | £1000 | 50 | Boys' Silver Watches, £2 each | £100 |
| 1 | Cash Gift | 500 | 50 | Ladies' Watches, £2 each | 100 |
| 1 | Cash Gift | 200 | 500 | Cash Presents, £1 each | 500 |
| 10 | Cash Gifts of £20 each | 200 | 500 | Beautiful Alarm Clocks | 200 |
| 20 | Cash Gifts of £10 each | 200 | 500 | Elegant Photograph Albums | 100 |
| 5 | Elegant Upright Pianos, £40 each | 200 | 500 | Floral Autograph Albums | 100 |
| 10 | Elegant Cabinet Organs, £20 each | 200 | 500 | Silver Fruit Knives | 100 |
| 10 | Beautiful Silver Dinner Sets, 7 pieces | 200 | 500 | Ladies' and Gents' Pocket Knives | 100 |
| 20 | Elegant Silk Dresses, £10 each | 200 | 500 | Sets Silver-plated Tea-spoons | 100 |
| 25 | Ladies' Solid Gold Watches, £4 each | 100 | 500 | Sets Table Forks | 100 |
| 25 | Gents' Solid Gold Watches, £8 each | 200 | 1000 | Oil Pictures | 200 |
| 25 | Ladies' or Gents' Diamond Rings | 200 | 1000 | Ladies' & Gents' Russia Pocket-books | 200 |

Together with 193,747 useful and valuable articles, worth from One to Two Shillings each, making a total of 200,000 valuable and useful articles to be given to our Subscribers on MAY 15th, 1885, so that each and every one who subscribes before that date will receive THE HOUSEHOLD JOURNAL six months and a beautiful Present besides. The Prizes will be awarded MAY 15th, 1885, full particulars of which will be given hereafter, and published in the Journal. Subscribers can have Presents forwarded to any part of the United Kingdom. Printed lists of the awards will be forwarded to all Subscribers, and also published in the JOURNAL immediately after the award.

THE HOUSEHOLD JOURNAL Is one of the most BEAUTIFUL and POPULAR MAGAZINES OF THE DAY. It contains Twenty Large Pages, and has an elegantly engraved, illustrated, and tinted Cover. It is replete with beautiful illustrations and choice literature. No expense is spared to make this publication one of the finest in the world.

REMEMBER, WE MAKE NO CHARGE for these presents. The Two Shillings is the regular subscription price for six months to the JOURNAL, and some one is sure to get a Grand Prize of £1,000. OUR PROFIT will come from our advertising patronage, which will be very large, at remunerative rates. We want 200,000 new subscribers before May 15th, and as we are now receiving daily as many as 3,000, we are sure to get the required number. There will be no postponement. Persons wishing to subscribe for a year will receive two receipts for Four Shillings or 52 stamps, entitling them to a year's subscription and two presents.

REMEMBER, we send the JOURNAL direct to your address, post paid, and enclose a numbered receipt for each six months' subscription in the first number you receive.

A FREE SUBSCRIPTION TO YOU.—If you will get five friends to join you, and send us Ten Shillings all at one time, we will send six subscriptions for six months and six numbered receipts, good for six presents. Send Twenty Shillings at one time, with the names of ten friends or acquaintances, and we will send twelve subscriptions and twelve numbered receipts, and so on, thus giving you an extra receipt and subscription for every five subscribers you send in, and each subscriber gets a numbered receipt, and will get one of the presents mentioned above. The JOURNAL is sent, post paid, direct to each subscriber's address you send us.

SEND MONEY by Registered Letter or P.O. Stamps should not be sent when P.O. can be obtained. SPECIMEN COPY, 4d.

Address—THE HOUSEHOLD JOURNAL, H. C. Edwards, Manager, 31, Bouverie St.,
FLEET STREET, LONDON, E.C.

CUT THIS OUT AND SHOW IT TO YOUR FRIENDS, NEIGHBOURS, AND ACQUAINTANCES, AND PERSUADE THEM TO JOIN YOU, AND THUS GET YOUR OWN SUBSCRIPTION AND RECEIPT FREE. AGENTS WANTED

## TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

6s. 6d. for Six Months and 11s. for Twelve Months, Post-free to any part of the United Kingdom. For the United States, 13s., or 3 dols. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.

Messrs. James W. Queen and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post-free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.

Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII., XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX. bound in cloth, 7s. each. Post free, 7s. 9d.
Vol. XL. ready shortly.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post-free from the office (except index numbers, which are 3d. each, or post-free 3½d.)

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XI. and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

## CHARGES FOR ADVERTISING.

| | s. | d. |
|---|---|---|
| Thirty Words | 2 | 6 |
| Every additional eight words | 0 | 6 |

Front Page Advertisements Five Shillings for the first 40 words, afterwards 9d. per line. Paragraph Advertisements One Shilling per line. No front page or paragraph advertisement inserted for less than Five Shillings. Reduced terms for series of more than 6 insertions may be ascertained on application to the Publisher.

ADVERTISEMENTS in EXCHANGE COLUMN—for

| | s. | d. |
|---|---|---|
| Twenty-four words | 0 | 3 |
| For every succeeding Eight words | 0 | 3 |

ADVERTISEMENTS in the SIXPENNY SALE COLUMN.

| | s. | d. |
|---|---|---|
| Sixteen words | 0 | 6 |
| For every succeeding Eight Words | 0 | 6 |

⁂ It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions; and in cases where the amount sent exceeds One Shilling, the publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O's.

The address is included as part of the advertisement, and charged for.

Advertisements must reach the office by 1 p.m. on Wednesday to insure insertion in the following Friday's number.

## OUR EXCHANGE COLUMN.

*The charge for Exchange Notices is 3d. for the first 24 words and 3d. for every succeeding 8 words.*

**Good Value Offered** (cash or instruments) for all kinds of sound or repairable Scientific Appliances.—Caplatzi, Science Depot, Chenies-street, near British Museum. Established 1862.

First-class **Patterns** offered in exchange for Electric Apparatus or anything useful.—Address, J. Fort, Pattern Maker, Cross-street, Gainsborough.

**Cast Steel**, 9-16, round and tough; mild weldable steel short bars 7-8 square, &c. Offers wanted.—Gilbert, Oxford-road, Sheffield.

Wanted, a good Collection of **Stamps**, also coins and Bric a Brac of every description, good exchange, approval required.—Address, Edward W. Drury, Hull.

**Perambulator Wheels**, with turned axles, ⅝ best Rubbers, 54 Wires, Brass Caps, complete, on approval, with pleasure. Exchange offers.—310, Bilston-road, Wolverhampton.

"**English Mechanic.**"—Back numbers given for Book on Artificial Hatching of Poultry.—J. Bond, Pahan, Londonderry.

**Lathe Wheel**, 28in., 5 speed, 50in. crank, turned, bored, treadle, complete, lathe standards, 7½ lathe head; 100 "E. M." Exchange.—Smith, Bilston-road, Wolverhampton.

**Telephones**, set for two stations, only wants slight connection to complete them; includes Blake's transmitters, bell receivers, induction coils, switches, mahogany cases, value £3; for useful exchange.—Williamson, 61, Derby-street, Bolton.

**Vertical Engine**, 16in. high, cylinder 4in. long, for Britannia Co.'s combined lathe and fretsaw.—Buckley, Old Vicarage, Batley.

**Cottage Piano**, Panel Front, nearly new, for tricycle and £10.—C. W. Searle, Sunninghill.

New **Launch Engine**, 3½in. bore, 4in. stroke, with propeller; also double cylinder engine, 3in. bore, 6in. stroke. Exchange bicycle or tricycle.—Chas. Bedwell, Whitstable.

24 **Microscopic Objects**, mounted on six ivory slides; also "Cary's Itinerary of Roads," date 1810. Offers, musical.—Teague, Roundwell-street, South Petherton, Ilminster.

Powerful **Induction Coil**, incased in mahogany, 1½in. spark, £3 10s. or offers in exchange.—H. Harris, Dalley-street, L.B., Manchester.

For **Microscope** Objective or Apparatus, will exchange Magic Lantern, and either accept or pay difference. One between 20s. and 50s. expected.—Write particulars, and for particulars to William James, 95, Victor-street, Walsall.

Wanted, 5in. backgeared **Latheheads**, or small Lathe. Exchange handsome Fern Case, 18-ct. Gold Ring or Pin, &c., or part cash.—F. Underwood, Beverley.

Wanted, Powerful **Medical Coil** for silk-covered wire terminals, double or single or battery terminals, platinum for contacts, quicksilver, &c., &c. State wants.—S. Beatty, Milford, near Derby.

**Bicycle**, 48in., "Gentleman's," Coventry make, cost £12 12s. Will exchange for anything of useful nature.—Pearce, Pellatt-road, Dulwich

**Stationery Cabinet**, with folding doors, date box, drawers, slides, and divisions, made of handsome burr walnut, and nearly new, cost £3 15s. Useful offers.—Pearce, Pellatt road, Dulwich.

**Booth's Mitring Machine**, Photographic Apparatus, Lenses and Sundries, in exchange for lathe heads, electromotor, dynamo, or electric bells.—Read, 156, Wyndham-road, Camberwell, S.E.

"**English Mechanic**, from commencement, 40 Vols., 19 bound, all in perfect order. No reasonable offer refused, owner going abroad. Will exchange for central-fire gun.—Major Allen, Gosport, Hants.

Wanted, in exchange for a fine-toned **Organ** Accordian, nearly new, value £3 10s, several well-bred Rabbits, tame Hares, or Ducks.—G. F. H., 20, Lime Grove, Handsworth, Birmingham.

48in. **Bicycle**, black enamelled, hubs bright, cone bearings back wheel, lamp, bell, satchell, and contents, complete. Good saddle.—18, Mount-street, Walsall.

Splendid set of spring **Bow Compasses**, in satin case, bow, pencil, pen, and dividers. Good violin. Offers.—18, Mount-street, Walsall.

First-class tenor slide **Trombone**, new, celebrated maker. Wanted in exchange four-valved Euphonium, or Double Bass (string).—John Carr, Poste Restante, Cardiff.

Vertical **Engine**. with brass cylinder, 1⅛in. bore, in good working order. Will exchange for small Lathe, or offers. —J. Leyland, Park-lane, near Wigan.

**Lathe Heads**, 6in. centre, flywheel, face plates, handrest, wood bed, crank shaft, &c. Will exchange for Bicycle; if out of repair no objection.—W. Powell, 13, Blaina-road, Abertillery, Mon.

Silver-plated **Tea Service**, all new; coffee pot, teapot, cream jug, basin, and sugar bowl. Exchange for Bicycle.—W. Powell, 13, Blaina-road, Abertillery, Mon.

**Photographic Apparatus**, various, for 5 inch Slide-rest, or bound back volumes of English Mechanic.—Day, 56, Driffield-road, Old Ford, London.

**Speculum**, silver-on-glass, 9 inches diameter, 6 feet 2½ focus.—Day, 56, Driffield-road, Old Ford, London.

**Sewing Machine**, Clegg and Blacklock. Exchange for bound Vols. of English Mechanic.—Day, 56, Driffield-road, Old Ford, London.

**Bird Cages**.—About 24 various, breeding, &c., for back Vols. of English Mechanic, or 5in. Slide-rest.—Day, 56, Driffield-road, Old Ford, London.

Wanted, quarter or half-plate **Camera**, with good lens, state price, &c. Exchange steam-pressure Gauge, 1in. dia., 60lb.—G., 204, Devonshire-street, London, E.

Wanted, two good **Telephone Receivers**, or Telegraph Instruments. Exchange compact stereoscopic camera, two pairs of lenses, and six double dark slides.—Dr. Browne, Thurning, Oundle.

## THE SIXPENNY SALE COLUMN.

***Advertisements are inserted in this column at the rate of 6d. for the first 16 words, and 6d. for every succeeding 8 words.***

**Plating**. — Every description of Gilding, Silver Plating, Oxidising, and Bronzing, executed with very best finish. Speciality in nickel-plating. Special quotations on application. Send one stamp for price list. Small jobs attended to per return post.—Morris Cohen, 132, Kirkgate, Leeds.

**Fretwork**.—Illustrated Catalogue of every requisite and 400 miniature designs, 4 stamps.—Harger Bros., Settle, Yorks.

Orguinette **Music**, all the latest tunes. Price 1½d. per foot. Organina music. Orguinette, 30s. Lists free.—J. E. Wood, 1 City-road, Finsbury-square, London.

**Violins**, selected Bavarian and French, 9s. 6d. and 15s. Half usual prices. Carriage paid on approval.—Patten and Co., Importers, 127, Essex-road, London, N.

**Trouser Lengths**, 5s. each. Cheap Cloth for Ladies' Dresses. Mantles, Boys' Suits.—Hewitt, 27, Winfield Mount, Leeds. Patterns free.

**Electric Depot**, 10, Deansgate, Manchester.—Electric Breast Pins, 25s. Electric Bells, 4s. Induction Coils, 8s.—Millar, Proprietor.

Write for Hindle's **List** of Electrical Apparatus, free; all parts for amateur construction.—Irwell Vale, Helmshore.

**Motor Castings**, materials for Electric Bells, Batteries, Galvanometers, Intensity Coils, Microphones.—King, Mendham, and Co., Bristol.

**Insulated Wire Table**, showing size, weight, resistance per foot, feet per ohm, &c., price 3d.—King, Mendham, and Co., Bristol.

**Standard Ohm**, in box, copper poles, guaranteed correct to ten thousandth of ohm, 21s.—King, Mendham, and Co., Bristol.

**Wimshurst Influence Machine**.—Sole Manufacturers of Improved Pattern. Numerous testimonials as to thorough efficiency.—King, Mendham, and Co., Bristol.

**Galvanometer Cards**, improved for tangent and ordinary combined, 2½in., 8d.; 4in., 10d.; 6in., 1s.; post free.—As Above.

Write for **King, Mendham, and Co.'s** large new and reduced Price List, post free 4 stamps.

**Dark Slides**.—20ft. Grooving for making above, 5s. —Marcus Warne and Co., 39, Legh-street, Warrington.

100 **Foreign Stamps**, including Brunswick, Ceylon Tasmania, Egypt, Greece, Luxemburg, free 7d.—Hely, Foley-street, London.

Patent Spiral Grip **Letter Racks**. "An invaluable invention." Parcels post, 1s. 3d.—Iles, Highgate-street, Birmingham.

**Microscopic Slides**, a valuable collection, 7s. dozen Two samples, 15d. free.—Tylar, 33, Geach-street, Birmingham.

"**Lantern Manipulation**," 3d. post, gives instructions, management, and making lime and oil lights.—Pumphrey Stanhope-street, Birmingham.

10,000 **Lantern Photographs**, 6d. plain; 1s coloured. List, 140 pages, facsimile illustrations, 100 sets, 6d. post.

**Pocket Tripod**, patent, for professionals and amateur photographers, cyclists. Particulars, illustrations, and testimonials to be had on approval.—A. Pumphrey, Stanhope-street, Birmingham.

**Lantern Readings** to 100 sets slides, with facsimile illustrations, 80 sets for 2s. 3d.—Pumphrey, Stanhope-street Birmingham.

**Mica**, otherwise Talc.—RICHARD BAKER & Co., 9 Mincing-lane, London.

**Marking-ink Pencil**; satisfactory or money returned; 7 stamps.—James Parkinson, 45, Sankey-street, Warrington.

**Electric Bell**, Battery, Push, 20yds. Wire, carriage free 9s. 6d.—Franklin.

Portable **Bell**, Battery, Push, 20yds. Wire, in stained and polished pine case, carriage free 10s. 6d.—Franklin.

**Wholesale Bell and Battery Maker**, Indicators, Induction Coils, Carbons, Terminals, Wires, &c.—Franklin, Volta Works, 41, Sherman-road, Reading.

**Printing Presses** from 10s., complete. Instructions to amateur printers, just published, post free 1½d.—Adams, Daventry.

**Photo Apparatus**, half-plate, Ross lens, a bargain. —G. V. B., 12, Hereford Gardens, W.

Cox-Walker's **Incandescent Lamp-Holder** new patent, highly approved, post free, 1s. 6d. stamps.—Harrison, Cox-Walker, and Co., Darlington.

**Catapults**, 7d., 1s., 1s. 2d.; elastic 2d., 3d. foot; square 1d. to 4d. yard.—Moody Bell, Cheltenham.

**Elastic Stockings** for Varicose Veins.—W. SMITH and Sons, 37, Breck-road, Liverpool. None made in London.

**Cat Gut**.—Gut Hooks and Eyes for lathes and machinery.—James Bellaers, Regent-street, Leicester.

**Bellaers' Gas Stoves**, 1s. 3d., 2s. 3d., 3s. 3s., for boiling. Breakfast Stoves, 8s., 11s., 14s. 6d. Send for lists.

**Edward W. Drury**, Hull, Glass Bottle and Cork Manufacturer, Importer of Chemicals, Caramel, Glucoses, Tinned Wire.

Edco six-cell **Battery**, twelve new porous pots, new zincs; will drive sewing machine, motor, or three 5 c.-p. lamps 120 hours without recharging for 8s. inclusive; last price, £4 10s. Cost £7 10s.—Address, C. R. Heap, 62, Coleman-street, E.C.

Celebrated Kerry **Ferns**, 12 varieties, including rare filmy, 1s. 6d. free.—FitzPest, Rathanny, Tralee, Kerry

**Tricycle Wheels**, Bicycle Wheels, and Fittings Wonderfully cheap. Also for safety Bicycles.—W. Gwinnett and Co., Wolverhampton.

**Gas Bath Heater**, Phillips' patent, with towel warmer.—Baker, 9, Mincing-lane, London.

Model **Steam Engines** made or repaired. Separate parts fitted up, boilers made to order.—Lucas and Davies, 21, Charles-street, Hatton-garden, London.

**Lathes**, Lathes. Cheapest and best. List, 2 stamps Nothing equal at price.—Robinson, Somerset-road, Sheffield.

The **Telegraph Tricycles**, T-framed, front steering, ball bearings, scientifically constructed. List free.—Norton, Crockherbtown, Cardiff.

**Hematite** for Jewellers.—RICHARD BAKER and Co., 9, Mincing-lane, London.

**Brazilian Peebles** and Crystals.—RICHARD BAKER and Co., 9, Mincing-lane, London.

**Rutil**.—RICHARD BAKER and Co., 9, Mincing-lane, London.

**The Perfect Pea Trainers** (Patented). Send for price list to Thomson's, Seed Merchants, 20, High-street, Birmingham.

**Type Writer**, Remington, capitals only.—Specimens and price from Ratcliff, 20, Cardoza-road, London, N.

Cotton-covered **Wire**, d.c., 10 to 18, at 1s. 6d.; 20, 22, 24, 26, at 1s. 9d., 2s., 2s. 3d., and 2s. 6d. lb. Bell Wire (cotton and rubber covered), 1d. per yard.—Darvill, 8, Brent View-road, The Hyde, London, N.W.

Model **Engine Castings**. Best and Cheapest. See list (stamp) and compare.—Wood, Dalley-street, Broughton, Manchester.

**Battery**, bichromate, highest electrical efficiency, Contains 10 per cent. more chromic acid than potash bichromate. Lee's new double Bichrome. Soluble in own weight water. No crystals formed. Recommended in "E.M." week before last. (Reply 55916). 7d. 1lb., 7lb. sample parcels. 6½d. lb. in 56lb. lots.—R. A. Lee.

**Dynamo Machine**, 20-light, continuous working, patent disc armature, low speed, requires ½-h. to drive, £15.—R. A. Lee.

**Electro-Motors**, Batteries, Dynamos. For Lee's other electrical specialities see advertisements week before last.—R. A. Lee, 76, High Holborn, London.

**New Time**.—Alter your Clocks and Watches. Twelve Sets of Figures, with instructions, 6d.—Wheeler, Preston.

**Water Motors**, for sewing machines, organettes, window advertisements, 32s., 42s. List one stamp.—Wheeler.

**Fan Castings**.—Improved Registered Designs; sets 5in., 3s.; 6in., 4s.; 8in., 5s. Drawings, 4d.—Wheeler, Engineer.

**Water Motors**.—Complete one horse-power, £9. Half, £8. Quarter, £4. Eighth, £3.—Thomas Wheeler, Preston.

**Micro-crystallisations**.—A few good specimens for polarised light, 1s. 1d. post free.—H. Harris, Dalley-street, L.B., Manchester.

**Engineers** and Millwrights in general, also Inventors' Plans and Ideas worked out with despatch. Estimates and consultation free.—Mr. Dunn, 222a, City-road, London, E.C.

**Lathe**, 2½in. centres, faceplate, and rests. 25s., carriage free.—Hancock, 81, Peter's-road, St Albans.

**Bell Wire**, double-cotton covered and paraffined, 110 yards, 3s. 2d, complete. List free.—Maw.

**Magnesium Ribbon**, 4 yards 1s., post free.—MAW, 8, Claylands-road, London, S.W.

First-class Astronomical **Telescope**, by Solomons and Cooke; equatorial, by Grubb, Dublin; 3½in. o.g., action and condition perfect.—Apply at once, D. Milligan, 21, Spencer-road, New Wandsworth, London.

What price and weight per foot 80ft. **Chain** up to guaranteed strain 8 tons.—C. B. A. Long, Melford, Suffolk.

**Polish** for Nickel, Brass, Silver, &c.; brings up the article equal to new. Surpasses all other polishes. Sample box, post free, 4d.; larger, six times as much, 1s. 2d.—F. Smith, 6, Westborough, Scarborough.

**Thought Reading**.—For 8 stamps will forward instructions which will teach anyone to become a thorough thought reader.—Below.

**Mesmerism**.—All can mesmerise. Instructions 8 stamps, never fails.—Below.

**Clairvoyance**, or Second-Sight.—Instructions 8 stamps. All three, 13 stamps.—G. Marquis, Allhallowgate, Ripon.

**Lathe**, back-geared, 6in. to 8in. centre, 7ft. bed, with traversing screw, slide-rest, and saddle, back centre, face plate, 11 change wheels, and overhead motion, £13.—79, Dudley-road, West Bromwich.

½ H.-P. Vertical **Steam Engine**, cheap, 50s. Stamp. —H. Calderbank, Vale-road, Bowdon, Cheshire.

**Electric Bells**, double, silk coils, mahogany case, &c., 4s. each, free.—Sledge, Wyatt, and Co., Clapham.

**Pendulum Indicators**, 3-hole, 15s.; 6-hole, 22s.; over 6, 3s. 6d. per hole.—Sledge, Wyatt, and Co.

**Hand Dynamos**, £2 10s. each, work small lamps, &c.—Sledge, Wyatt, and Co., 95, Wirtemburg-street, Clapham.

**Sounder and Key**, 30s.; single-needle instrument, 30s. (for learners).—Sledge, Wyatt, and Co., Clapham.

**Galvanometers**, highly finished, brass case, silvered divided dial, 1½in. diam., 20s. each.—Sledge, Wyatt and Co.

**Model Boilers** from 7s. 6d. each. Send stamp for list to J. N. M., 41, Cross-roads, Upper Wortley, near Leeds.

50in. Emperor **Bicycle**, suitable for learner, price £1. —B. Davis, 23, Brunswick-street, Ramsgate, Kent.

**Gas Engines**, simple, cheap and reliable, 1 M.-P. to 1 H.-P.—W. and J. H. Hill, York.

Steel **Tricycle**, specially designed for mechanical power, cost £35. What offers? Must sell.—W. H., 46, Newbro-street, York.

**Induction Coil**, 1in. spark, discharging pillars, commutator, and condenser, ebonite reel ends, on ornamental mahogany stand, price 50s.—Williamson, 61, Derby-street, Bolton.

**Cyanotype Paper**, 4d. per sheet. Specimen Print free.—Humphries, 5, Esher Villas, Shadwell-road, Holloway, London.

**Hull** of Steam Launch, 33ft. by 6ft. 6in., by Forrestts, of London, capital sea boat, decked, cabin aft, propeller, shaft, mast, spars, sails, anchors, chain, &c., price £60.—Apply, Robt. Jones, Shipbuilder, Rhyl.

**Launch Engines**, suitable for 25ft., 35ft., and 50ft. launches; boilers, propellers, and fittings complete.—S. Smith, 11, West-street, Soho, W.C.

Locomotive **Photographs**, job lot, cartes, six, all different, free 1s.—W. Algar, Stonard-road, Winchmore-hill, N.

**David Copperfield**—Lantern Photograph Blunderstone Church, 1s. P.O.—Geo. Waller, 2, Middlegate-street, Great Yarmouth.

**Launch Engines**, new, some second-hand, cheap. Please state requirements.—John Middleton, 16, Hope-street Glasgow.

**Lathe**, 4in. centres, self-acting, screw-cutting, new, a bargain.—John Middleton, 16, Hope-street, Glasgow.

**Cassell's Illustrated Travels**, Nos. 1 to 19, published at 2s. each, price £1.—J. H. G., 100, West-road, West Ham Park, E.

"**English Mechanics**," Vols. XXVI.—XXXVII., inclusive, ten newly handsomely bound, price £2.—27, Mount Pleasant-road, Lewisham.

Bichromate **Battery Cells** (flint glass) Bottle form, quart, 3s. 6d., complete 10s. Other sizes, larger or smaller much below list prices.—Wm. Whitham, Parker-street, Barnsley

24 **Microscopic Slides**, in box, very cheap. List sent for stamp.—Well, Dalmain-road, Forest Hill.

Silver-on-Glass **Mirror**, 7ft. focus, beautiful definition, flat to match, mounted.—S. Cooper, Charminster, Dorchester.

**Engine and Boiler** combined, 2-horse, £17. Boiler, vertical, 1-horse, £6.—79, Dudley-road, West Bromwich.

Powerful **Horizontal Engine**, cylinder 2in. by 1in., price £2.—Particulars and photograph from F. D., Brooklands, Dorchester.

**Lenses**, to form best quality of Panoratic Terrestrial Eyepiece, post free, 5s. 6d.; ditto for astro. eyepiece, free, 2s. 6d. —Wm. Nicholl, Roslea, Clones.

**Binocular Telescope**, 50s. Large Field Glass, by Steward, 35s. Elegant pearl Opera, 15s.—99, City-road.

Valuable Photographic **Apparatus**, by order of executors, Ross and Dallmeyer Cameras and Lenses.—99, City-road.

Powell and Lealand **Microscope**, 2 eyepieces, 3 objectives, accessories, glazed cabinet, only £7.—99, City-road.

Astronomical **Telescope**, 3 inch achromatic, three eyepieces, garden-stand, and case complete. Price £9 10s.—K., 33, London-road, Maldon.

**Photographs**, Scottish Scenery, cabinet size, extraordinary value, 4d. each.—Address, Photo, 182, Trongate, Glasgow.

**Gelatines** for tracing Magic Lantern Slides, 3¼ size, 4½d. dozen.—Address, Photo, 182, Trongate, Glasgow.

**Incandescent Carbon Lamps**, low resistance, 3s. each; Fairy Lamps, 3s. 6d.; Platinum Lamps, 1s. 3d., post free.—Todd, 14, Wentworth-road, Manor Park, Essex.

**Incandescent Lamp Holders**, new pattern, best in the trade, 12s. dozen; sample, post free, 1s. 3d.—Todd, as above.

**Formulas Worked Out** for winding Dynamos from 10 c.-p. to 500 c.-p., 8 stamps each.—H. Jones.

**Dynamo Castings**, 100 c.-p., cog armature, Gramme fields, 9s. a set. Motors with patent armature, 3s. a set. —H. Jones.

**Dynamos**, patent improvements, No. 2,192. 70 c.-p. machines, £5. 32 volts, 7 ampères.—H. Jones.

**Dynamos**, best small machines in the trade, and cheapest double-covered Wires to 20 gauge, 1s. 8d. 1b.—H. Jones.

**Dynamos** for Home Lighting.—5 lights, or arc of 500 c.-p. Price £6 10s., approval. Warranted.

**Dynamo Castings**, with laminated armatures, 8 c.-p., 5s.; 16, 5s. 6d.; 20, 6s. 6d.; 30, 7s. each.—H. Jones.

**Dynamo**, laminated armatures, no heating, ventilating; 70 c.-p., 16s. a set; finished, £5. Warranted.—H. Jones.

**Dynamo Machines Repaired**. Motors, with wire, 5s. 6d.—H. Jones, 48, High-street, Lambeth, S.E.

**Lathe Heads**, Slide-rests, Beds, Standards, Flywheels, Cranks, Chucks, and Accessories, rough or finished. See list.—W. R. Smelt.

**Machine Work Done** on customers' materials, best workmanship, at moderate prices. Estimates free. Send particulars.—W. R. Smelt.

**Turning**, Boring, Planing, Screw-cutting, Forgings, Patterns, &c. No charge for estimates or advice.—W. R. Smelt.

6in. centre single-speed **Lathe**, V and flat bed, slide-rest, Chucks, &c., equal to new, £13.—W. R. Smelt.

**Enlarged and Revised Price List**, 1 stamp.—W. R. Smelt, Engineer and Tool Maker, 7, Goldsmith's-row, Gough-square, E.C.

The English Mechanic
AND WORLD OF SCIENCE AND ART.
*FRIDAY, APRIL* 17, 1885.

## WATCH AND CLOCK MAKING.*

THERE cannot be much doubt of the decadence of the clock and watchmaking trade in this country during the last twenty years; but it may be questioned whether that decadence is altogether due to the entire absence of any system of technical education, although the want of some means of technically training the rising generation of mechanics and artisans must exercise a potent effect on the future of any trade. Mr. Glasgow would probably agree with us that for the very highest class of work Clerkenwell still retains its place, and it is mainly because the trade has been too conservative—too much attached to old practices—that other countries have taken the lead in the production of the commoner kinds of watches, while the manufacture of cheap clocks seems never to have formed a portion of the trade of this country. A change has, however, been brought about within recent years, and there is rising up a generation of watchmakers who, while skilled in all the necessary manipulations, will possess that technological knowledge of the subject which should place them in the front rank of horologists. So many books have been published on watch and clock making that Mr. Glasgow felt some hesitation in accepting the task of writing this work, which forms one of the "Manuals of Technology" issued by Messrs. Cassell; but his desire to promote the educational movement now going on overcame his hesitation, and we have as the result a textbook which, in a moderate space, contains a vast amount of theoretical and practical instruction. Commencing with a chapter on Time Measures, the author briefly but very clearly points out the difference between a sidereal and a solar day, explains the use of the transit instrument, quoting Latimer Clark's instructions for applying it in the determination of time, and Ferguson's directions for tracing a meridian, giving also a short account of Bloxam's dipleidoscope. The historical notes on sundials, clepsydræ, sand glasses, and clocks are necessarily brief, but Mr. Glasgow has contrived to give an epitome in a few paragraphs. Referring to the English clock trade, he tells us that with the exception of turret clocks, it never has attained to any importance, while of late years the manufacture of house clocks may be said to have almost entirely left us. The French took the "drawing-room clock" trade out of our hands, their taste and artistic education having enabled them to produce goods which have entirely superseded the English clocks of that class. With the exception of turret clocks, first-rate regulators and quarter clocks, and a few eight-day and school clocks, the manufacture is practically unknown in this country, because, as Mr. Glasgow puts it, English makers used no efforts to supply obvious public requirements either in the way of cheapness or elegance. Even the eight-day kitchen clock is being hard pressed by the cheaper importations from Holland, Belgium, Germany, and America. The quarter clock has, however, never been rivalled by any foreign production, although a number of imitation quarter and other old English clocks have been imported from France. The imitation article can, however, be readily detected, it seems, by noticing the distance apart of the winding squares, for in the English clock the movement corresponds in size to the dimensions of the case, whereas in the foreign imitation the movement bears but a small proportion to the large and showy exterior, and the winding squares are consequently comparatively close to one another. Regulators and astronomical clocks are not in sufficient demand to become a wholesale manufacture, and in that line we have actually a small export trade, for with the exception of some inferior productions from Austria and Germany, there are no foreign makers. The French have nearly the whole of the trade in marble, gilt, and carriage clocks, while the Americans have beaten the Germans out of the field with their cheap kitchen and bedroom timepieces and alarums. Mr. Glasgow devotes more space to the history of the watch, which has been gradually developed since the invention of the mainspring by Peter Hele, of Nuremberg, circa 1500. Cheap watches are made at Liverpool, Coventry, and Birmingham, and factories have been established at the two latter towns, to compete with the large number of American factory-made watches. These, it must be confessed, are so good in their way that they are serious rivals of the cheaper makes of English watch, and are preferred to those manufactured in Switzerland. The attention of the English watchmakers has been devoted rather to improvement in the quality of their goods, than to cheapness of production, and it is a question whether the introduction of the factory system and the wholesale adoption of machinery would altogether benefit the trade here. As Mr. Glasgow says, "English watches have always commanded their price in the markets of the world, and the good name they have ever borne has led to their imitation by foreign producers, both by the forgery of English makers' names, and of the English hall marks in the cases." It is advisable to keep up the high standard of excellence achieved by our Clerkenwell horologists; and if we are to produce a more marketable article, proceed in the right direction by "organising our system of manufacture, by altering and improving the plan of our movement (not by the elimination of the fusee, but by, amongst other things, the total abolition of the full plate in favour of three-quarter and half-plate movements), and by imparting more intelligence and education among our workmen." There can be no doubt about the advisability of organising the manufacture, and giving the best technical education to apprentices; but we imagine that Mr. Glasgow will not find everybody agreeing with him as to the best plan of movement, and the divergences of opinion will increase as watchmakers become more and more technically educated. The parts of a watch known as the movement, that is the frame, fusee, barrel, wheels, and pinions, have been made at Prescot in Lancashire for many years, whence they are sent to the three places above mentioned, though the bulk of the trade is done with London and Coventry. The choice of Prescot as the seat of this trade came about in this way: When watchmaking for export became an important business in Liverpool, it was soon evident that it would be economy to have the rougher parts made in villages by less skilled workmen, and finish the watch in the town. Accordingly Prescot, being near Liverpool, and having a reputation for making the best files and other tools, was chosen; and there, thanks to the energy of Wycherley, movement-making has been firmly established, for he erected a factory, put down several costly machines, by which ultimately he was able to supply the trade with movements in eight standard sizes, at a very low price. His successor followed the lead, and at Prescot they now turn out movements with the keyless work attached, which are superior in quality to the Swiss, and compare favourably with them in price. This fact, that the movements are made by those who are not watchmakers, accounts for the difficulty experienced in introducing changes; for the Prescot manufacturers, puzzled by the conflicting opinions and requirements of the watchmakers, have failed to make any improvements in the design of the movement, and a bad model for a cheap watch was allowed to keep the field until the trade woke up to the fact that a large portion of their business was leaving them. The factories established at Coventry and Birmingham, of course, make the movement on the premises, and may ultimately work a revolution in the trade. Mr. Glasgow has nothing but condemnation for the "full plate" movement found in the bulk of English watches; for, in the first place, it makes a thick and clumsy-looking watch, in which the hands cannot be set without opening the cover, and as the square of the cannon pinion must project above the minute hand, there must be more room between the dial and the glass than is wanted for the clearance of the hands. There is an arrangement for setting the full-plate watch from the back, but Mr. Glasgow says it is so bad it is not worth describing. If its external defects are so serious, its internal arrangements are positively bad, and yet "it is still considered to be *the* English watch, nearly all the Coventry watches being of that construction." The plates for the movement are stamped out in Birmingham, whence some of the Swiss manufacturers obtain their supplies, and labour-saving machines are used wherever practicable and economical. In the case of screws it would seem that a machine is not wanted, for Mr. Glasgow tells us he saw a man making them in an ordinary hand-throw at Wycherley's factory. So expert was this workman that "he turned down the body of the screw, tapped it, rounded and burnished the end, tapered the head, and cut it off in 15 seconds. These were bar screws—pillar screws took a little longer, he made three of those a minute, repeating this operation several times while I watched him, and he appeared to be in no hurry over his work." Here and there throughout the volume the author loses no opportunity of expressing his opinion about the "full plate," and it would be fitting for some of those who defend it to answer Mr. Glasgow's objections. The succeeding chapters to that on the movement are necessarily of a technical character, but in that on wheels and pinions, the theoretical and practical information is sufficient for the student, while in that on trains, the reasons why the Nos. 18,000, 16,200, and 14,400 are adopted in different makes, are clearly explained. In the chapter on the fusee and mainspring there is matter to interest any mechanic, whether he has a watch or not; and in that on chronometer and watchmaking, there are many points which should be carefully studied by the apprentice or pupil, for Mr. Glasgow does not believe in the old apprenticeship system. Here is a point, for instance, where the author says, "if watch finishers, or even examiners, had thoroughly understood the uses of the adjusting rod, and freely used it, half the faults that have been found with the fusee watch would have been avoided." Amongst those who buy many are attracted by the statement that the watch is jewelled in such or such a number of holes. On that point Mr. Glasgow says: "I have heard men argue that the third and fourth wheel holes of a watch would be better to be of good brass than to be jewelled. I am sure there are thousands of English watches that would have gone longer and cost less to repair, if they had been jewelled in a few more holes. The Swiss, on the other hand, jewel their very worst watches in as many holes as possible, and do it so badly, that brass holes would in many cases be preferable." Mr. Glasgow writes at considerable length on escapements, the balance spring, and the compensation balance, and he also gives some interesting information on keyless watches with the fusee—the stem-winding arrangement, which promises to become fashionable, being much more easily applied to the going-barrel watch. Keyless watches were, it seems, first made by Peter Caron, of Paris, in 1752; but the first invention of the kind which was adopted by the trade to any extent was that of Prest, of Chigwell, who in 1820 took out a patent for winding a watch by the pendant knob. Since then, and more especially in recent years, several forms of keyless work have been devised; but, as Mr. Glasgow says, if many watches are to be made on this principle, it would be better for the trade to adopt one form; and keep to it. The keyless work is, however, nearly all done in Lancashire by the movement makers, thus for the ordinary run of watches securing the best model, great uniformity, and cheapness of production. Pendulums and compensation pendulums for standard clocks and regulators receive a due amount of attention from Mr. Glasgow, who says that the zinc and steel compensation pendulum is probably more suitable than any other for all very large clocks, as it is cheap and sufficiently accurate. That is perhaps faint praise, for, according to Sir G. B. Airy, the zinc and steel pendulum applied to the Greenwich sidereal clock answered quite as well as a mercurial pendulum. Of dead-beat and gravity escapements, Mr. Glasgow says that Graham's device is the one generally applied to all the better clocks with seconds pendulums, for which it is best adapted; but it is not so suitable for smaller clocks with shorter pendulums, or where springs are used for the driving power. The gravity escapement of Sir E. Beckett is the best for all very large clocks where the hands are exposed to the action of wind, as it admits the application of great driving power without sensibly affecting the escapement by increased resistance to unlocking. The performances of the Westminster clock effected a revolution in the turret-clock trade of this country, and produced a revival of an industry which was rapidly declining. There seems no good reason why clocks should not be made as cheaply here as anywhere, remembering that quality is the test of cheapness. Says Mr. Glasgow; "If a factory or factories could be established here with sufficient capital and machinery, there is no doubt we could make clocks cheap enough to compete with all comers. I believe that at present only the movements of the American clocks are imported, the cases and fittings being made more cheaply here; and these movements are poor things." We have, however, reached the limits of our space; and in taking leave of Mr. Glasgow's manual, we must say that it is just what a technological handbook should be, for it explains the principles and the practices side by side, as it were, and gives sufficient details to enable the student to thoroughly comprehend the subject.

---

* Watch and Clock Making. By David Glasgow, London, Paris, New York, and Melbourne: Cassell and Co.

## THE ELECTRICAL EXHIBITION AT THE PARIS OBSERVATORY.

THE Société Internationale des Electriciens under the presidency of M. Berger, has held a very interesting exhibition in the galleries of the Paris Observatory, which Contre-Amiral Mouchez kindly left at the disposal of the electricians for their attractive displays. Our readers will not expect to have anything altogether new since 1881, and the Electrical Congress. However, even to the superficial observer, this exhibition, though on a much smaller scale than that of 1881, shows a striking progress in the fixity of the electric light.

The necessary power was supplied by steam engines, making a total of 200 h.p. About 500 incandescent lamps and 50 regulators were distributed in the building.

M. Gerard exhibits three dynamos, absorbing each 3½ h.p. and giving each a current of 100 volts and 20 ampères.

The first of these dynamos lights 32 incandescent lamps of 25 candles each. The second 21 lamps of 50 candles, and the third lights four lustres of 21 lamps of 25 candles each. M. Gerard also exhibits a smaller dynamo of ½ h.p. lighting 6 lamps of 12 candles, or 4 lamps of 25 candles, or 3 of 50. M. Gerard's 12-candle lamps require from 16 to 18 volts and 1½ ampère; the 25-candle lamps require 25 volts and 2 ampères; the 50-candle lamps 30 volts and 2½ amperes.

Among the other incandescent lamps we notice those of Edison, Swan, Maxim, Cruto, Aboilard; among the regulators Breguet's, Cance's, and Siemens'.

The Société d'Electricité exhibits a Gramme machine absorbing 8 h.p., which works an endless saw, a printing press, a ventilator, a motor for turning the great dome of the Observatory and lights a 500 Carcel regulator in the said dome. The Hotel de Ville of Paris, and the Ecole Centrale are furnished with ventilators worked by Gramme machines.

One of Colonel Mangin's projectors sends forth a brilliant cone of light from the terrace of the Observatory, casting long and dark shadows, which puzzle the foot passengers, and cause a stumble now and then. The light from this projector was powerful enough to enable me to photograph the fountains of the Luxembourg with its dark green statues. The distance is about 450 yards from the Observatory.

Experiments and auditions, with the Ochorowicz loud-speaking telephone have been very successfully conducted at this exhibition. Not only cornet playing and singing were transmitted, but also the accordion, and even the violin, were well heard by a whole room of visitors. This telephone is described on page 97 of the English Mechanic. Even without the microphone, Dr. Ochorowicz's telephone gives the loudest transmission of speech that I ever heard. For the auditions at the Observatory, the loud-speaking telephone was used in connection with Dr. Ochorowicz's thermo-microphone.

M. Estienne exhibited a new form of Morse telegraph, in which the dots and dashes are replaced by short and long vertical strokes. This result is obtained by two pens which can be made to press against the strip of paper by means of an electro-magnet and suitable levers. The inversion of the current is obtained by a transmitter like that of the single-needle-telegraph. The telegrams are much more easily read with this system than with the ordinary one. It is easily seen that by pressing longer on each key of the transmitter, we may also obtain thick signals, so that we may have four different signals with M. Estienne's instrument.

M. Carpentier's exhibition is almost wholly devoted to electrical measures. We notice the standard ohm as fixed by the Congress of Electricians. M. Lippmann's new and ingenious ampère-meter is shown by Breguet. In this instrument a tube containing mercury is fixed at right angles to the poles of a magnet. The current to be measured passes through the mercury, which is put in motion according to the laws of electricity; the metal rises or falls in a graduated tube, and thus indicates its intensity.

Two railway companies have sent specimens of their electrical appliances.

Among the various apparatus exhibited by the Chemin de Fer du Nord, let us notice the "crocodile." It consists of a slanting piece of wood covered with brass which is placed in the middle of the two rails. A metallic brush is fixed underneath the locomotive so as to brush over the "crocodile" when the train passes at that spot. Now if we connect one pole of a battery to the crocodile and another to the rail, it is clear that when the train passes, the circuit will be closed, and may be made to ring a bell at a distance and announce the train. M. Sartiaux has improved this contrivance by putting two parallel brass strips to the crocodile instead of one. Two separate circuits can thus be closed by the locomotive, and they are thus utilised. The crocodile is placed about 200 yards before the disc. If the line is open (*i.e.*, not blocked by the disc) the train goes by, brushes the two strips of the crocodile and announces itself at the next signal-box. The signal-man, of course, immediately blocks the line by turning the red disc at right angles to the rails. Now, suppose another train follows and the driver does not see the disc on account of fog, for instance, not only the train will announce itself as the first one did, but moreover, it will be automatically stopped, for when the disc blocks the line, a second battery sends a current in the second brass strip of the crocodile and passes through an electro-magnet in the machine, which puts the air-brake on. All accidents are thus avoided.

In the exhibits of Paris-Lyons Company, the train announces itself by running over a pedal placed on one side of the rail; this overturns an iron cylinder containing mercury which closes a bell circuit. In M. Chaperon's device the trepidation of the train causes a ball carried by a horizontal spring to tremble. This breaks a current which passes continuously when the ball is horizontal (for it then rests against a vertical spring which closes the circuit) and rings a bell by interrupting the current.

This exhibition is certainly a very great success; but, unfortunately no means have been taken to prevent overcrowding by a too-numerous, unscientific public. Nevertheless it has been sufficiently complete to show that electricity means to maintain its noble device—*Quo non ascendam.*

**C. Detaille.**

## SIMPLE EXERCISES IN TECHNICAL ANALYSIS.—VI.

By An Analytical Chemist.

### Green Paints.

Common Green (Mixed).

67. *Composition*:—

| | | | |
|---|---|---|---|
| Chromate of Lead | 2·56 | 4·6 | 24·9 |
| Prussian Blue .... | 4·73 | | |
| Oil .............. | 8·57 | 8·6 | 13·3 |
| Sulphate of Baryta | 80·02 | 72·6 | 55·5 |
| Chalk ............ | 4·12 | 14·2 | 6·3 |
| | 100 | 100 | 100 |

68. *Chromate of Lead.*—Dissolve the residue after ignition in dilute nitric acid, filter from any insoluble (sulphate of baryta, &c.), add ammonia to the filtrate till just alkaline, and hydrochloric acid till just acid, pass $SH_2$ gas to precipitate the lead as sulphide. Treat as described in Art. 11, weighing as sulphate of lead, and multiplying by 1·06766 for the equivalent of chromate of lead.

69. It is necessary that the last calculation should be verified by estimating the chromium present. The chromium, if precipitated as described in Art. 46, would be mixed with the iron from the Prussian blue, and any alumina that might be present. Alumina is not usually found in these paints, and the only substances to be separated are the chromium and the iron. This may be done in either of two ways.

70. *Separation of Iron and Chromium.*

(*a*) Add ammonic chloride and ammonia, as described in Art. 46.

This precipitates as hydrates, both the chromium and the iron. Dry, and ascertain the total weight of the two oxides. Fuse with a mixture of potassic carbonate and nitre to convert the chromic oxide into a soluble salt. Wash thoroughly with hot water, and weigh the insoluble iron as $Fe_2O_3$. Subtract this weight from the total weight found above, and the remainder gives the weight of oxide of chromium ($Cr_2O_3$) dissolved out. The latter may also be reprecipitated from the soluble portion by adding ammonia as before.

(*b*) Or instead of precipitating with ammonia, caustic potash or soda may be used. The chromic hydrate at first precipitated is readily soluble in excess of potash or soda, while the ferric hydrate remains insoluble. Add, therefore, potash or soda in excess, filter the insoluble ferric hydrate, wash thoroughly in hot water till every trace of the alkali is removed, dry and weigh, as in Art. 34. This gives the weight of oxide of iron. To the filtrate add chloride of ammonium in excess. This reprecipitates the chromium as hydrate. Dry and weigh as before.

From the weight of chromic oxide, the amount of chromate of lead in the sample can be calculated, as in Art. 46. The percentage thus found should agree very closely with that found by estimating the lead. Should the latter be in excess, salts of lead other than the chromate are present—probably the carbonate or sulphate. These may be estimated by difference in this way: The weight of chromate of lead is calculated from the chromic oxide; the amount of sulphate of lead corresponding to this chromate of lead is found by multiplying by 0·9366. Subtract the sulphate of lead from that found by estimating the lead as above (Art. 68); the difference is the amount of sulphate of lead present in the sample. If white lead, and not sulphate of lead, is found to be the salt present, multiply this difference by 0·8525 for the amount of white lead.

(71.) *Prussian Blue.*—Multiply the percentage of oxide of iron found in either of the last two processes by 2·1142 for the percentage of Prussian blue, as in Art. 59.

The other constituents are determined as already described.

### Brunswick Green Paints.

(72.) *Composition*:—

| | (1) | (2) | (3) | (4) |
|---|---|---|---|---|
| Chromate of lead and Prussian blue | 19·79 | 20·3 | 4·79 | 29·7 |
| White lead ...... | — | 79·7 | — | 62·5 |
| Sulphate of lead.. | — | — | — | |
| Oil .............. | — | — | 9·75 | — |
| Sulphate of baryta | 77·51 | — | 71·24 | — |
| Chalk .......... | 2·00 | — | 14·22 | 4·6 |
| Moisture ........ | ·70 | — | — | 3·2 |
| | 100· | 100· | 100· | 100· |

The method of analysis is similar to that for common green paints.

(73.) *Estimation of Chromate of Lead* (another method).—Boil the dry paint or the residue after ignition in caustic potash or soda to dissolve all the chromate of lead. Filter and wash; make the filtrate just acid and pass $SH_2$ gas to precipitate the lead, which is weighed as sulphate as before. The chromium is precipitated from the filtrate by ammonia, and filtered as in Art. 46; weighed, and the equivalent of chromate of lead calculated. The filtrate left after the chromium has been separated is tested qualitatively for other substances (chalk, &c.), or added to the main solution.

The insoluble in potash is boiled in acids, and anything left insoluble weighed and examined. The acid solution is freed from lead, if any is present, and any other substances in solution are precipitated and weighed as already described.

This method, when properly performed, requires less time than the other.

### Engine Green Paint.

(74.) *Composition*:—

| | | |
|---|---|---|
| Mineral matter ............ | 44 | 45·35 |
| Oil and varnish ............ | 56 | 54·65 |

(75.) This paint, as the name denotes, is used for engine painting. It differs from ordinary paints in having as a constituent varnish, which in good samples is made from copal of best quality. It is usually sold in a state ready for use. The mineral matter corresponds with that found in an ordinary green paint.

The presence of varnish is easily detected by allowing the sample to stand over night, when the varnish floats on the top. Its amount can be roughly approximated by measuring this upper layer. Its quality is ascertained by spreading the varnish with a brush on paper, and allowing it to dry. If the varnish has been prepared from best copal, it will dry very rapidly (in a few hours or less). Experience will soon enable the analyst to distinguish between good and bad varnishes.

The percentage of oil and varnish is usually estimated as for oil.

### Metallic Green Paint.

(76.) *Composition*:—

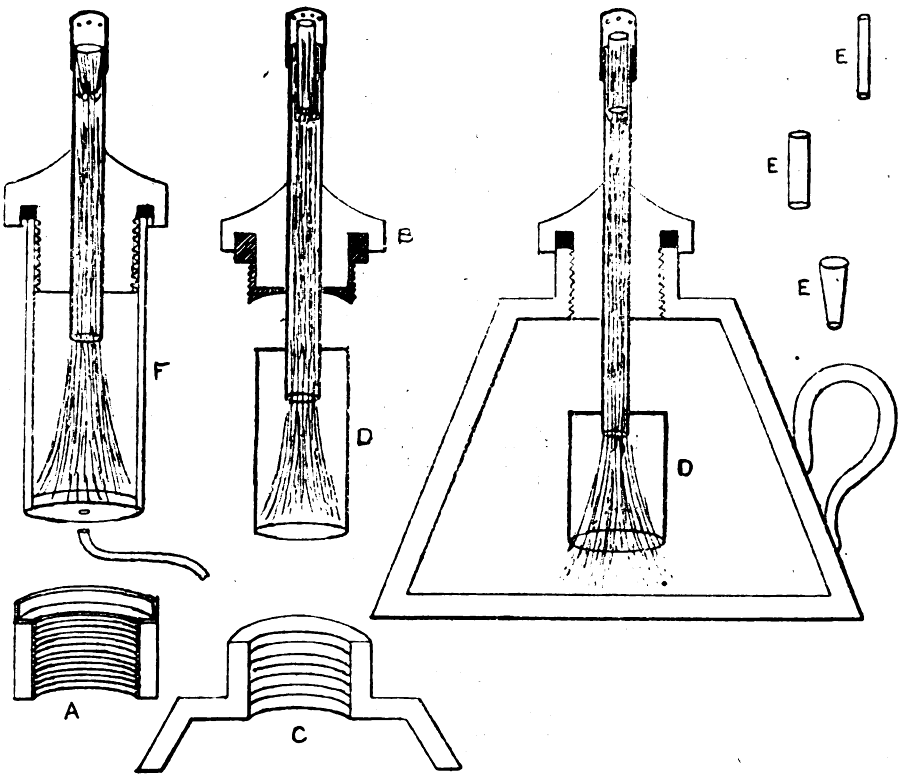
| | | | |
|---|---|---|---|
| Chromate of lead and prussian blue .... | 17·41 | 72·61 | 33·85 |
| Oil ................ | 12·06 | 24·47 | 10·35 |
| Sulphate of baryta .. | 67·35 | 2·34 | 50·92 |
| Chalk .............. | 3·18 | ·58 | 4·88 |
| | 100· | 100· | 100· |

The method of estimating is the same as before.

### Emerald Green Paint.

(77.) *Composition*:—

| | |
|---|---|
| Arsenite of copper ............... | 79·57 |
| Oil.................................... | 16·31 |
| Sulphate of baryta ............... | 4·30 |
| | 100·18 |



(78.) *Oil.*—In this case the oil must be determined by extracting with ether or other solvent, and weighing the residue when dried.

(79.) *Arsenite of Copper.*—A weighed example is ignited and the amount of residue determined. It is then treated with nitric acid and any insoluble (sulphate of baryta) weighed. The arsenite of copper is then estimated in this way: Boil off the filtrate nearly to dryness, add dilute sulphuric acid, and boil again till all the nitric acid is expelled. When cold, dilute largely and boil. When boiling add thiosulphate of soda (hyposulphite) until a black precipitate is no longer produced, and the bulk of the liquid is white from precipitated sulphur, then filter and wash, and dry at 100° C. Transfer the precipitate to a sheet of paper, and from the latter to a tared crucible; remove with sulphur the last traces of copper adhering to the paper, add the sulphur to the precipitate in the crucible, until it is nearly filled; then burn in an ignited jet of hydrogen until all the sulphur disappears. The crucible, when placed in the stream of hydrogen, is gently heated at first, afterwards strongly; and finally, it is allowed to cool, with the hydrogen gas still flowing upon it. In this operation the copper is converted into $Cu_2S$, from which the percentage of arsenite of copper is found by multiplying by 2·389.

This amount may be checked by subtracting the weight of sulphate of baryta found in the above sample from the weight left after ignition. The difference is the weight of CuO from which the arsenite is found by calculation.

### Green Bronze Paint.

(80.) *Composition*:—

| | |
|---|---|
| Insoluble silica and alumina ...... | 22·55 |
| Oxide of iron ........................ | 16·80 |
| Chalk ................................ | 37·10 |
| Chromate of lead ................. | 7·65 |
| Prussian blue ....................... | 4·54 |
| Soluble in water (sulphates and chlorides of soda and magnesia).. | 6·10 |
| Oxide of manganese and loss...... | 5·26 |
| | 100· |

### Sea-Green Paint.

(81.) *Composition*:—

| | |
|---|---|
| Prussian blue ....................... | 0·59 |
| Chromate of potash ............... | 1·83 |
| Sulphate of baryta.................. | 71·88 |
| Chalk ................................ | 12·96 |
| Oil.................................... | 12·74 |
| | 100·00 |

These paints are not of common occurrence, nor is the method of analysis difficult. We must therefore content ourselves with giving the composition, believing that they are not of sufficient importance to justify a special description.

## WOOD'S GAS-MAKER LAMP.

THE following is a description of the Gasmaker Lamp for burning benzoline and similar hydrocarbons patented by Mr. T. Wood, of Blindley Heath, Godstone, which is stated to have the following special parts and improvements forming the claims in the patent:—1st. An airtight neck at the screw of burner, in connection with compressed wick secures a safe lamp. 2nd. Economy of wick, time, and trouble, by use of small tube at burner cap. 3rd. Prevention of flooding wick by use of air chamber. 4th. Small size solid tube for supply. The lamp called the "Wood Gas-maker Lamp" may be made in metal, china, glass, or earthenware. The neck of the reservoir A must be made with a ledge or shoulder at the top of screw inside; a washer of leather, or other elastic substance must be made to fit the shoulder and to run on the screw of the burner tube. Or preferably, the B flange of the burner screw can be made with a channel, so as to allow the neck of reservoir to slide or screw within, and render the neck perfectly airtight at the screw, using the washer before mentioned. An air chamber, D, of convenient size is attached to the burner tube or flange, to prevent the flooding of the wick by the liquid. The air chamber is closed to the burner tube, or to the flange, at the top of chamber. The conducting wick is very tightly compressed in the burner tube, to just below the charring point of the cotton or wick, and from there it is met by a smaller tube and wick to supply the burner proper. E, the smaller tube, may fit the burner tube either loosely or tightly at the junction of the cap; if a loose tube is used, the wick drawn through must be returned back evenly to exclude the air. Or to attain the same end (but not so well), cotton, asbestos, or other conductive material may be used instead of the small tube. These, if used, must fit loosely. With respect to fixed lamps in which the air chamber is optional, they are supplied with liquid by solid-drawn tubing of the smallest convenient size, G, so that the bulk of the liquid may be at any safe distance from the light. The size also of the fixed lamps with supply tube can be greatly reduced. The engravings show the different parts with two kinds of lamps and three sizes of burner tube, E.

## THE REAL VALUE OF LUBRICANTS.

IF steam-users, as a body, were asked the simple question "What is the real value of a lubricant?" very few of them would be able to give a correct answer. In the majority of cases, the reply would have reference to the market prices of the different oils or lubricants, and in very few would the answer dive so far into the matter as to compare the lubricating value with the price per gallon of the oil. But the real value of any lubricant has little to do with its market price, for it depends, not only on the intrinsic qualities of the unguent itself, but also upon the economical conditions under which it is to be used. Prof. R. H. Thurston has recently presented the subject in this aspect to the notice of the American Society of Civil Engineers, and has promised to develop it more completely in the future. His note naturally takes the form of mathematical formulæ to a large extent, and will probably not attract the attention of the average steam-user so much as it might have done. According to Prof. Thurston, the correct method of comparing prices of lubricants from the user's standpoint is not one involving merely a determination of the properties of the material as a reducer of friction, and the true value of the oil is not simply proportional to its endurance and its power of reducing lost work: it includes a study of the method by which it reduces the total expenses of lessening the friction, and the extent to which the total expense for power is lessened by the reduction of work wasted in friction. The usual systems of comparison are entirely wrong, and are justifiable only by the fact that, hitherto, it has been impracticable to obtain the data required for the establishment of a correct method. Every student of the subject knows that between the power lying latent in the coals and that produced at the machine there is an enormous loss, much of which cannot be prevented so long as a steam boiler and engine intervenes. The limits of economy are tolerably well determined nowadays, and so long as they are approached the average steam-user is satisfied; but when we come to the machine itself, and look to the lubricant, we find that unless the latter is adapted to the former, and supplied in proper quantities, there is a large, and in many cases unsuspected, loss. The total cost of the lost work in machines includes, in fact, two items—the cost of lubricant, and the cost of doing the work of overcoming the friction of the lubricated surfaces. Of these items, the latter is by far the greater, and it follows that a slight saving of actual money paid for lubricants is of no practical importance in comparison with a saving of equal proportion in the cost of the power demanded to overcome friction. The cost of power includes fuel, salaries, interest on the capital invested, &c., which can be readily estimated at so much per horse-power per annum when the data are available, as they are to most steam-users. If that is known, and it can be shown that another lubricant will reduce the loss by friction to a certain amount, it then becomes a question whether the saving by the reduction of wasted power more than covers the extra cost of the superior lubricant. In the majority of cases it will be found to do so, but it may also happen in some cases that it will be more economical to use larger quantities of a lower-priced lubricant. The datum required first of all is the cost of friction, and then, when two oils are to be compared, an easily-worked formula will show the total expense per hour, the quantity of oil used being known, as well as the magnitude of the co-efficient of friction, and the cost of the lubricant. Prof. Thurston shows by examples the magnitude of the losses which are going on in consequence of the want of knowledge in purchasing lubricants and in using them. It is obvious that the value of the co-efficient of friction is the principal factor in the question, and the experiments made by Prof. Thurston show that, for instance, in light machinery, such as spinning frames, different oils will give figures varying from ·10 to ·25; under the pressures usual in heavy mill shafting the figures range from ·05 to ·10; with pressures of greater intensity, such as in the steam-engine and railroad axles, the co-efficient of friction varies with different lubricants from ·01 up to ·025, the first value being given by the best oils, the second by heavy greases. The endurance of the lubricant also varies in similar degree, and is twice as great with the best oils for the given purpose as with others of good reputation. Further, the price of the lubricant is no guide at all, for the best oils to use may be either more costly or much lower in price than others less well fitted for the work. Sperm, lard, olive, and other standard grades of oils have probably fair and well settled values, but, as a rule, the price of a lubricant is not a safe guide to selection.

---

A LARGE number of signal lamps are being fitted on the Great Western Railway with electric lamps.

---

# THE LIFE OF AN OYSTER.[*]

By Prof. Samuel Lockwood, Ph.D.

THE time was when it was enough to say of a living thing that it lived. You remember the Fool's question in "King Lear,—

> Canst tell how an oyster makes his shell?

This was simply a proverb of old. Here was a little creature, a mere clot of animate jelly, capable of building for itself a house of stone. How it did it, who could tell? No one. The Fool's question was a puzzle to the wisest. Indeed, then, and long after, it was hardly safe to seem to know too much. To-day, however, the question may be put, not only how does the oyster make its shell, but also how does the egg make the oyster? Science, now, can describe the building of the house, and can narrate the life-history of the builder and occupant. Two years ago I lectured in this place on the oyster. I desire that my address to-night shall be wholly distinct from that one. Yes, as my lecture-notes are always very brief, it is easy to forget what was said so long ago; hence I shall trust to your charity should I unwittingly at some point repeat myself. I recollect that the longest part of that lecture was devoted to the physiology of the oyster—that the three vegetal systems were discussed at length—namely, the nutritive, or food system; the circulatory, or blood system; and the respiratory, or breathing system. The nerve system was also considered in detail. Now, my desire when coming here was to make no reference to any of these four sets of functions. But I have been requested to dwell a little upon the nutritive, or digestive group of functions; and this I am glad to do, because it will enable me to speak of an organ the use of which was not known at the date of my former lecture.

You will remember that I had some large carefully-drawn diagrams. The fear of repeating myself induced me not to bring them; hence you will please follow my rude illustrations on the blackboard. I will now with the crayon outline an oyster shell. This is the right valve, the one from which the mollusc is eaten when taken on the half-shell. This large spot which I make is the adductor muscle, with which the creature pulls together its shells. It is the part which is cut through with the knife when the caterer opens the bivalve. Well to the left of this I draw four plates, or leaves, so lying on one another as to show their outer edges, which give the appearance of a frill. This series of plates constitutes the gills or breathing apparatus. Now, here we find the inner edges of these four plates to be, so to speak, soldered together, making the base of the gills; and along this base, in rows, is a series of holes. The plates are really composed of an infinite series of microscopic tubes, each tube being like a tiny flute with holes on the side. The water enters between the plates, and as the surface of the tiny tubes is covered with cilia, or fleshy hairs, these keep up a lashing by which the water is driven through the gill-tubes, and the air contained in the water is deprived of its oxygen; after which the disaërated fluid passes out at the holes in the bases of the gills. The coarse cilia, or beard, on the edges of the mantle, or thin film which enwraps the oyster, by their action make an eddy at the opened valves, into which the water rushes, bringing in the food. The outer surface of the gills is covered with the minute cilia, all helping to drive the inflowing current upward. Here at the uppermost end of the oyster, near the hinge, are four little plates, not lying upon one another, as the gill-plates do, but standing together, as it were. These are the labio, or lips of the oyster; for, in fact, the creature's mouth is simply the orifice between these two pairs of lips. When the food-laden water reaches this spot, the lips begin a sorting process, by which that which is fit for food is allowed to enter, and the unfit is rejected. The oral aperture is almost immediately over the stomach, the passage being too short to be properly called a gullet, or œsophagus. Yet the word is convenient. Thus the stomach receives the food immediately. The dark grey mass in which this organ is embedded is the liver. The oyster's stomach is literally inside of its liver. Let us now note the course of the intestinal tract. Beginning at the lower end of the stomach, or where in our own structure would be the pylorus, the intestine runs to a point considerably beyond the middle of the adductor muscle, between that and the gill bases. Here it doubles upon itself. Then, returning, it passes through the liver to a point near the oral cavity, or mouth, which it sweeps nearly over; and, winding round the liver on its other side, and then going beneath that organ, it passes beyond to the other side of the adductor muscle, in front of which the vent rests in an open space which we will call the cloaca. Here it voids its indigesta, which are immediately committed to the sea.

The liver, as you know, is bitter, a quality which the Roman epicures prized highly. But we must dwell here a minute longer, to describe the remarkable services which this large organ renders to the stomach of the oyster.

But, first, a word as to the oyster's food. A part is composed of infusoria, often called animalcules, little creatures invisible to our unaided eyes. These are easily digested. This is probably true also of the sporules of algæ, and even the unicellular algæ themselves. It is not true, however, of a large part of the oyster's food, such as the minute copepods, tiny crustaceans with limy shells; and the swarms of diatoms, very minute plants with silicious shields, which even resist the action of nitric acid. An oyster's stomach is of itself a helpless affair. It has no triturating surface, or secretors of solvent acid. But it draws all it needs from the liver. In the walls of the stomach are openings continuous into small tubes in the renal mass. Here are the bile secretions, and those of the pancreas; also the salivary glands, and the gastric follicles. We see, therefore, why the stomach is placed inside the liver—that organ is really the laboratory of the necessary dissolvents of the oyster's food.

Now it may be that one important ingredient which is contained most richly in gastric juice is supplied but feebly, if at all, from this renal source. You who like tripe hardly need be told that it is not strong food, but is of easy digestion, because of the pepsin it contains, derived from the gastric follicles of the bovine stomach. The action of pepsin is probably that of a ferment, while that of the other substances mentioned may be chemical and mechanical. Lately the microscope has given a hint in this direction, and a hint to the scientist is sometimes a God-send leading to a discovery. Here you see a little organ, like a tiny white thread of vermicilli. It lies almost parallel to the intestines, and one end of it penetrates into the stomach at its lower end. This is called the crystalline style, or rod; and a notable fact is that under the microscope it does not reveal the slightest cell structure, as a tiny morsel taken from the oyster anywhere else certainly would. What I mean is that the substance of this style is homogeneous, as if it were made of simple gelatine. Now for the hint to which I have alluded. The part, or end, which is inside the stomach, like the end of a stick of candy in the baby's mouth, is abraded, or melted away in part. The surprising fact, then, is the almost perfect certainty that this organ supplies pepsin to the oyster's stomach—a conclusion which has only been reached within a few days past, from the study of this organ in other molluscs.

But you observed the extraordinary length of the intestines—nearly three times that of the oyster's body. Now, as the food is lashed along by the numberless cilia inside the intestine through its entire length, and as the nourishing juices are taken through the walls by osmosis, you see that this arrangement subjects the entire food-supply to a thorough absorption. But the length is not all the wisdom in this digestive scheme. The intestine is not a simple cylinder. A cross section shows a convolute inner wall; it is as if a small cylinder were soldered by one side along the inside of the large cylinder along its whole length, thus increasing immensely the absorbing surface.

You may think it wonderful that the oyster should grow so fast upon such minute food. I have lately been compelled to study this matter up. Some months ago a live sea-horse was brought to me. Her scientific name is *Hippocampus heptagonus*, but we named her Hippie. It has been a joy to me to have kept her in good condition so long. But it has required some management. The fisherman who brought it was asked how it should be fed. "Oh," said he, "it isn't a fish, and so don't feed, but lives on suction." He spake wiser than he knew, as this singular fish does live entirely on microscopic life. I will tell you my secret—how I managed the matter. I gave her an aquarium to herself, and kept two large jars for breeding animalcules—that is, infusoria, &c. But these invisible things need nitrogen, and an aquarium should be absolutely clean. The problem seemed to be, how to have it clean and dirty at the same time. Now, if you drop into your aquarium a bit of fresh beef, and let it be until, like the peddler's fish, it has become a little mellow, it will generate nitrogen, and that will quicken the breeding of infusoria. When, by microscopical examination, I find that this food-supply is getting low, I transfer Hippie to one of the large jars; and, if that gives out, I place her in the other jar. By this time the larder at home is resupplied, and the little creature is restored to her proper place.

So far we have got along without much technical discourse. As I must note the leading kinds, or species, of oysters, we must resort to a few scientific names. In the extreme South there is a long narrow oyster called the strap oyster, and by the negroes, coon-heel. In southern New Jersey, in the mouth of the Delaware, on the crowded beds, the oysters, for want of room, will grow standing on their heads; hence they elongate. These are known as stick-ups. But these and some other forms are but variations of our common oyster along the entire eastern coast-line, and are all one species known as *Ostrea Virginiana*. Europe has three species. The one common to England and France, and some other places on the Continent, is *O. edulis*. On reaching Italy we find the little oyster known as *O. plicatula*. You have heard of that greediest Roman of them all, that imperial gourmand Vitellius, who ate a thousand oysters at a sitting, and who, after having the royal fauces tickled with a feather by a slave, would disburden his stomach, then fill it afresh. Perhaps the transaction was possible with the little *Plicatula*. But what about such specimens as the *Virginiana*, which Mr. Thackeray was invited to grapple with in Fulton Market? Three individuals filled his plate. Said an English lady to whom he was relating his experience: "Why, Mr. Thackeray, what were your feelings?" "Well, I felt, in attacking but one of them, that it was like trying to swallow a baby." A thousand "Virginias" would have been trying to the vitals of Vitellius. The fourth oyster to be mentioned is the one whose original home seems to be the Tagus in Portugal. This species is *Ostrea angulata*. It is said to be the one whose shells were used in the ostracism, or vote of banishment, in ancient Greece.

---

[*] A lecture delivered before the New York Microscopical Society.

The four species mentioned are all that have any place in commerce. The oyster native to France, Northern Europe, and England, is the *O. edulis*. This species, and the Italian, *O. plicatula*, are hermaphrodite, or bisexual, while the Portuguese, *O. angulata*, and the American, *O. Virginiana*, are unisexual. In these species, as among the fishes, there is a true spawning of eggs by the female, and a fecundating of them in the water which has been fertilised by the presence of the male. But with *O. edulis* and *O. plicatula* there is no spawning of eggs at all. The eggs are retained between the lobes of the animal, and there hatched, and when emitted into the water, are already well advanced, each having a pair of perfectly formed shells.

The English oyster, *O. edulis*, is capable of producing a million and a half of spawn in a season. But it is shown to a demonstration that our American bivalve, *O. Virginiana*, can produce in one season—that is, in the r-less months—from twenty to twenty and a half millions of spawn. But these are simply eggs, and do not get the start of the spawn which is emitted already hatched. However, I do think that there is some relation between our American push and our physical environment. It is a characteristic of the country. An insect ordinarily well-behaved on the other side of the ocean, so multiplies, if it but immigrate here, as to become a pest and a defiance.

How does the oyster make his shell? At a recent meeting of the American Association for the Advancement of Science a paper was read asserting that the extreme age of an oyster is twenty years. Now I had previously, in an article in the *Popular Science Monthly*, demonstrated that an oyster might be in fair edible condition at the age of thirty years. Here are the shells of one of the oysters on the characters of which the statement was based. This double shell is thirty years old, and the inclosed mollusc was large and in fair condition. But of this specimen more anon. In building its shell the oyster starts with the hinge ends, at the spot known to conchologists as the *umbo*. A small plate, or single scale, now represents each valve, and that is the first season's growth. The next season a new growth, or plate, shoots out from underneath the first one, just as shingles do. The oystermen call these laps, or plates, "shoots," and they claim that the number of shoots indicates the years of the oyster. They certainly do contain a record of the seasons, showing the slow-growing and the fast-growing seasons. But there is often great difficulty in clearly differentiating these shoots. The record is often obliterated in places by the growth of parasites, which build their shells or tubes upon the oyster. I have likened these shoots to shingles. Now, at the gable of a house these shingles may be seen edgewise. So on the side of an oyster-shell is a series of lines. This is the edgewise view of the shoots, or season-growths. Another factor is this purple spot, or scar, in the interior of the shell. It is the place of attachment of the adductor muscle. Its first place of attachment was close up to the hinge. Had it stayed there until the shell had become adult, how difficult would be the task of pulling the valves together; the leverage to be overcome would be so great; for we must bear in mind the fact that at the hinge end the valves are held by this black ligament, which is, in life, elastic, swelling when the shell opens, and being compressed when the animal draws the values together. So, with every year's growth, or elongation of the shell, the mollusc moves the place of attachment of the muscle onward, that is, an advance further from the hinge. As it does so, it covers up with white nacre all the scars that are back of the one in actual use as the point of attachment of the muscle. This you can prove by eating off with nitric acid this covering, and thus exposing the whole life-series of scars, or attachments.

I have likened the oyster's shoots, or season-growths, to the shingles on a roof. To make the similitude complete, it would be necessary for the bottom shingle on the roof to underlie the whole series, and reach even to the roof-tree, or ridge-pole. Then the second shingle from the gutter must in like manner underlie all the rest of the series; so of the third; and so on with the rest. In this way lie the shoots, or laps, of the oyster's shell. The last one deposited underlies them all, and every one terminates at the channel in the bill—so that this groove in the bill contains a series of transverse lines, each one marking a season, or year. Thus we get really four factors for the solution of the question, "How old is the oyster?" all of which are the outcome of the method or way of making the shell.

Now for the story of the shell in my hand. This, with another, was given me by an intelligent oyster-raiser at Keyport, N.J., with the question, "How old are they?" My answer was: "About thirty years." Said he: "You have hit it. In 1855 I planted a bed of oysters on a clean sandy bottom. But they did not do well. Oysters want, at least, a little mud. The next year we took them up for the market; but they were poor. So we dredged the bed, and did not plant there again. This year I thought we would examine that bottom, and, to my surprise, we took up these two oysters, which evidently were left of that planting thirty years ago. I opened them, and they proved to be of fair quality." Does not this agreement between the naturalist and the oysterman deserve to be called a demonstration?

How does the oyster begin life? I shall now speak only of the American oyster, whose earliest babyhood is so different from that of the English mollusc—since theirs is emitted in an advanced stage of development, while ours is emitted simply as an egg. In the r-less months our oyster-beds are, many of them, marked by the appearance of little clouds of a milky hue. These proceed from the female oyster, which snaps its shell, and thus emits its spawn into the water. The male, in like way, emits the fecundating milt; but, to the eye, this is invisible. The eggs, sinking to the bottom. fall in with some of the milt in the water, and the spermatoza at once attach themselves to them. As seen under the microscope, the tiny egg becomes like a bur—that is, as if it were beset on the surface with cilia. In a word, it is fecundated, and with this addition of life it mounts up from its bed and floats away. In two or three hours the egg is hatched, and the development of the little creature begins. At first, it is a little triangular thing. It now begins to swim actively. But how does it do it? From what we might call the base of the angle which outlines the little thing, you see a pad projecting. Really it is a brush of cilia, every individual of which is lashing its way with the force of a projectile. In a very few hours a spot appears on each side of the apex of the triangle. Each spot is the beginning of a shell, or valve; and the fact of its beginning where it does, at what we have already called the umbo, has caused Dr. John Ryder to name this the umbo stage of the oyster's life. Nature in her work with an egg seems to delight in developing toward a side. In this way she starts a fish, a reptile, a bird, and a mammal. But our "midget" oyster is perfectly symmetrical—each valve, or side, is the exact counterpart of the other.

This roving life of the embryo oyster exposes it to infinite perils. It is certain that of the twenty or thirty millions of eggs emitted, not more than an average of two or three individuals will attain a size fit for the market. If all were to survive, such would be the growth of oyster-beds that coastwise navigation must cease. But the waste is simply enormous—so many are the enemies and so various the perils of the infant mollusc. To devise wise methods of artificial culture is now the great problem on which the scientific men of the U. S. Fish Commission are at work. That done, we may hope for some arrest of this stupendous waste.

I suppose our young oyster to have stopped his roving life. He has made an attachment, wise or unwise. And strange attachments he does sometimes form. I have in my collection quite a display of eccentric, if not discreditable, ostrean alliances. I have one oyster which is hugging desperately a ring-bolt, another devotedly attached to a decanter, and, again, no less than half a dozen ardently attached to a whisky bottle. Whatever may be the object chosen—and anything will do that serves as an anchorage—the mollusc, if not disturbed, stays there for the rest of its natural life.

Let us suppose our little oyster now attached to its object. It is yet the merest atomy of life—a microscopic object—and, it is likely, not much over a day old. But in that atom, and during that time, how rapidly the life forces have worked! The little thing now puts all its powers at house building. First, it lays the foundation by placing itself on its left side, in order that the hollow, or dish-shaped valve, may be cemented to its anchorage. There is now a secreting and exuding of a horny substance, of a mucilaginous consistency, which is called concholine. This is laid down on the rock, or other support, in a meshy form, just like a tiny wad of the finest conceivable lace. Into these meshes percolates the carbonate of lime held in solution by the sea water. In this way is the foundation laid. Next, there is a spreading out of the shells on asymmetrical lines—for the valves are becoming inequal and dissimilar. But during this foundation work, what about food-getting? Perhaps we shall see.

One of the first serious studies of my young days, in zoology, was the question, What becomes of the tadpole's tail? I carried a tadpole into froghood. He had ceased to be a gill-breather, and, having lungs, must emerge from the water, and come to the air. Nor could he any longer live on carrion and putrid plants. He must now hunt the living insects. Such a change is hardly less than a shock. I observed that my frog kept still, but bearing his tail behind him, which, of course, was the proper place, if he must carry it at all. Now it was just this "at all" which perplexed me. The books said that the tadpole's tail is lost by atrophy—that is, that it dries off. Nonsense! Nature does not entail such a waste of the raw material. I watched the frog day by day, and discovered that the caudal annex was being absorbed. It was getting shorter, but the shortening was going on at the thick, or proximal, end. Now, so it was—every particle of that appendage was taken in. This done, the animal had to forage for subsistence. And similarly is it with our baby oyster while laying the foundation, and shaping its house. That prominent organ, the swimming pad, is getting absorbed—for it is now its food-supply. It is now developing internally, for as yet there is but little more than the beginning of things. The intestine is simply a short, straight organ, and is not yet convolute. But the liver is very large: in fact, it quite preponderates.

And what of Ostrea's life? Who are her friends? There is a pretty red branching sponge, which often grows upon the oyster, *Microciona prolifera*. Formerly it was very common. It is less so now. This sponge often serves the oyster well, in buoying the bivalve up when sinking in the mud. It is also, in its way, a grove in which the infusoria breed, and so supply food to the mollusc. The oyster, too, has a gay "commensal." I like this pretty old word of Chaucer, meaning one who dines at our table, and is welcome there. Of course, all this precludes the idea of a parasite. This gay little commensal is a red and white crab hardly larger than a pea. It lives literally in the oyster ensconced between the folds of the mantle, but it does not live upon its host. Between them both there seems to be a good understanding. It is the female *Pinnotheres ostreum*. Experienced oystermen have told me that it is rarely found except with oysters in good condition. The curious fact is that it is only the female *Pinnotheres* that live in the oyster. The male is often seen floating on the surface of the water, with a pretty white anchor on his jacket, the gay little sailor that he is. His general hue is brown. He has a harder shell than the female, whose shell is thin and transparent. The truth is that, though twice as large as the male, she is very tender, and her coddling life as a commensal is a necessity. The red sponge I have mentioned is called by the oystermen "red-beard." There is another object that delights to grow upon the oyster, which they call "grey-beard," and sometimes "grey-moss." It is one of the Bryozoa. The one that I have often found is *Sertularia argentea*, an exquisite creature; for, though looking like a delicate silvery alga, it is not a plant at all, but a finely branching zoophyte, or community of exquisite living animal florets. This serves the oyster well in much the same way as does the red sponge.

But our oyster has many enemies. The boring yellow sponge, *Cliona sulphurea*, eats very minute holes into the shell, so numerous, and so winding, as in some instances to cause the shell to fall in pieces. These minute holes, under the microscope, show gouges at their edges, as if they had been cut with chisels, like post holes. But the process is as yet a mystery. The great winkles, *Sycotypus canaliculatus* and *Fulgur carica*, with their file-tongues, will rasp off the nib end of the oyster shell, then introduce the sucking siphon, and so consume the mollusc at their leisure. The little drill, *Urosalpinx cinerea*, is a severe pest. This shell and the two just mentioned are spiral univalves. The drill is a small shell rarely measuring ¾in. in length, and its lingual ribbon or file-tongue with its armature of several rows of sharp teeth, is microscopic. I have watched it at work, and I think that the little burglar bores a hole through the oyster's house by crooking its tongue, as I do my finger, letting the knuckle represent the bend, or crook of the file tongue, in which case the teeth would stand out like a brush; which brush twisted around and back again, in a three-quarter or perhaps entire circle, would represent the action of a drill. The hole is always perfectly symmetrical, and generally is countersunk at the place of starting. The hole completed, the tiny siphon tube of the mollusc is introduced, and the soft parts of the oyster are taken up. Sometimes the drum, *Pogonias chromis*, inflicts severe damage on an oyster bed. This singular fish has in the upper part of its throat very large, and solid, pharyngeal bones, which are covered with closely-set, hard, round, pavement teeth, not unlike the cobble stones of old. With its front teeth it picks up an oyster, and it crushes it with the pharyngeal teeth, and then swallows it. This fearful creature gets its name from a booming noise which it is able to make. One year a school of drums entered Raritan Bay, and destroyed many thousands of dollars' worth of oysters in a single night. Excepting man himself, the worst enemy of the oyster is the five-finger, or sea-star, *Asterias arenicola*. A sea-star is an object with five rays, and is of the consistence of soft leather. If we turn it over, we observe a canal along each ray, or finger, through its entire length. On each side of this canal is a row of ambulacra, or little feet, each with a sucking disc at its extremity. At the centre, or base, of the rays is the oral cavity, in which is the stomach sack, which is capable of being everted and protruded. It is a blind sack, but its walls will, by osmosis, take up food. With these five rays, and their thousands of little suckers, it will grasp an oyster, and, waiting until the mollusc opens, be it never so little, it will thrust in its everted stomach, and suck out the oyster's life. I have not demonstrated the point, but my belief is that the sea-star has some urticating power, and even paralyses its victim. To the oyster raiser, the star is often a calamity. Many thousands of bushels are sometimes taken by it in a season from the beds. Other enemies there are, but time is wanted to speak of them.

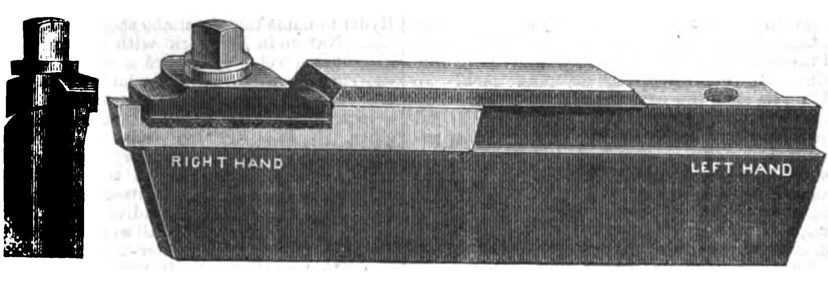
I must say a word on the pearl. Though not the pearl oyster, our mollusc is a pearl maker. Nacre, or mother of pearl, constitutes, to a greater or less extent, the shells of all oysters. But the isolated individual pearl, that which is accounted a gem, and the worthy decoration of a bride, is always an enforced product. It is made upon occasion of inconvenience, suffering, or disease. It was a pretty coincidence this morning, that, having just finished thinking out the brief for this address, I looked into Shakespeare, and alighted on that expression of Touchstone: "Rich honesty dwells like a miser in a poor house, as your pearl in your foul oyster." It is surely interesting that this wisdom of the poet, drawn from the proverbial lore of the people, finds its verification in science. The pearl is the outcome of suffering. It is elaborated in distress. So delicate, so mild, so exquisite. It is already perfect—the one only gem that does not ask the lapidary's skill. And how many a precious thought, having passed through the alembic of suffering, has crystallised into a living form, a thought-pearl of purity, ethereal and immaculate! And now, my friends, if our discourse has enabled us to know better one of God's lowly little creatures, we have done well, since it will help us to love the Creator more.

## THE RETRIEVING HARPOON.

THERE was found in universal use at Point Barrow, Arctic Alaska, a peculiar form of harpoon, exclusively used, as the name I have suggested for it implies, for retrieving seals that have been shot in open holes or "leads" of water, within darting distance from the edge of the ice. The Eskimos call call it "*naú-li-gû*." It consists of a long light shaft (*i-pù-ä*) of wood, about one inch in diameter, and generally about five feet long, though the length varies with the height of the man who uses it. The butt of this is armed with a slender bayonet-shaped ice-pick (*tú-u*) of walrus ivory, about fourteen inches long, and to the other end is securely fastened a heavy pear-shaped foreshaft (*u-ku-mai-lu-ta*, "weight") of walrus ivory or compact bone, which serves to give weight to the head of the harpoon and make it fly straight. It is about five inches long and an inch and a half in diameter at the forward end. In the centre of the end of the foreshaft is a deep round socket, into which fits the butt of a slender rod of ivory about two inches long, the "loose-shaft" (*i-gi-mû*). This is secured to the foreshaft by a thong passing through a hole drilled in it, so that it can be easily removed from the socket, while the thong prevents it from being dropped and lost. On the tip of the loose-shaft fits a detachable toggle-head (*naú-lû*) of the ordinary type common to the whole Eskimo race, provided with a long line of seal thong upwards of ninety feet in length. When ready for use the line is drawn taut from the head to about the middle of the shaft, made fast by a couple of half-hitches, and kept from slipping by a little ivory peg (*ki-ler-bwin*) inserted into the shaft. Just back of this there is also a little curved ivory knob (*ti-ka*) secured to the shaft as a rest for the forefinger in aiming the weapon. The hunter on starting out carries his rifle slung in a sort of holster across his back, and secured to this the *naú-lû* and line folded in long hanks. The rest of the harpoon is carried in the hand and serves as a staff in walking and climbing among the ice-hummocks, where the sharp pick is useful to prevent slipping and to try doubtful ice, and also enables the hunter to break away thin ice at the edge of a hole so as to draw his game to the solid floe. It can also serve as a bayonet for defence in case of necessity. When a seal has been shot and floats, the *naú-lû* and lines are fitted on and the weapon darted with the right hand, while the left holds the end of the line. The *naú-lû* enters the animal entirely, and a pull on the line causes it to slip off the top of the loose-shaft (which is facilitated by the play of the latter) and to toggle securely under the skin. The whole is then drawn in by the line. The use of this weapon appears to be confined to Northwestern Alaska, and it is very rarely found south of Behring's strait. In the large collection made by Mr. E. W. Nelson, in the neighbourhood of Norton sound, there is only one rather clumsily-made *naú-li-gû*, with a fragment of the line, which is labelled a "beluga spear." It is manifestly unfitted for such use, but this statement goes to show that it was an unfamiliar weapon among the people by whom he was surrounded. The natives of that region, as well as the Greenlanders and Eastern Eskimos, retrieve seals with the kaiak, accasionally using the stabbing harpoon, common to the whole Eskimo race, to secure a seal, but they are unprovided with any special weapon for retrieving. We were unable, during our stay at Point Barrow, to ascertain whether this weapon was in use before the introduction of firearms, which were now universally employed, but I am strongly led to conjecture that it is a modern invention. I am of the opinion that the people of this limited area, enabled by the introduction of firearms to kill seals in the open holes of water, where they had previously been safe from the ordinary spear, and prevented from using the kaiak from the extreme roughness of the ice, invented this weapon by reducing the great walrus-harpoon to a convenient size for carrying on the ice. It is a perfect miniature of the walrus-harpoon, with the addition of the ice-pick, an essential part of the ordinary stabbing harpoon. I am strengthened in this opinion by the fact that Dr. Simpson, who spent the winters of 1852-3 and 1853-4 at Point Barrow, before the general introduction of firearms, makes no mention of the use of this weapon in his excellent paper on the Western Eskimos. He would undoubtedly have done so had he seen it, so different is it from the ordinary Eskimo methods of seal hunting.—John Murdoch, in the *American Naturalist*.

## THREADING TOOL FOR SQUARE THREADS.

THE Hartford Tool Company, Hartford, Conn., have recently brought out a tool-holder and tools for cutting square threads, which must, says the *American Machinist*, prove a convenience to those having much of this kind of work to do, as well as much cheaper than the ordinary practice in this respect. Square threads would undoubtedly be used more than they are but for the trouble and expense of cutting them. The engraving needs but little in the way of explanation. Right-hand threads are cut with one end of holder forward, and by simply reversing holder and cutter left-hand threads may be cut. The strap which clamps the cutter has an elongated hole, and adjusts itself to different widths of cutter, pressing the cutter against straight side of holder, and holding it rigidly in place. The cutters are concaved on the sides requiring clearance. When nice work is required, a cutter one size smaller than that required for finishing can be used for roughing out. Should a cutter require sharpening before the thread is finished, it can be taken out and ground without disturbing the holder; then, when replaced, it will be exactly right to resume its cut. The holder is of a size to fit the ordinary tool-post.



## THE DURABILITY OF LEATHER BINDINGS AND GELATINE NEGATIVES.

IN a note on this subject contributed to the *British Journal of Photography*, Mr. W. H. Harrison says:—Recently I drew attention to the circumstance that gelatine negatives not treated with alum, or other strong hardening or tanning matters, probably have not within them the elements of permanency in as strong a degree as those which have been so soaked, and the authority of the late Dr. Van Monckhoven was quoted to the effect that alum-treated plates are more imperishable than others. The fact was also mentioned that Hungarian, or other leathers, tanned or hardened with alum, are more harsh and less waterproof than leathers tanned in the ordinary way, which now raises the additional question, whether it is possible to well tan negatives in a proper way, without imparting to them an injurious stain. For the benefit of those who may wish to work out this problem practically, it may be well to state that vegetable astringents differ in the hardness and durability of the leathers they produce. Oak-bark infusion is slow in action, but produces a first-class leather. Infusion of valonia, prepared from the acorn-cups of an oak of the south of Europe, gives a hard and heavy leather. Red catechu, or cutch, is very cheap, and tans quickly; so also does the pale catechu, known as gambier, but the leathers produced by the catechus are soft and spongy, unless some other tanning materials be added to the infusion. Good leather is scarce in the shops nowadays, and high in price, because of the great length of time it takes to tan. It has a strong "leathery" smell, the well-known smell being due to the oak-bark, and not to the original hides. When this particular smell is present in the leather in strength, it is a good sign, though not all that is requisite to afford materials for sound judgment whether the leather was entirely tanned by oak-bark infusion, and for a long time. As to the durability of leather, I recently published some information obtained from the Egyptian department of the British Museum, and since then, to glean facts of use for the purposes of this article, have seen Mr. W. Y. Fletcher, who has extensive experience as to the durability of various leathers used in the printed-book department of the national library. In that department the dates of the bindings of books go back to about the year 1450 or 1455, and some of them are in very good condition. There has been a falling off in the quality of English leather during the last hundred years, probably in consequence of the demand for cheapness, therefore for rapid tanning. The chief point of interest he gave me having a bearing upon photography, is that morocco leather is decidedly the most durable leather for the bindings of books. This is made from different skins—namely, those of the goat, seal, and sheep, but the tanning material is one—namely, sumach. It takes but twenty-four hours to tan a sheepskin with this substance, so probably twelve hours or less in it would be sufficient for a gelatine plate. Another point which may be in favour of sumach is, that the Sicilian variety, which is the best, is used to tan leather white. Whether it would gelatine an opaque whiteness, or leave the film transparent, is a matter for experiment. The material is cheap enough, the prices in the London market varying from about 15s. to 16s. 6d. a cwt., and it may be obtained in the pulverised form. Sumach is a small plant which grows wild in southern Europe and southern America, but is also extensively cultivated for commercial purposes; this cultivation is carried on to a considerable extent in Italy. The leaves are the portion of the plant used in tanning. Next in durability to morocco leather, says Mr. Fletcher, comes roan, which is prepared from sheepskin; calf is worse, and Russian leather worse still. Among the curiosities of binding we examined, was that of a book bound in deerskin and wooden boards, published in 1485, and still in good condition. There are, of course, many books bound in vellum; modern vellum cracks very much with time. Plenty of morocco-bound books of about the end of the 15th century are still in excellent condition. There is an ugly rumour afloat, that the best "Turkey" morocco comes from Switzerland, and the best "Levant" morocco from Austria. Some of the books in the Museum, bound in tanned pigskin, have lasted well. One book there is bound in the skin of the kangaroo; this is in the King's Library, and was presented, at Botany Bay, to Sir Joseph Banks, in 1789. The artificial colouring matters of leather do not seem to injure their durability. This general information is penned in the hope that those who wish to develop a process for rendering particular negatives exceptionally durable, will try the effect of tanning the films with suitable vegetable astringents. Most of these astringents are absorbents of oxygen, consequently likely to be developing agents. In solution with an alkali, if any such mixture should bring out a picture well, there would be the satisfaction of knowing at the time that the negative was rendered more durable; the slower such development, the greater would be the permanency of the result. Gallic acid, so often used in the past for paper and other negatives, is not a tanning agent; pyrogallol probably has a feeble influence, however, in that direction.

# SCIENTIFIC SOCIETIES.

◆

## ROYAL ASTRONOMICAL SOCIETY.

THE April meeting of this society was held on the 10th inst. at Burlington House, Mr. Ed. Dunkin, F.R.S., President, in the chair.

Lieut. S. G. Burrard, R.E., Dehra Dun, India; Mr. J. H. Honeyburne, M.A., 97, Mulgrave-street, Liverpool; Mr. Jas. McKerrow, Surveyor-General of New Zealand, Wellington, N.Z.; Mr. John A. Westwood Oliver, 13, Bruton-street, Berkeley-square, W.; and Major Harry T. Watson, Langley House, Slough, Bucks, were balloted for, and duly elected Fellows of the Society.

Captain Noble asked whether the *Monthly Notices* could not be issued earlier, so as to give Fellows an opportunity of examining them before the meeting.

Mr. Knobel said that he was glad the subject had been mentioned, as he should like to take the opinion of the society as to whether it was desirable to hurry the printing of the numbers when they contained, as in the present instance, diagrams and woodcuts, which took a long time to prepare.

Mr. Chambers said that the explanation of the delay which had been given was the periodical explanation, which at tolerably regular intervals had been given for the last 20 years. Great care should of course be exercised in correcting for the press; but he thought that it would be more satisfactory to the Fellows if the longer and illustrated papers were kept back for another month rather than that the issue of the number should be delayed for them.

Captain Noble said that when Mr. Proctor edited the *Notices* they were always published about a week before the meeting.

Colonel Tupman said that he should like to hear from Captain Noble what difference it would make to Fellows if they did not receive the *Monthly Notices* before the next meeting.

Captain Noble said that subjects were often discussed having reference to papers read at the preceding meeting, and unless Fellows had had an opportunity of reading the papers they could not follow the discussions.

Professor Adams hoped that the editors would never hurry the publication of the *Notices* for the purpose of getting them out before the next meeting; accuracy should never be sacrificed for the sake of expedition.

Mr. Green exhibited a drawing of Saturn, which showed the belt upon the body of the planet, to which attention was drawn at the last opposition by Mr. Ranyard. Mr. Green had not been able to observe Encke's division in the outer ring, although he had had several very favourable opportunities for observation during the recent, as well as during the preceding, opposition. He was disposed to think that the appearance which had been described was due to inequalities of tint in different parts of the outer ring, which when seen with a smaller aperture might give the appearance of a division. Many drawings also showed a sharp line of demarcation between the inner ring and the crape ring; but to him it had always appeared that the crape ring merged gradually into the brighter ring outside it. In former years he had considered that Saturn was a more favourable object for definition than Jupiter; but during the past opposition the general sharpness of the details seen upon the body of the planet seemed to be decidedly inferior to those upon Jupiter. He had at no time seen a bright spot near to the southern pole of the planet, such as was shown in some drawings; but there was a great deal of detail visible in the polar cap, which extended down to within a short distance of the dark belt before referred to.

Mr. Ranyard said he concurred with Mr. Green as to the gradual merging of the crape ring into the brighter ring outside it. The dark belt shown in Mr. Green's drawing was somewhat broader and lower down towards the equatorial regions than it appeared to him, and he thought that the polar cloud cap was more uniform in tint than it appeared in Mr. Green's drawing.

Mr. Knobel said that there had evidently been a great change in the appearance of the markings on the planet during the last two oppositions.

Captain Noble said it might be interesting to possessors of moderate optical means to know that he had seen the dark belt on the body of the planet quite distinctly with an aperture of $4\frac{2}{10}$in.

The President, after returning thanks to Mr. Green for his drawing and explanations, said that the meeting would be pleased to hear that Prof. Langley, the Director of the Allegheny Observatory, was present, and they would be glad to hear some account of the work upon which he was engaged.

Prof. Langley said that he was quite unprepared to make any formal report to the meeting, as he was not aware that he would have been called upon. For the last four or five years he had been engaged in a study of the energy which comes to us from the sun, regarded not merely as light, but also as heat. He had also been studying the obstacle which our atmosphere offers to the transmission of radiations in different parts of the spectrum. For this purpose he had made use of an instrument more delicate than the thermopile, to which he had given the name of "Bolometer." It consists of an extremely fine wire, through which an electric current passes, and on which heat falling causes change in conductivity, which is indicated by a deflection of the needle of a delicate galvanometer. By means of this instrument he had mapped the spectrum at the infra-red end, and had traced lines in a region far beyond that which had been photographed by Captain Abney. The wire of the bolometer was placed at right angles to the length of the spectrum, and as it was passed up and down the spectrum it indicated the presence of dark lines as cold regions. The instrument was so sensitive that although the grating spectrum has only in certain parts of the spectrum about $\frac{1}{400}$th of the intensity of the prismatic spectrum, yet he had been able to explore the infra red region to a distance three or four times further below the lowest visible portion than it had been explored by means of photography. In the case of the lunar spectrum, this infra-red region had been explored with a train of rock-salt prisms, and his experiments showed that the infra-red region was relatively much richer in the lunar than in the solar spectrum, indicating that there was dark heat emitted by the moon. In the course of these experiments he had made an expedition to Mount Whitney, and had encamped at a height of 15,000ft. in the Sierra Nevada. He was greatly struck with the immense advantages afforded by great altitudes for observers in physical astronomy, and especially with the good definition as well as the admirable transparency of the atmosphere, which afforded opportunities of photographing nebulæ and observing double stars and faint objects which could not be obtained at lower altitudes.

Mr. Stone said that some years ago he had attempted to make observations with a thermopile, which was probably not nearly so delicate an instrument as that used by Prof. Langley, and had found very serious difficulties arising from constant changes in the absorption of the atmosphere. As long as he made use of only one thermopile, he found that he was simply registering variations in the absorption of the atmosphere; but he succeeded in getting over this difficulty, and obtaining quantitative results more or less satisfactory by using two thermopiles, one of which registered the heat from the star or other object of which observations were being made, and the other the heat derived from an adjacent portion of the atmosphere.

Mr. Common inquired how the wire of the bolometer was made?

Prof. Langley said that he had, in the first instance, made use of a thin strip of iron 1-15,000th of an inch in thickness; but the iron was liable to rust and change, and he had more recently used a platinum strip 1-25,000th of an inch in thickness, and with a breadth of 1-120th to 1-250th of an inch, like an extremely minute piece of tape, which was mounted in a frame like the frame of a micrometer, and could be pushed on to different parts of the spectrum by a micrometer screw. He had experienced the differences of absorption referred to by Mr. Stone, but he had not found that they caused an insuperable difficulty in making measurements, as in a clear sky they only corresponded to differences of about 8 or 10 per cent., which could be eliminated by a series of measurements. These variations were reduced to a minimum by inclosing the bolometer in a long tube with diaphragms, which excluded lateral radiations.

The thanks of the Society were returned to Prof. Langley for his very interesting address.

Mr. Common exhibited a series of enlargements of photographs of the nebula of Orion taken with different exposures, varying from a few minutes up to sixty minutes. With the longer exposures the outer and fainter portions of the nebula were shown; but the inner and brighter portions were obscured by over-exposure. It was only by a combination of such pictures that the whole of the details visible in the nebula could be studied. With the longer exposures regions of the nebula invisible to the eye with the telescope registered themselves on the photographic plate. With sixty minutes he had obtained traces of many stars invisible to the eye. He had not at present tested what could be obtained by still longer exposures.

The following papers were presented or taken as read:—"Occultations of Stars by the Moon in the Years 1876-80, and Resulting Final Equations between the Errors of the Tables and the Errors of Observation," by Lieut.-Col. G. L. Tupman; "Occultations Observed at Forest Lodge, Maresfield," by Captain W. Noble; "Occultations of Aldebaran, 1885, Feb. 22, Observed at Dun Echt, Aberdeen, and Observation of Jupiter, 1885, Feb. 18, made at Dun Echt, Aberdeen," by Dr. R. Copeland.

## ROYAL MICROSCOPICAL SOCIETY.

THE seventh meeting of the session was held on the 8th inst., at King's College, Strand, W.C., the president, the Rev. Dr. Dallinger, F.R.S., in the chair.

Mr. Crisp, remarking that it had been said "there was nothing new under the sun," referred to Schieck's Revolver Microscope exhibited in December, 1883, in which a drum revolved beneath the objective with the objects arranged on the periphery, so that by turning the drum they were brought successively into view. The novelty of the microscope was challenged, and one on a similar principle was produced, made nearly 60 years earlier by T. Winter, which was considered to be the earliest of all such forms. It now appeared, however, that Winter had been anticipated by one made two centuries ago. This was proved by a description and illustration of such an instrument which appeared in an old Italian book, without title page, which, together with a model of the instrument, was handed round for inspection. The first page commenced: "Nuove Inventioni di tubi ottici dimostrate nell' Accademia Fisico-matematica Romana, l'Anno 1686."

Mr. Beck said that the interesting portion of the instrument was the spring which was used for adjusting the focus of the lens, because that was the subject of a patent which had been taken out about 15 years ago.

Mr. H. G. Madan said the form of polarising prism recently suggested by M. Bertrand in the Comptes Rendus,* and also described in the Society's *Journal*,† he thought would interest the Fellows, as it was almost the only one which had yet been seen in this country, added to which it was always more interesting to see a thing in the flesh than merely to read a description of it. By the aid of diagrams on the board he explained that the prism consisted of a four-sided parallelopiped of dense glass about three times as long as broad, and having a refractive index of 1·658, the same as that of calc-spar. This was cut through obliquely in the same way as in an ordinary Nicol prism, making an angle of 76° 43′ with the terminal end. A thin cleavage plate of calc-spar, not more than 1mm. in thickness, was placed between the two pieces of glass, and the whole were cemented together with a cement having a refractive index not less than that of the glass. It worked in the same way as the Nicol prism, except that it was the ordinary ray which emerged instead of the extraordinary ray, the index of the former being 1·658, and that of the latter 1·48. It would be seen that when a ray of light entered the prism and passed through the glass and the cement, it would meet the calc-spar, and be thereby separated into two rays, and then, passing on, the ordinary ray would meet a medium having the same refractive index and would pass straight on, whilst the extraordinary ray meeting with a substance of different refractive index from its own became totally reflected. In this way the extraordinary ray was got rid of, but the ordinary ray passed through as if the prism had been solid. The principle of the construction of this prism was known to Jamin in 1869, and it had been more lately (1884) described by Feussner; but the credit to which Bertrand was entitled was in the use of a cement which had the high refractive index of 1·66. The great advantage which this prism possessed over the Nicol prism, apart from its cost, was in the larger field which it was possible to obtain. One defect in the prism arose from the great density of the glass, which, being due to the large percentage of lead which it contained, made it very apt to get tarnished. He suggested, as an effectual preventive of this evil, that a piece of thin microscopic glass should be cemented upon each end, which, by keeping off the air, would entirely preserve the surface without impairing the efficiency of the prism in any way. Mr. Madan also exhibited another form of polarising prism, which was a modification of Ahrens's double-image prism, in which a very great divergence of the beams was obtained by the combination of three prisms of calc-spar and one of dense flint glass, the glass merely being used as a correcting prism. This form was very effective as a double-image prism; but he found it was possible to get rid of the other ray entirely instead of merely turning it aside. This was done by including a thin film of air, and by means of this, if the surface did not exceed 14°, the ordinary ray was totally reflected and passed off. There was, however, in this arrangement a great over-correction for colour, so that the blue rays were much more deviated than the red, in the proportions of 12° 20′ and 12° 35′; this had to be corrected first by putting on a crown glass prism beyond the film of air, and then the colour correction was effected by the addition of another prism of dense flint glass, after passing which the extraordinary ray left the arrangement corrected for deviation and almost corrected for colour. The incident light must be limited to 28°, and they then obtained on one side a field of 30°, and on the other of 14°. He did not think it was much better than Ahrens's prism, from a practical point of view.

---

* Comptes Rendus 99 (1884), pp. 538-40.

† Vol. IV. pp. 965.

The President said the society was much indebted to Mr. Madan for these details, which showed a great amount of ingenuity.

Mr. Cheshire said it was of course of great value to be able to get such a large field; but it occurred to him that in Mr. Madan's modification of Ahrens's prism there must be a considerable loss of light in the case of the ordinary ray in passing from the first prism into the air space.

Mr. Madan said no doubt there was a loss of light in this case; but this was a disadvantage which the prism suffered in common with Foucault's and other prisms. Something must necessarily be sacrificed to obtain greater advantages in other directions. He thought that as regarded light Bertrand's was certainly more effective.

Mr. Dowdeswell exhibited some septic microbes from high altitudes, and detailed experiments as to Bacterial germs found at various heights, notably upon the Niesen, at an elevation of about 7,500ft.

The President regarded every addition to their knowledge in this direction as being of the utmost value, and remarked that everything pointed to the necessity of a thorough working out of the correlation of the whole of the specific forms. When that was done they would have gone a long way nearer towards the solution of the problem of their connection with epidemic disease.

Dr. Maddox said he had been in correspondence with M. Freudenreich on this subject, and had obtained a specimen of the organism to which he had referred, and he could say from examination that it was only a septic organism and not a pathogenic form. Great pains had been taken in carrying out these observations, as would be seen from the fact that all the apparatus had to be carried up high mountains. It was found that the tubes originally provided could not be used conveniently, and he had therefore devised a form of bottle for the purpose, which would fulfil the required conditions, and be also portable. This bottle had a cap fitting hermetically over the neck, in which cotton wool was placed, and two tubes were provided for the purpose of aspiration and for removing the contents for cultivation. The time required for aspirating with a large quantity of air was also found to be inconveniently great, so that an apparatus of greater capacity was made on the principle of a steam injector, which was capable of throwing nearly 2,000 litres of air in an hour. By means of a diagram the method of charging the cultivation tubes with the contents of the bottle was explained, and the use of a small captive balloon was suggested as likely to be of great use in insuring the purity of the samples of air obtained from given localities.

Mr. J. Mayall, jun., reverting to the model of the old microscope exhibited by Mr. Crisp at an earlier period of the meeting, asked if there was any means of fixing the date when it was made, as he thought it would be very interesting if they could do so with certainty.

Mr. Crisp said there was no difficulty in fixing the exact date. Agreeing in the suggestion of Mr. Madan that it was much better to see a thing in the flesh than in a drawing, he had last month ordered one to be made, and it was delivered that night. The workman deserved all credit for the skilful manner in which he had manufactured so deceptive a piece of antiquity, even the paper on the drum was 200 years old.

Mr. A. D. Michael gave a summary of his paper on "New British *Oribatidæ.*" He first called attention to the nymph of *Cepheus bifidatus*, which he has just discovered; the species is very rare, and the immature stages were not known. Last September, at Keswick, Mr. Michael found two or three specimens, and instead of preserving them as examples determined to try and breed from them. He isolated them, and after some weeks obtained a few eggs, from which he reared four larvæ; these he has carefully watched for six months, until they had changed to nymphs and become full-grown; he then killed and preserved two specimens of the hitherto unknown nymph, reserving the two others to rear to the imaginal condition. One was lost by an accident just before the final change, the other lived. The nymph, which was exhibited, was a very remarkable and beautiful creature, surrounded with concentric rows of curved serrated spines longer than the body. Mr. Michael then called attention to a new species of *Hypocthonius*, proposed to be called *H. lanatus*. The ordinary definition of an *Acarus* is an eight-legged arthropod without segmentation, and with head, thorax, and abdomen fused into one mass. Really in the *Oribatidæ*, and several other families of *Acarina*, the abdomen is distinctly divided from the cephalothorax, and in this genus, which has been erroneously supposed to consist of immature creatures, the abdomen is segmented, and in the present species the segments are to a certain extent retractile, as in many insects; this enables the creature to erect, or lower, the long spines attached to the edges of the segments at will. An interesting new species to be called *Notaspis serratus*, abundantly provided with long serrated hairs, and a curious nymph of a Damæus, to be called *D. tenuipes*, which carries its cast dorsal skins in a pyramid on its back, like a pile of dish-covers, and has a central projection on each skin, forming a column to support the whole, were also shown and described, besides other new species.

Mr. Crisp called attention to some very interesting experiments by Dr. Nussbaum and Dr. Gruber on the artificial division of infusoria. Dr. Nussbaum divided an *Oxytricha* into two halves, either longitudinally or transversely, and found the edges at the point of division were soon surrounded with new cilia. Notwithstanding that sometimes some of the body substance, or even a nucleus, was lost during the operation, the two halves became normal animals, with four nuclei and the characteristic ciliary apparatus. The head portion formed a new hinder part, and the right half a new leg. The complete organisms thus formed again developed by spontaneous division. Simultaneously with Herr Nussbaum's experiments Dr. A. Gruber artificially divided *Stentor cæruleus* with the same results. If the divided parts of a *Stentor* were not completely separated they almost tore themselves apart, sometimes by rotating in opposite directions. If the cut was not very deep monstrous forms might be produced, as, for instance, with two complete anterior or two posterior portions.

Mr. C. H. Kain's letter was read as follows: "In the report of the last meeting of the Society, given in the ENGLISH MECHANIC of Jan. 23rd, I notice that a note from Dr. Gray was read, warning members against the use of tolu as a mounting medium on account of its tendency to form crystals. I believe I was the first to call attention to tolu, and therefore it may not be inappropriate for me to say a word. At first I had the same difficulty as Dr. Gray. Indeed, styrax is also likely to produce crystals. There is, however, an easy way of obviating the difficulty in the case of tolu—viz., by dissolving out the cinnamic acid. Tolu is not soluble in benzole; but cinnamic acid is. I have found that by digesting the coarsely powdered gum in benzole for a few days the cinnamic acid is removed. After pouring off all the liquid possible, fresh benzole should be added and allowed to remain a day or two. After pouring off this, the rest of the benzole should be evaporated, and the tolu then dissolved in chloroform and filtered; it is then ready for use. It is best to use heat in mounting, so that, when finished, the medium is nearly, or quite, hard. The greatest objection to the use of tolu is its colour. By this mail I send you three slides of *Navicula rhomboides* (and *Tabellaria fenestrata*) mounted respectively in Canada balsam, styrax, and tolu. That in tolu was mounted October 11th, 1884, and fails to show any signs of crystallisation as yet—indeed, I have had no difficulty with crystals since using the process I have mentioned.

Mr. Crisp referred to some of the differences of opinion having arisen from the different meanings which were attached to the term, benzole. What was here understood by that name appeared to be different from the substance so called in America.

Mr. Michael said he had been trying experiments with some of these substances lately, and perhaps could throw a little more light on the matter. He found that there was a great deal of difference in the gums, and that different samples, obtained from perfectly reliable sources, acted very differently under similar conditions. One sample of styrax, for example, would dissolve perfectly in benzole, whilst another would not do so. He thought this might also be the case with some others; but if the tolu was prepared carefully by boiling in distilled water, to get rid of whatever acid it might contain, he believed it might be reduced to a state in which it would give very little trouble afterwards by crystallisation.

Mr. Crisp called attention to the alteration of the contents of the Journal, which now contained the names of all the authors. The credit of this was due to Mr. Walter Heape, of Cambridge, and he thought the alteration would be found an obvious improvement in facilitating reference to any paper. He had also taken the opportunity of adding the headings of the classification, and had also included all the papers of the bibliography of which any abstract was given, as he found these were often passed over unnoticed.

Mr. H. Mills's note was read as follows:—

I send six slides of *Stephanodiscus Niagaræ*, showing filamentous projections on the margin of the diatom. During the last ten or twelve years I have given attention to the examination of these organisms, but am still at a loss to determine what they are, or the purpose they serve (if any) in the economy of the diatom. If found attached in the same manner to any of the diatoms that have motion, we might conclude at once that they were for the performance of that function, but occurring as they do on these discoids, which have no motion, it is difficult to suggest anything that is probable. We find many of the diatomaceæ in our water supply, none, however, having these attachments; but *S. Niagaræ*, and perhaps a few *cyclotellæ*, or other small discoids. The *S. Niagaræ* are found in great abundance during the winter months, and for several years past I have found the filaments most abundant in January, at which time the diatoms can be taken almost free from foreign matter. The past January has been unusually stormy, and the water consequently roily, while the filaments are not as well developed as in some former years. Five of the slides are mounted dry, as the filaments, with rare exceptions, cannot be seen in water. Slide No. 6 contains a drop of water with the diatoms, as caught from a small stream from the faucet in a muslin bag. The extreme tenuity and hyaline character of the filaments are the greatest hindrance to a more perfect examination of them. They are seen to best advantage with a strong light and dark background illumination; sunlight adding much to the effectiveness of the observation. In slide No. 1, using ¼in. or ⅙in. objective, may be seen how regularly the filaments arrange themselves on the slide; frequently those of one diatom crossing those of another, all maintaining a radial position with some degree of preciseness. This fact alone would indicate a substance very different in character from the mycelium threads of an ordinary fungus. When the diatom is examined edgewise—that is, in front view—the filaments can be seen to proceed from near the line of suture, but whether from the internal contents of the frustule or from the ring of the diatom I am unable to determine. If from the ring I have thought they might be silicious, although recent experiments show that they are consumed by the heat of an alcohol lamp. A drop of water containing a few of these diatoms placed on a slide and allowed to evaporate under the microscope is interesting, and displays a phenomenon not shown by other diatoms that I am aware of. As the line of evaporation proceeds on the slide, the diatoms frequently disappear instantly; in some cases leaving the filaments attached to the glass, while in other cases, where there is but little foreign matter to interfere, they may be found beyond the extent of the drop, with the filaments spread out as radially as if placed so artificially. If the diatoms stand long enough for the water to become sour, the filaments fall off, and may be seen scattered about the slide, as in No. 2. In some of the slides may be seen a few small discoids without spines, which, when alive in the water, seem to possess power to repel every light body from contact with them, so that a distinct transparent annulus as wide as the diameter of the diatom is presented. A little blueing placed in the water under the cover glass makes this more noticeable (see *American Monthly Microscopical Journal*, Vol. II., page 8, 1882.) *This year* I have noticed for the first time that these small diatoms when dry have several short projections which, if in motion, would seem to be sufficient to form the annulus. In some cases the long filaments of *S. Niagaræ* have the appearance of being branched. My opinion is that it is merely an overlapping.

Mr. Badcock said Mr. Mills's specimens were different from those which he had exhibited on a former occasion as occurring upon *Surirella bifrons* at Keston. These appeared to him to have a distinctly pseudopodal character, having movements very much like an amœboid elongation and contraction, whereas these now shown very much resembled the setæ of *Actinophrys*. The question in both cases was whether they represented animal life as being prolongations from the inner protoplasm. So far as their appearance on the slides was concerned they might possibly be foreign bodies.

Mr. Hardy said that he had some of the specimens of *Surirella* taken at Keston, and had observed them quite independently. He was not able to see that they had any motions, and could say that they were certainly not sarcodic forms.

Dr. Wallich said there was a complete analogy between the specimens now shown and some which he exhibited about 20 years ago, to which he gave the name of *Coscinodiscus Sol*. He found his specimens in the Indian Ocean, and they were described and figured at the time in the Society's Journal.* In the case of the Keston diatoms he took them to be Epizoa, and thought that Mr. Hudson, writing from Australia, referred to precisely the same forms; but they were also distinctly epizootic. In the case before them, there was no question in his mind about their being a portion of the animal itself, there being distinct apertures round the valves from which they were given off. He was now engaged in going over the slides which he presented to the Society, and found that all these specimens were amongst them still.

Mr. G. C. Karop remarked on an examination he had recently made of the saliva in a case of hydrophobia. The patient, a boy 12 years old, had been bitten two months before any symptoms appeared. He was then brought to the Middlesex Hospital, where he died the day after admission with all the usual symptoms and agonising tortures of this horrible disease. An attempt to administer chloroform was made during one of the violent paroxysms towards the end of the case, and about two drachms of saliva collected in a clean tube as it dribbled from the mouth. Some covers were prepared in the usual manner, stained with gentian violet, and mounted in xylol-balsam. The specimens presented the following characters:—Epithelium in large quantities, most of the cells crowded with micrococci; bacilli of various lengths, and very variable in diameter, some being thick and others extremely slender. A few showed evidence of spore formation, and were surrounded by a capsule. Micrococci abundant, in masses, diplococci, and short chaplets. Mr. Karop also exhibited a drawing of the Bacilli.

---

* *Transactions* of the Society, 1860, plate 2.

Mr. J. Mayall, jun., exhibited the diamonds belonging to the ruling machine of the late F. A. Nobert, a typical one being shown under the microscope by Mr. Powell. He said that in engaging to report to the society the results of his examination of the ruling diamonds, he had expected the task would involve at the most a few hours' work with the microscope, using powers from 20 to 150 diameters. In this expectation he had been mistaken; he had not found it possible to explain the nature of the diamond surfaces by mere inspection with the microscope. On calling in the testimony of "experts" in diamond cleaving, polishing, &c., the results arrived at had become still more complicated—one party affirming that certain surfaces were polished, whilst the other insisted that they were cleavage faces and *not* polished—so that he (Mr. Mayall) had almost despaired of the possibility of bringing before the Society a report to which he could pledge himself. There were ten diamonds with the machine. Two of them were technically termed "points," pyramidal fragments of diamond terminating in points, and all who had examined them agreed that one was a piece of natural crystal, whilst the other had two cleavage faces and one crystalline (natural) face, all three faces untouched by the mill. Regarding these "points," there had been no difficulty in deciding that *none* of the surfaces had been polished. The other eight diamonds each presented the general form of two faces meeting in an "edge"; the difficulty had been to decide whether the faces were in some cases (1) both polished, (2) both cleaved ("cleavage faces" unpolished), or (3) one polished and one cleared. The opinions of the diamond experts could not be reconciled, for in two instances they were in absolute contradiction; one party affirming that both surfaces were polished, whilst the other party were equally positive that both surfaces were due to cleavage, and were *not* polished. Under these circumstances it had appeared to him essential to submit the surfaces to the test of the goniometer, with a view to determining whether the angles of the natural cleavage planes had been altered, any such alteration being necessarily due to artificial polishing of one or both surfaces. He had thought it would be most satisfactory to ask the assistance of a professional mineralogist, and had therefore applied to Mr. Lazarus Fletcher, of the Mineralogical Department in the British Museum, who had very kindly undertaken to examine the diamonds, and measure the angles with Fuess's goniometer. In Mr. Fletcher's opinion the two "points" were untouched by the mill; diamond No. 4 consisted of two cleavage faces meeting in the edge, and was untouched by the mill; in all the other cases *one* of the faces meeting in the edge was an untouched cleavage face and the other had been polished, and in some cases an additional facet or two developed on that side: the alteration of the cleavage-angle he regarded merely as an incident of the polishing. *En résumé*, there were seven diamonds, each having two principal faces meeting in an edge, one face in every case being an untouched (unpolished) cleavage face, whilst the other was polished; one diamond had two cleavage faces meeting in an edge, and both faces were untouched (unpolished); the remaining two were "points," not touched by the mill. The goniometer showed that in the polishing the angles had been altered from the natural cleavage planes by quantities varying from a few minutes up to about six degrees, and as no two were exactly alike it might be assumed that, as Mr. Fletcher suggested, "the alteration of the angle is merely an incident of the polishing," and not a condition distinctly aimed at by Herr Nobert. Mr. Mayall said that, in the face of Mr. Fletcher's opinion, he must withdraw the statement he had made at the previous meeting that some of the diamonds appeared to have two polished surfaces meeting in one edge. On closer examination in Mr. Fletcher's presence, he found that certain striations on the surfaces which he had regarded as imperfectly polished were more probably untouched, and therefore he now gave his adhesion unreservedly to Mr. Fletcher's judgment. Regarding the mode of preparing the ruling diamonds adopted by Herr Nobert, Mr. Mayall said he had no record save the diamonds themselves. The matter could only be decided by conjecture. After various consultations with diamond experts, he had come to the conclusion that diamonds, exhibiting under the microscope precisely the character of the seven "edges" to which he had referred, could be prepared from the fragments of gem diamonds met with at any diamond cleavers. The cleaver would select a fragment which would admit of two faces being cleaved to an edge of about $\frac{1}{18}$in. or $\frac{1}{20}$in. in length; one of these faces should be perfectly polished on the mill as near as might be parallel with the cleavage face; the other face should then be cleaved again parallel to its former cleavage, so as to remove the edge, which would probably have been somewhat rounded by the mill, thus furnishing a new and probably sharper edge—a clean fractured surface meeting the flat polished surface; the diamond should then be mounted in soft metal in a notch at the end of a piece of brass wire by means of a blowpipe. Such fragments of diamonds had but little commercial value. A diamond cleaver in Antwerp had estimated the cost of supplying them complete at less than ten shillings each. After referring to the various notes on the diamonds contained in Herr Nobert's memorandum-book, Mr. Mayall said he had no doubt the publication of the data obtained from the examinations of the diamonds would further the interests of micrometry. Several ruling machines existed both in Europe and America capable of dividing space as minutely and exactly as Herr Nobert's machine; but most, if not all, of them refused to rule lines at all comparable to Nobert's when the closeness exceeded about 50,000 to the inch, and this was, he believed, mainly, if not wholly, due to imperfection in the diamond, or in the method of regulating its pressure upon the surface to be ruled.

Mr. Hardy exhibited a colony of *Vorticelli* having the stalks agglutinated in a bundle, and covered with transparent gelatinous matter. It was found erect on leaves in colonies of 50 to 100, some more erect than others, and coming off the leaf freely. When loose, they appear very like large *Conochilus*, but sink by the weight of stalk. The body was campanulate and very slightly retractile. Hight, 2mm. to 4mm.

Mr. Cheshire exhibited a remarkable slide showing conductive nerve threads escaped from the sheath of the ganglionic chain running through the first three segments of the abdomen of *Vespa vulgaris*.

## LIVERPOOL MICROSCOPICAL SOCIETY.

The ordinary monthly meeting was held on Friday, at the Royal Institution, the President, Mr. Chas. Botterill, F.R.M.S., in the chair. There was a large attendance.

The minutes of the previous meeting were read. Messrs. T. J. Lloyd, L.D.S., and A. Codd were elected members of the Society.

Mr. J. C. Thompson referred to the loss sustained to microscopical science through the death of Mr. Charles Vance Smith (son of the Rev. Vance Smith, of Carmarthen), who, though paralysed for many years, had attained a high position among microscopists, through his delineation of the microscopical structure of plants.

The Rev. H. H. Higgins, M.A., called the attention of members to the importance of observing and recording any variation of species, together with the conditions under which such variations occur, with the view of further advancing microscopical and biological science.

Mr. A. Norman Tate, F.I.C., then read the paper of the evening, on "The Microscopical Examination of Potable Water." After alluding to the impossibility of always determining by chemical means alone whether a water is, or is not, fit for dietetic purposes, he proceeded to speak of the importance of microscopical investigation in relation to water supply, pointing out that it afforded better opportunity of determining the character of organic impurities, and that it might frequently assist in ascertaining the character of the mineral constituents. He considered the arbitrary standards of purity as regards organic constituents, set up by some water analysts as being unsafe to use, without knowing the exact nature of such matters And in deciding this the microscope could help. He then proceeded to speak of investigations concerning the minute animals and plants in waters contaminated with sewage, &c., and then described different modes of collecting and examining waters microscopically, and urged the importance of further investigation, so as to ascertain how far the organised matters present in water are capable of developing disease, and how such organisms may be destroyed by various means, describing several modes which might be adopted in carrying out such inquiries. In conclusion, he mentioned impurities found in natural ice, and also two methods of examination of rain and air.

A discussion followed, in which the Rev. H. H. Higgins, Mr. Davies, and the president took part, and a cordial vote of thanks was passed to the lecturer.

# SCIENTIFIC NEWS.

The death is announced of Prof. Carl von Siebold, the eminent physiologist of Munich, where he had long been Professor of Zoology. He was in his eighty-first year.

Mr. Frederick Field, F.R.S., the senior partner in the firm of J. C. and J. Field, and one of the original members of the Chemical Society, is also dead. He was at one time Professor of Chemistry at St. Mary's Hospital, and filled a similar post at the London Institution. Mr. Field contributed numerous papers to chemistry, and penned many valuable notes on the mineralogy and metallurgy of South America, the facts of which he gathered during the time he held the office of Vice-Consul at Caldera, in Chili.

We have received the report of Commodore Franklin, Superintendent of the United States Naval Observatory, giving the usual account of the work done at the Observatory, Washington, by the different officers, and with the various instruments. The superintendent reiterates the suggestion of his predecessor, that there should be appointed annually a Board of Visitors, to consist of a small number of scientific men, whose duty it should be to examine into the conduct of the Observatory, and make such suggestions as might add to its general usefulness. From the programme of work to be pursued this year, we find that amongst other tasks allotted to the 26in. equatorial will be observations of the conjunctions of the inner satellites of Saturn during the opposition of the planet, and a complete micrometrical measurement of the dimensions of Saturn's ring. Three drawings of the planet will also be made—one before opposition, one at, or near, opposition, and one after opposition. Observations of a selected list of stars are to be made with the prime vertical transit instrument in conjunction with the Royal Observatory, Lisbon, for the determination of the variability of latitude.

The Académie des Sciences of Paris offers for the present, and three following years, a medal of the value of £120 for some important improvement in the theory of the electric transmission of work. The Bordin prize of £120 is also to be given for the best memoir "On the Origin of Atmospheric Electricity and the Causes of the Great Development of Electrical Phenomena in Storm Clouds." The memoirs must be sent to the secretary of the Academy before June 1, in the year in which they compete.

The grounds of the New Natural History Museum, at South Kensington, will shortly be opened to the public, who will be admitted from the subway now being constructed along the Exhibition-road. The collection of fishes, insects, and British zoology will probably be ready for inspection by the next Bank Holiday; those collections in the new buildings already open were visited on Easter Monday by numbers far beyond expectation.

In a paper contributed to *La Houille* on explosions of firedamp and barometric falls, M. de J. Lebrun throws a doubt on their connection. He says that several English engineers and men of science have sought to establish a coincidence between great barometrical depressions and explosions of firedamp; but an inspection of the tables published by the French Commission on Firedamp does not appear to prove this. There are as many explosions at moments when the barometer does not vary and when it rises as there are when it falls.

An electrical railway is in course of construction at the Alexandra Palace, leading from one of the gates to the building itself, so that visitors will be able to avoid the up-hill walk from the entrance.

The annual meeting of the Iron and Steel Institute will be held in London on May 6 and two following days. Dr. Percy is the president-elect, and will deliver an inaugural address on the first day, which will be followed by the reading and discussion of eleven papers, some of which will certainly be taken as read. Two of them deal especially with the coke-making process known as Simon-Carvès, which is now adopted to a considerable extent in the North of England; and a third paper, by Mr. I. Lowthian Bell, will inform the public of the value of such coke for iron-making purposes, as ascertained at the extensive works in the Cleveland district, of which that gentleman is the head. Three papers will deal with the subject of steel in relation to its manufacture and its properties. The first of these, by Sir Henry Bessemer, is likely to cover the ground of the manufacture of steel generally, and will probably show the fitness of Bessemer steel for many purposes. Another paper, by Dr. Sorby, F.R.S., of Sheffield, will illustrate the microscopic structure of steel; and a third paper, by Dr. H. Wedding, of Berlin, will afford information as to the mechanical properties of steel, based upon investigations made by that gentleman in Germany. Mr. Andrew Carnegie sends a paper on "Natural Gas, and its Utilisation for Manufacturing Purposes in the United States"; and steel makers and shipbuilders will be interested in a paper promised by Mr. Parker, of Lloyd's, on "The Causes of Failures in Steel-plates." The Bessemer gold medal for 1885 will be presented to Professor Richard Akerman, of Stockholm.

A locomotive has been recently completed for one of the Brazilian lines by the Baldwin Locomotive Works, Philadelphia, which is the second largest ever built. It is to run on a gauge of 5ft. 3in., and has cylinders of 22in. diameter by 26in. stroke. The driving wheels are 3ft. 9in. in diameter, and are coupled to four other pairs—hence the type is called "Decapod." A pony swing truck leads. The total wheel base is 24ft. 6½in., of which 16ft. 11½in. is covered by the drivers; but the rigid base is only 12ft. 7½in., the second and third pairs of wheels being without flanges. The boiler is straight, 5ft. 4in. in diameter, with copper firebox, and 268 2in. steel tubes. The firebox is 10ft. 1in. long by 39½in. wide, and the total heating surface is 1,940 square feet. The tractive force is 279 pounds for every pound of effective pressure on the pistons.

According to the *Railroad Gazette*, the longest train ever seen on the Lehigh Valley road consisted of 123 eight-wheeled coal cars, all loaded, and it was drawn by a single engine. An extraordinary engine, or perhaps some mistake in the number of loaded coal waggons.

According to Dr. Korab, writing in a Spanish pharmaceutical journal, Helenina, the principle of Inula Helenium, has powerful antiseptic properties. It is sufficient to use it in the proportion of 1 to 10,000 parts to preserve very putrescible fluids. An egg, beaten up with about 10oz. of water, and treated with five grains of helenina dissolved in about 30 grains of alcohol, remained perfectly sweet for six days at a temperature of 82° Fahr. Dr. Korab has made many experiments, and has found that helenina destroys organisms in infusions, and the aroma of the drug keeps away mosquitoes. It is valuable in surgery, and has been used in medicine with advantage. Whether the common elecampane of this country will yield a drug as potent as the Spanish remains to be seen.

## USEFUL AND SCIENTIFIC NOTES.

**Preparation of Absolute Alcohol.**—Dr. Sharp states that absolute alcohol is prepared in Ranvier's laboratory by adding anhydrous cupric sulphate to 95 per cent. alcohol. Pulverised cupric sulphate is heated to red heat in order to drive off the water of crystallisation; when cool the white powder is placed in a wide-mouthed bottle, holding about a litre, and three-fourths full of alcohol. The bottle is quickly closed and the whole shaken. After standing a day or more—with occasional shakings—it is decanted and the operation repeated, especially if the cupric sulphate shows much of the blue colour due to the reassumption of water. As a test, a drop of the alcohol thus dehydrated may be mixed with a drop of turpentine on a glass slide, and examined under the microscope; if no particles of water are to be seen, the alcohol is absolute enough for all practical purposes.

**Mercury as Ballast.**—Some members of the New York Yacht Club propose to use as ballast, during the coming season, flasks of mercury. The idea that liquid ballast will aid a vessel's progress by the impact of its swaying is very widespread, and was certainly in vogue many years ago, as Lord Nelson is said to have used it in naval operations by fastening casks of water from the mainstay for the purpose of increasing the speed of the vessel. Mercury would form a superior ballast, as its heaviness would reduce the centre of gravity of a yacht lower than an equal weight of lead or iron, but it seems strange that its liquid state should credit it with some latent means for augmenting the speed of a craft.—*Engineering.*

# LETTERS TO THE EDITOR.

*[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]*

*All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

*All Cheques and Post-office Orders to be made payable to* J. PASSMORE EDWARDS.

⁂ *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks a vice from whence great inconveniences derive their original."
—*Montaigne's Essays.*

### HYPERION AND DOUBLE STARS.

[24100.]—I AM much obliged to Mr. Sadler for his elaborate reply *re* $\theta$ Aurigæ and Hyperion. I must accept his decision that I did not see Hyperion, but a faint star in its exact position. I am glad he has given such full particulars of apertures with which only it has been seen. But is there any suspicion existing as to its variation? The satellites of Saturn, which are easily visible to me, are, in my opinion, all variable in lustre.

I see in his data of $\theta$ Aurigæ the mag. of the close *comes*, as established by $\beta$. in 1878, is much smaller than by O.$\Sigma$. in 1870. $\beta$. is certainly right, for this very fact of its smallness threw me out in looking for it. I was looking for a much brighter *comes*, and was astonished when I found it so minute. I think Mr. S. will find the notices of this star he refers to in 1883 do not refer to the *comes* at all.

As to O $\Sigma$. 175, I saw it well divided, March 30, with 400 $\pm$; and $\omega$ Leonis also, with same power.

In Horne and Thornthwaite's "Hints," $\alpha^2$ Cancri is given as a test object. Webb does not mention it, and Proctor's maps only show $\alpha$ and not $\alpha^2$. What does the small 2 mean? The R.A. and D. is correct for $\alpha$ Cancri. I should like to propound a query as to under-corrected mirrors. I believe most mirrors are left slightly under-corrected —that is, the central focus is longer than the marginal. Now, the focus of a convex lens, uncorrected for spherical aberration, is just the same, and of course the focus of a concave lens uncorrected will be shorter for central rays—that is, the aberration is in opposite direction. If, then, a Barlow lens be made achromatic, but with a small residuum of spherical aberration, it will correct the under-correction of mirror, and will allow of an exact balance being obtained by moving it to and from the speculum. Its compensating power would be greatest when most within the focus, diminishing to nothing at the focal point. I think the performance of many slightly under-corrected mirrors might be made practically perfect by this means.

**Edwin Holmes.**

### VISIBILITY OF THE 5th AND 6th STARS IN THE TRAPEZIUM OF $\theta^1$ ORIONIS, &c.

[24101.]—MR. SADLER, p. 298, Vol. XL., asks me for dates on which I have seen the 5th and 6th stars in the Trapezium with a 3⅜in. refractor. The occasion to which I referred at Port Macquarie was on the evening of 25th November, 1882, $\theta^1$ being at an elevation of about 60°. On subsequent occasions I have kept no record of dates.

The telescope has really a trifle less aperture than I have named, the setting of the o.g. reducing it to 3.65in., clear focal length 57in., altazimuth stand. The o.g. is of excellent quality, giving a perfect picture of a star disc under the highest power.

Mr. Sadler is quite right in his supposition of the misprint referred to in the concluding portion of his letter.

Sydney, N. S. Wales. **G. D. Hirst.**

### SATURN.

[24102.]—I HAVE lately mounted for myself a splendid 6¼in. Calver mirror. The definition and ease in observing has surpassed my expectation; and I would like to ask those in possession of larger instruments if Encke's division has been seen on Feb. 7 and 18 and March 1 and 14 of present year? On Feb. 17, at 9.45 p.m., the definition of Saturn was very bad with a high power, so I used a low-power eyepiece, and had not been observing long when a beautiful meteor passed through field of view. I reckoned the curve was from 147° to 302° in eyepiece. I could not see any "tail," neither was it visible to the naked eye, as I looked for it directly. I write this merely as a curious incident. Can any of "Ours" give a few tests for the above? I find, in looking at $\xi$ Majoris, given as a test for 4in. o.g., I divorce this double with 200, very wide. I would like naked-eye tests.

**Aleph.**

### $\theta$ AURIGÆ.

[24103.]—IN consequence of the interesting letter (21065) dated February 10, 1883, of your correspondent, Mr. Sadler, I carefully looked at $\theta$ Aurigæ with my 8in. equatoreal. I find in my note book, under date April 2, 1883, the following:—"Could not make out Sadler's companion at about 170° and 50″; distinctly at times, saw his other at about 340° and 50″; also saw the other distant one at about 270° and 150″." I tried Mr. Sadler's faint star at about 170° 50″, with all powers, but utterly failed to see it. With this exception, I had no difficulty in seeing all the others mentioned by Mr. Sadler in his letter (24064) in your last week's number. I am strongly of opinion that, at least, to my eye and instrument, the close companion (B) is much more difficult than it was in 1881, when I could see it well with powers from 350 to 500. I hope to examine this group again, and if successful with Mr. Sadler's companion, which I missed in 1883, to report in your pages.

**George Hunt.**

Hopefield, Alleyn Park, West Dulwich, April 13.

### PRESERVATION OF THE MIRRORS OF REFLECTORS—FRESH WATER AND SALT — SMOKE — SUNSPOTS AND THEIR PERIODICITY—NORWEGIAN LOBSTERS.

[24104.]—WITH reference to Dr. Royston Pigott's footnote on page 118, Vol. XLI., I am quite unaware of any method of preserving the silver films of reflectors, and should be very glad to hear how it is done, if any reader could spare time to inform me? I had the ill luck to miss nearly a year's ENGLISH MECHANICS, so perhaps it has already been referred to. If the process really preserves the film, it would go a long way towards making reflectors suitable for day use; but I am still rather doubtful of the adjustments in uneducated hands.

Can anyone say by what laws fresh and seawater mix? Here, at the mouth of the Tyne, I often observe on fine days that the turbid current of the river, on leaving the piers that confine it, turns away to the north nearly at a right angle, according as the tide is running, and then forms a very distinct brown ribbon, which keeps its original breadth, or at least spreads out very little, and gradually grows fainter and fainter (I suppose as the mud held in suspension is deposited), till it disappears some miles away at sea. Now, no doubt, fresh water is lighter than salt, and should therefore float on its surface; but, if it really does so, I cannot see what prevents it from spreading laterally, as, to float on the sea at all, implies to be on a higher level than the sustaining fluid. Does cohesion come in, or what is the force that retains this brown ribbon of water within fixed limits? It is a most remarkable sight on a fine day, when the sea is calm and the wind in the east. With a wind from the south-west there is a much more explainable and unpleasant phenomenon—namely, the coming down of a vast cloud of smoke from the river and Newcastle, which fills the air with smuts, and blots out the sea and the sun. If I were a member of the Statistical Society, I might amuse myself in calculating how many millions of foot-pounds of energy were daily disappearing in the form of smoke; but as such a computation would have no very practical effect, I forbear. With coals at 12s. a ton, human nature will not consider the future.

There have been splendid groups of spots on the face of the sun during the present year. I confess myself wholly unable to trace the 11-years period, though I am ready to believe in it on authority. But the activity of the sun's envelope should be very visibly decreasing now, and yet I have only once this year seen its face pure of spots. And I generally look out every fine morning.

Is the small Norwegian lobster known at all in the South of England? It is a cheap and pleasant article of food here and in Dublin. In both places the inhabitants call them "prawns."

Tynemouth. **Garrison Gunner.**

### THE ROYAL ASTRONOMICAL SOCIETY'S "MONTHLY NOTICES" FOR DECEMBER, 1884, AND MARCH, 1885.

[24105.]—MAY I be allowed to call the attention of your readers to the very interesting character of the information contained in the above-mentioned periodicals of the dates referred to? If your many amateur readers fail to possess themselves of a valuable amount of knowledge by their perusal, it must be their own fault. They will find, in the latter number, a mass of figures extending from pages 348 to 373 inclusive (i.e., 27 pages), which would take them twelve months' hard toil to decipher, and more than that period properly to appreciate. But if not satisfied with that, they may turn their attention to a chronicle of figures embodying "spectroscopic results for motions of stars in the line of sight obtained at Greenwich," which must be equally fascinating to anyone who can revel in 13 pages more of closely-printed figures. Add to this, there is a well-assorted list of "Notes and corrections to Sir W. Herschel's Memoirs," most instructive and agreeable to all who delight in Sir John Herschel's valuable synopsis. But some more excellent reading is obtained on reference to the 17 pages (pp. 298-316) touching the star-places in the *Nautical Almanac*. The portions of the December number which are so valuable to those who have leisure to visit the Cape Observatory will be found in the 22 pages wherein are discussed the "Systematic Errors of the Cape Transit Circle," for possibly they may learn by this means how to regulate their own instruments at home, if only they have funds at their disposal for the purpose. **Amateur Astronomer.**

Preston, April 11.

## THE SOLAR DIFFRACTION SPECTROSCOPE AND STAR-SPECTROSCOPE.

[24106.]—I RETURN my sincere thanks to Mr. W. H. Haren for his full and lucid communication regarding the construction of the solar diffraction spectroscope. Through information which comes to me from various sources, I am satisfied that his letters on this subject have aroused the interest of many amateur workers, several of whom will assuredly construct instruments upon the principle he has described. Shortly after Mr. Haren had first drawn the attention of our readers to this interesting subject, I procured a grating similar to the one he is using, and, aided by some hints from our kind and ever-obliging friend, Mr. Brashear, mounted it for experiment in a simple way at first, deferring the construction of a more perfect instrument till I could have the benefit of the fuller instructions which Mr. Haren has since so obligingly furnished. Even with the rough and imperfect model above mentioned, my experiments were most satisfactory; the results quite surprising me. I hope before very long to have completed a properly made spectroscope for this admirable grating, which, indeed, deserves the best and most careful mounting.

In reply to Mr. Edwin Holmes (letter 23848, p. 539), I beg to say that in reciting some of the "other" applications of a small star spectroscope, I fear I shall only be enumerating uses with which he and others are already quite familiar. However, as he puts the question, I may mention that an instrument such as he has constructed will show not only the spectra of stars and nebulæ, but those of the planets also. Doubtless before this, Mr. Holmes has tried his spectroscope on Jupiter and Saturn. In the brilliant spectrum of the former, the dark lines are beautifully shown without a slit, while in the fainter light of Saturn many lines are still visible. No doubt comets would give interesting spectra, though here I do not speak from experience. In connection with all these objects, the hints relative to comparison of spectra given in Browning's "How to Work with the Spectroscope" might be turned to useful account, and would probably be fruitful of interesting results.

Then removing our cylindrical lens and substituting a slit and collimator—adding, too, if possible, a small observing telescope, we are ready to examine and study the lunar spectrum, and, to a certain extent, that of the sun. In this latter the bright lines of the prominences may be readily seen by a little management.

It seems needless for me to speak of the suitability of our modified instrument for exhibiting the simpler chemical and absorption spectra; but I may say that a small equilateral prism fixed over half the slit is an addition readily made, and one which renders possible with very simple means some interesting comparisons of dark solar lines with those of terrestrial elements. Nor should the auroral spectrum be forgotten; nor the study of those atmospheric lines which give to the spectroscope its value in meteorology. In fact, the possessor of a small instrument, such as Mr. Holmes's, may constantly turn it to use in one way or another with results which, though trivial to the possessors of powerful batteries of prisms, are most interesting and instructive to the amateur worker who is contented, or even delighted, if his experiments be moderately successful. The student unprovided with instruments may peruse half a dozen volumes treating of dark lines, bright lines, and so forth with but a partial understanding of the significance of what he reads; but let him *see* these things once, and I doubt not he will find he has thus acquired a far deeper and truer insight into his subject than he could ever have gained by reading only.

I regret my inability to aid Mr. Holmes with advice as to the best form and position of the cylindrical lens. Doubtless, some of our optical correspondents can assist him. So far as my very limited experience reaches, I believe that convex cylindrical lenses are used conjointly with slits, being placed at some distance in front thereof. Lockyer and Schellen, however, found advantage to result from placing the lens in the path of the rays just before the eye receives them. In the McClean star-spectroscope the lens is, for obvious reasons, concave and situated close in front of the compound prism. Neither do I know of any means for separating the spectra of double stars other than by the use of a powerful telescope of long focus, and, of course, a slit-spectroscope. Mr. Holmes' idea in this direction was ingenious, but he could hardly expect it to succeed, except possibly in the case of two stars much more widely separated than the components of γ Andromedæ, and it would also imply great care in the focussing and other adjustments.

On p. 378, Vol. VIII. of the "E. M.," appears a device for showing star-spectra; but its action is not at all clear to me, since it is stated to consist only of a prism and a Huyghenian e.p. of high power. Still, as the arrangement purports to emanate from no less an authority than Dr. Huggins, it might be worth while to try it.

**A. F. Miller.**

---

## A 30-LIGHTER SERIES-WOUND DYNAMO.

[24107.]—THE following brief sketch of a dynamo put up by a friend of mine, which is doing excellent work, may be of interest to "Anglo-Dane," W. H. Eaves, and others who are thinking of erecting dynamos for private use.

While fully agreeing with W. H. Eaves as to the superiority of compound shunt winding wherever a varying resistance is likely to occur in the circuit, yet I feel that to amateurs the greater efficiency and easier make of the series-wound dynamo will ever make it a favourite. I cannot follow W. H. Eaves as to the jerking of the cog armatures; I can only say that I have never noticed such to occur.

The dynamo under consideration consists in a cog armature, 7in. diameter from cog to cog; thickness of ring, 1in.; outside diameter of ring (exclusive of cogs), 5¾in.; thickness of cogs, ½in.; depth of channel, ¾in.; number of cogs, 12; width of ring, 6in. Wire on armature, No. 14, double cotton-covered in six layers, about 70ft. to each channel, or 840ft.—say, 18½lb. The total resistance of this wire was 1·44 ohm, but the running resistance was only 0·359 ohm. The field magnets consist in two bars of cast iron, carefully annealed, slightly oval in section, being 4in. in the longest diameter by 3in. in the shortest diameter, the length of the wound portions being exactly 1ft. in each. These fit into two pole pieces of soft iron, bored out to receive the armature. When fitted, the pole piece is to form a cube 8in. high, 10in. wide by 5½in. deep. A heavy cross bar of cast iron is bolted to the top ends of the F.M.'s.

The field magnets are wound with 96 coils of No. 12 wire, seven layers deep, the entire length being about 1,680ft., or 63lb. The resistance in series was, as nearly as possible, 1·53 ohm, or about five times as great as that of the armature when running.

Driven at a speed of 1,400 revolutions, this little dynamo lights easily and well 30 20-candle power Swans. After a four hours' run, the machine was sensibly hot, but not too hot for the hand to bear. The E.M F. at terminals was 55 volts; the indicated current was 30 ampères. The dynamo is driven by a 2½ horse-power engine, which is certainly not overtaxed. **S. Bottone.**

---

## "ENGINE-MAKING AT HOME."

[24108.]—IN reply to "X." (letter 24093), the only objection which I see to the use of gas for small boilers is the expense. It does not follow that because gas is cheap when used as an expansive agent in engines, it would be cheap when employed for heating purposes. In the best-constructed boilers 1lb. of coal will evaporate 10lb. of water; but if we take the evaporative power of coal gas as equivalent to 1·31lb. of water per cubic foot of gas (given in D. K. Clark's Rules, Tables, and Data) 1,000ft. would be required to evaporate 1,310lb., being therefore the same amount of work which could be done by 131lb. of coal. But 131lb. of coal at, say, 8d. per cwt., would cost only 9 3d., against, perhaps, 3s. per 1,000ft. of gas. This is a good and sufficient reason why coal gas is not used in boilers. But I think, in an amateur's workshop, it would still be advantageous to employ the cleaner agent; not only as being cleaner, but for the reason that it can be quickly turned on and off. The lights could be arranged much as they are arranged around the interior of a cooking stove.

With respect to the second query, the reason why oscillating cylinders of the model-maker's type are not used for larger engines is, that there is no chance to render them steam-tight for any length of time. When the faces begin to wear, the steam must escape. Oscillating cylinders, to be serviceable, must have the points set in trunnions where the valve case can be furnished with stuffing boxes.

As to the rate of speed of a small engine with a pressure of from 10lb. to 30lb., you clearly cannot get more work out than you put in. The limit to speed is governed by the pressure, and the strength of the moving parts; 300 revs. per minute, is a high speed for small stationary engines; and, although locomotive pistons have a much higher rate of travel, it must be remembered that all the moving parts are very strong, and the steam of a high pressure—120lb. about. The only engines that reach 1,500 revs. per minute are the three-cylinder ones of the Brotherhood type, and then only those of the smallest bore. Steam of high pressure is used, and the pistons are not moved by a directly reciprocating rod, but by an eccentric. They run at a terrific speed, and are therefore used for dynamos and centrifugal pumps, where space is a consideration. This is the only kind of engine in which it would be possible to attain 1,000 revs. and more per minute. **J. H.**

---

## LECLANCHE BATTERIES.

[24109.]—IT may interest some of your readers, especially amateurs, to know how the above batteries can be made of an efficient character, and at a reasonable rate. The following gives the cost of a set I have just completed, having had a similar set in use for many months:—

| | | |
|---|---|---|
| 8 jars, Stiff and Sons, 85 A., at 6d. | 4 | 0 |
| 8 porous cells Stiff and Sons, 7 A., at 6d. .................. | 4 | 0 |
| 8 carbons, headed, Blackwell's, 6 × 1½, at 1s. ................ | 8 | 0 |
| 8 zincs, my own make, 8lb., at 5d. | 3 | 4 |
| 6lb. coke, Griffins, at 4d. ...... | 2 | 0 |
| 4lb. manganese, Griffiths, at 6d... | 2 | 0 |
| 5lb. sal-ammoniac, Blackwell's, at 8d. ......................... | 3 | 4 |
| Amalgamating zincs ............ | 1 | 0 |
| Connecting wires, solder, tallow, paraffin, sealing-wax, varnish, &c. ......................... | 2 | 4 |
| 8 cells, at 3s. 9d. each | £1 10 | 0 |

The jars are greased an inch deep at top inside, to prevent creeping. The cells are paraffined 1½in. at top, using a small bore lead tube as an inverted siphon to let out the air from the inside when dipping the cell mouth downwards in the melted paraffin. The zincs are battledoor slated, 7in. long, the blades being 4¼ × 2⅜ and ¼in. thick, thinned off to the edges, and weigh one pound each. A hook soldered on the shank hangs them on the edge of the jar. Three inches of the blade are amalgamated, the remainder and the shanks coated with sealing-wax varnish, as also are all the wires, to keep them from the action of the inevitable ammonia fumes.

The connectors I use are those figured at p. 340, Vol. XXIX., with the improvements as at p. 367, Vol. XXXVII., which are most convenient in use. The sal-ammoniac used is half a pound to each cell, and one pound dissolved in hot water added in equal quantities to each porous cell, in order to start the battery quickly, and the jars are filled so as to cover the amalgamated portion of the zincs.

This makes a useful, cheap, and powerful battery, easily examined, cleaned, and repaired, and one which I prefer to the well-known glass jars.

## A NEW INEXPLOSIBLE BOILER.

[24110.]—A BOILER of a new system, which received the name of Générateur Tricyclique Inexplosible, has been invented, which differs from all those hitherto produced. The metallic surface submitted to the action of the fire does not touch the water; in no condition can the boiler get red hot; it is enveloped all over by the same temperature, hence an immense vaporisation. Steam can be produced to the very last drop of water without the least danger. The spheroidal state, the decomposition into gas of the water, the elicitation of electricity in the metal, are thus avoided; the tremendous loss of heat now existing is diminished to such a degree, that with half the usual quantity of fuel a power more than fifteen times greater is obtained, and the steam-pressure can rise at will to 10, 15, 20, 30 atmospheres, and more, without fear of explosion. It appears that with some modifications the principle can be applied to existing boilers, but with less advantage.

## INTERCHANGEABLE MANDRELS.

[24111.]—I MUST apologise to "E. J. S." if I have mis-read his letter. I am glad to see that he does *not* advocate a long cylinder-fit as a substitute for the Edmunds' wide mandrel face with a view to prevent angular variation. But in this case, the questions raised by "E. J. S." are merely of theoretical interest, and I am not the man to assist in discussing them.

The general propositions set out in the first part of "E. J. S.'s" letter I fully admit, and I have already said that as we extend our bearing surfaces so we diminish pressure and lessen abrasion. If the cylinder base were, for the sake of argument, made by "E. J. S." a foot long, this axiom would still hold good. But "E. J. S." seems to forget that elongation of the cylinder base involves also the elements of time and distance travelled, as well as the division of the pressure over a larger surface, and the result is, that his argument is a fallacy whether he extends the cylinder base to a foot, or only, as he proposes, to an inch. The distance travelled and time taken up in screwing surfaces an inch long over each other are new elements in the problem, and have not been taken into account by "E. J. S." If, also, we put a cylinder base of one inch in length on our mandrel, we have an impracticable construction, and, as "E. J. S." expressly disclaims advocating it, what is the use of my attempting to discuss such a construction of mandrel head?

The question whether "two conical surfaces offer less difficulty in the attainment of truth than four surfaces at right angles to each other?" is interesting and important, and goes to the root of principles which need to be understood by all practical fitters. In my judgment, "E. J. S." is wrong in saying that this is so. If conical surfaces can be ground in together, it would be true; but in the "multiple fittings," which are required for mandrel heads, Dr. Edmunds is *perfectly* correct in saying that the two coned surfaces are less easy to make and less sure in their action than the four rectangular surfaces which he advocates. It seems to me that "E. J. S." has not fully studied the valuable papers which have been written by Dr. Edmunds on these points. I confess that I have perused Dr. Edmunds' papers in the *Journal* of the Amateur Mechanical Society (No. 25) and in the English Mechanic, with much help to a clearer understanding of the principles of our transfer chucks and interchangeable fittings.

The analogy which "E. J. S." draws between the interchangeable drills which I have for many years made does not hold. These drills have a long cone of great acuteness, and offering a very large contact-surface in proportion to their cutting edges. With a face-plate on a lathe mandrel these proportions are more than reversed, and, therefore, the same principle of fitting would not apply. Generalisings of this kind are often very misleading. As a practical man, I think that the coned mandrel-head will never compete with the screw-nose, and I believe that the Edmunds model mandrel-head, with its wide face for eliminating angular variation, and its cylinder-base for excluding eccentric variation, is a vast improvement upon the best mandrel-heads hitherto constructed. If this be so, we are only interested in points of detail, and one of these points which I am still debating is whether the nose-thread should have eight or ten turns per inch? Considering the large use of wood chucks, there is much to be said for adopting a thread of eight turns per inch, and then reducing the bore of the mandrel. From a private note which Dr. Edmunds sent when he lent me his model, I believe that he thinks this also. Will our contributors help us by giving their attention to this point?

In cutting V screw-threads with a milling-cutter, the correct practice is simply this. Use the milling-cutter for removing quickly the abundance of material, not for finishing; the point-tool for bringing up accurate sides, and the V lap-wheel for putting on the polish and the dead accuracy—no more—and that must be most carefully and delicately done; too much grinding here is like any other similar process; the abrading material cuts away where you don't want it, by collecting in heavier masses at one place than another. There is, however, no necessity to prolong a discussion upon the merits of a revolving lap, for either finishing a hardened lathe-mandrel, its cylinder base, shoulder face, or V-thread-nose of 50° angle; it has been done, and is regularly done, with an accuracy that none can dispute. And here, in my shop, may be seen an 8in. centre lathe which has been in use for years, having a V-thread screw-nose of $1\frac{6}{16}$in. diam; $7\frac{1}{2}$ turns per inch of 50° angle, and a shoulder-face of $2\frac{1}{8}$in. diameter which was so finished. The screw-thread is not hard, but about spring temper—a hardness obtained in the process of hardening that portion which runs in its hard steel collar, and the chucks are so good a fit to-day that a very small portion of dust will render them difficult to screw on.

Mr. Wenham's letters seem personal and offensive. As a sample of "dodging about," I advise our readers to study Mr. Wenham's last letter by the side of what has gone before. In every practical point which is in question, I venture to say that Mr. Wenham is also wrong. As a practical man, who worked at the bench and at the screw-cutting lathe for many years, I was obliged to differ from him. He then, after a rigmarole about hardening mandrels—which is misleading in every particular—turns round and suggests that, because my lathe mandrel-noses are soft, my tools are bad. Mr. Wenham either knows nothing about lathe mandrels, or he has said what he knows not to be true. When brought to book by me he simply "runs away," and writes about other matters. As I have already said, every reader who has a fine ornamental lathe, made either by myself, or by Holtzapffel, or Evans, will find that the nose is soft; yet Mr. Wenham neither retracts nor apologises.

Mr. Wenham's rigmarole, about softening the nose with a red-hot poker, can only amuse practical men. We never soften the noses at all, because we never harden them. We have methods by which we harden absolutely our mandrels on their running parts without hardening either the nose or the pulley portion. When Mr. Wenham is asked to give the addresses of "the best lathe-makers who now turn down their hard steel mandrels by a diamond splinter," he makes a paltry excuse about not wishing to advertise his friends by mentioning their names.

The specially-constructed steel I mentioned, was, I believe, originally made for Sir Joseph Whitworth and Company, expressly for tap-making. It is now to be had as a regular article in commercial use. I have used it for making my mandrel-taps for several years with the utmost satisfaction, and will send "Bow" a sample if he gives me his address.

Griffin Works, Norwich. **Edward Hines.**

## INTERCHANGEABLE MANDRELS.

[241 2]—Letter 24077 contains a question as to what are the requirements for making chucks interchangeable, and I am able to give the correct answer, which I do in this wise—viz.:—

1. As to "a cone-fitting [query—what is the proper angle?] to act as a guide to the chuck," I answer, Have nothing whatever to do with a cone-fitting at all.

2. "A shoulder to prevent the chuck jamming on the cone." Have a shoulder by all means. A true one, of moderate width. If you are in the habit of making chucks out of plank-wood, a broader shoulder is desirable than is required if you use metal chucks. In the latter case $\frac{3}{16}$in. is sufficient for a non-geared 5in. lathe with $\frac{5}{8}$in. nose, and one $\frac{1}{4}$in. is ample for a geared lathe of the same height of centre, with 1in. nose.

As to the "screw (not necessarily good fitting) to hold the chuck to the shoulder." Answer, I am not in favour of tight fits for the screws, and they may be very slack fits indeed, and yet accomplish all that is desired of them, subject to one only condition, and that is that they are good screws.

If you have a good screw-nose to your mandrel—and I fear that not many are to be found in a thousand to deserve the title—you may go on your way rejoicing, and consider yourself perfectly independent of all other centralising arrangements. If your screw is not well cut, no cylinder-fits or cone-fits, or any of those "jims" will be of the slightest avail towards the accuracy at which folk are now aiming. I never yet saw one so bad that it was not quite within the limits of correction by a few judicious touches in a screwing-lathe. It cannot be done otherwise.

Now I wish to say, once for all, that I do not intend to be led into any discussion: that has been done all ready to my hand, and I am not going to bother myself going through all that has been written. What I say I do not offer as an opinion, but as what I know from every-day practice, and what I know that I know. **J. K. P.**

---

[24113.]—We have to thank "E. J. S." for some ably-reasoned letters on the question of coned mandrel heads *versus* the screw-nose and mandrel-face, and for an interesting critique upon the model mandrel head which I have suggested. The question of coned mandrel heads is one of great workshop importance, and I shall follow carefully the discussion which will probably ensue among practical men.

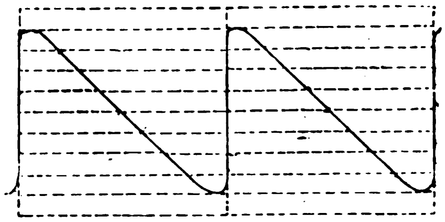
In case of sudden stoppage of the lathe, it seems to me that the cone and bayonet-catch will be unable to hold the chuck on safely. In one case, where such a coned mandrel-head was in use, I have heard that an accident happened, and that a flying face-plate injured a man severely. The fact that none of our great engineers have adopted so simple and obvious a principle in the construction of their foot-lathes is also heavily in favour of the practical superiority of the screw-nose and face-fitting.

I think that the one-cone fitting, though so simple in theory, is more difficult to make so as to fit solid from end to end than the two rectangular surfaces. As I have shown in a former letter, these multiple fittings cannot be perfected by grinding in.

The dead centre turning must always be more certainly accurate than turning on the live mandrel and one dead centre. The live mandrel must be truly concentric and quite in line with the poppet centre, and this is difficult to insure. In ordinary metal cylinder-turning, the live centre is not rigidly attached to the work, and acts only as a turnspit for work which adjusts itself by a sort of Hooke's joint to its own axis between the live and dead centre. Here the live centre needs only to be ground up true "in air" on its own mandrel, and its being perfectly in line is not necessary. This is next door to turning between dead centres. Turning in air also gives great accuracy.

It occurs to me that "E. J. S." has in some points allowed his algebraical forms of thought to carry him on to conclusions which may be fallacious by reason of the fact that his premises are more rigidly defined than his conditions can be. In one point (Fig. 5, p. 83) I would ask "E. J. S." to consider whether the line B.A. should not be reckoned each way alternately instead of only one way? I think that in every case the hold upon the chuck will be from the bite of the south side of the screw-thread to that point of the periphery of the face-zone, which is 180° therefrom in longitude. The south side of the screw-thread at C will only bite when the resistance at B acts. When the resistance at D acts, then the bite of the screw-thread will be on the other side.

This would make a vast difference in the comparison, though practically the solid bite which will be got in all cases upon my mandrel surpasses anything that can be got on the coned head. But I shall follow the remarks of practical experts with great interest. Another question as to thread-form for lathe-noses was raised by me ("E. M." No. 892, April 28, 1882), but hitherto has passed without discussion. In that letter (19973) I gave the following drawing:—



This thread was used by Sir William Armstrong for the breach pieces of his rifled cannon. It has the biting side normal to the axis of the cylinder, and the other side at 45°. By sharpening the angle so as to allow for truncation, this thread may be cut in the square, and therefore as deep as the length of its base. It is the strongest of all threads; it incurs no wedging, and the least possible abrasion.

If in this discussion we mix up the coned mandrel-head with one upon a different principle we shall all be at sea. The complete discussion of coned mandrel-heads and fittings is very practical and interesting. But we might first settle the remaining details of the modal form of the present screw-nose mandrel-head. I agree with "Vulcan," that "if the threaded nose is to be retained, there is little room for improvement" upon the model now before us. The only points that I see open for further consideration are the thread-rate, the taper of the centre-cone, and the outline of the shoulder. If the screw-thread have eight turns per inch instead of ten we get a thread less liable to jam the metal chucks on, and better for the wooden chucks so largely used in all delicate work. In this case the bore would have to be reduced from ·4in. to $\frac{9}{16}$in., so as to leave more substance in the nose for the deeper thread. "E. J. S." seems to take about the same taper as I have done for coning out the nose, but on this there has not been adequate discussion. What taper is used for the Morse drills and for the American chucks? For the model mandrel-head we require a taper which will hold the centre firmly without being so acute as to endanger the spreading out of the mandrel-nose under any reasonable pressure that can be given between centres. In my model the nose is turned out at 5° from the lathe-axis, and so as to leave the base of the hollow cone ·5in. in diameter. If the mandrel-bore is reduced to $\frac{9}{16}$in. the cone would have to be reduced to a base of ·4in. in order to leave proportionate substance in the screw-nose. As to the shoulder of the mandrel, the question is whether that might not be squared down further, so as to keep its outside diameter to 2in. The eccentric plate for the ellipse chuck has to be considered.

At page 124, "T. U. L." gives us a charming and perfectly-proportioned sketch for a combination of the screw-nose with double-coned centring surface. Theoretically, this is perfect, and it is most artistic. But, in practice, there would be so much difficulty in locating the four coned surfaces in their axial distance, that I fear this construction must be shut out from a design for multiple fittings where final grinding-in is not admissable.

**James Edmunds.**

## LATHE MATTERS.

[24114.]—I must reply to "Bow" in some sort, as he has such an astonishing memory for old utterances of mine, some of which I may now regret, and many of which I have forgotten long ago. The letter to which he refers, in Vol. XVI., is, I see, from our old friend, the late "H. B," and that it commences by saying that he is not "J. K. P.," and does not pretend to possess practical information approaching his on lathe-making, as his own experience dated back only about half-a-century. Well, I am not quite so old as that, yet it is forty years this month since I was head of the workshop at King's College, and it is not much less than thirty-two years since I first wrote "Civil Engineer" after my name. So I am now getting towards that period of existence at which I dare say I may be thought a bit of an old fool, and only fit to poke fun at, just as, when I was younger, I fear I was too much inclined to think of "H. B." I regret it now extremely.

Hollow mandrels, such as that letter describes, used to be in vogue some years ago, and something like them is, I am told, made in America now. Mr. Clements had several, that descended to his nephew Mr. Wilkinson, and I have now one that was copied from them. I would not make another, and though I like that fitting for drill-spindles used in slide-rest, I do not hold in the least with the need of having any such fitting with cylinders or cones for lathe chucks, provided always—and this is absolutely essential—that the screw-nose is well cut. It must be done in a screwing-lathe, as it is impossible to do it by hand. I have two pairs of mandrels—one pair of 1in. and the other of ⅞in. diameter, each with Whitworth's ordinary bolt-thread, which is the strongest thread that can be found, meaning by "strongest," that which will endure the most work with the least deterioration; and those four noses will, two and two, bear the same test as those recently made and exhibited by Mr. Evans. I showed that gentleman two of them screwed into one chuck a few weeks since; but as I have taken the chuck for another purpose, I am not able now to exhibit. The other two are likewise so accurate that I make and finish the chucks intended for one of them on the other one, as the latter happens to stand in a more convenient position in my shop.

Now, going back to Vol. X. p. 476, the expression "capital result," referring to the facility of doing the job with a circular cutter, as compared with the attempt, or, rather, the failure, to accomplish it with a single-pointed tool in a weak lathe, and not to the resulting thread, which is not of a very good shape. As to cutting screws in hard materials, as a matter of practice, I must leave Mr. Wenham to defend himself, as he plainly understands what it is that he is writing about; also writes in a language understood by the general public, and may as well be left alone. There are one or two things that I may say: such as, If you use a circular saw-cutter, or grinder, to cut a groove (I was very near writing "zone," only that I tremble lest a zone should turn out after all to be a piece of a plane, and not of a cylindrical surface, and I therefore be corrected)—well, say a groove, in a cylinder, with the slide-rest stationary, and your cutter running in a plane perpendicular to the axis of the cylinder, you do get a groove which is the counterpart of the cutter used, and in this one instance no attention need be paid to height of centre. The only other position in which you obtain a counterpart of the cutter is when the cylinder is stationary, and the cutter placed and moved horizontally. You then, by repeating the groove at intervals, get a thing like a fluted column. When the cylinder revolves, and the cutter is drawn along simultaneously, as in screw-cutting, the nearest approach to a counterpart is gained by placing the cutter at the same angle as that which the desired thread has at its mean depths, but as that angle is not the same as the angle of the top of the thread, nor yet as that at the bottom, the result is that the groove, when completed in outline, is not like the cutter that produced it. In this case the strictest attention to height of centres is imperative, or the thread will be lopsided, in addition to its other defect. A cutter made for a screw of any particular number of threads will not do for any other number.

As to poppet cylinders, and tightening the same, I very seldom take the trouble to tighten mine, which happens to fit, and has the steady-pin vertically under the top set-screw. I think for small lathes the screw on top is handiest, but in big ones, where the work is often swung into the lathe by a crane, it would run great risk if so placed. I once saw one which had three sliding keys inserted between the cylinder and the barrel, and forced up by what on a steam pipe would be called a "union," which was screwed on to the projecting nose of the barrel.

"Mild steel," "homogeneous iron," or "Bessemer steel" is now sold by Pfeil and Co. in Broad-street, Bloomsbury, and in St. John-street, Clerkenwell. I believe it to be very various in quality from different makers. I have some that came from Vickers's Don Steelworks, Sheffield, some years ago, that turns like annealed cast steel, so hard is it. Some from Pfeil's is as soft as charcoal-iron. I have had mild-centred steel from Stubbs's and from Vickers's. I am told that it is mild steel with an extra treatment in the carbonising furnace, or is it carburetting? I know not.

The fitting referred to in last paragraph but two of letter 24074, is very like one that I have used for the wrought-iron lever handles of a planing-machine screwed into a central boss, and for that purpose is, I think, better than any. I think it would be a very bad one for chucks, and supremely difficult to fit.

J. K. P.

## LATHE MATTERS.

[24115.]—In reply to "Bow" (24073), I have to state that as Bessemer steel has now superseded iron for the spindle work of all small machines, it is kept in stock at most of the large ironyards, such as Moser's in the Borough, but they will not cut a piece off a bar for you. There is also a fine mild quality, suitable for lathe mandrels, known as Atlas steel, as made at the Atlas Works, Sheffield. The special steel with the "mild core," mentioned by Mr. Hines, cannot be cast steel, and therefore, as it is not homogeneous, I would rather not use it. I know of no process by which an ingot of steel can be cast with a "mild" centre, and poor steel carbonised up to get it to harden is fit for nothing as a tap, or any cutting tool. I can recollect the time when a bar of blistered steel (that is, all covered with bosses just as it left the cementing trough) drawn down with hammers from a welding heat, was thought good enough for some cutting tools; these bars, of course, had an iron or soft centre.

As to the milled and afterwards lapped screw-thread, the argument seems to be drifting into the ways of doing it, instead of the question of utility and practicability. What is the use of making a milling cutter "of the true curve and shape," to fit the form of the thread, or that will drop through somehow? This cutter, with a distorted periphery, should have every tooth or cutting edge relieved backwards, in order to be an efficient workshop tool, and this would have to be done by hand-filing—a most careful piece of work. Any workman that would waste a week of his employer's time in attempting to make an accurate screw by such means, would forfeit his character for skill, and perhaps his place too. A lopsided thread for a mandrel-nose is not desirable, as a chuck or piece of work has sometimes to be tried on the reverse way, and for this reason alone the screw-thread should be equal-sided.

F. H. Wenham.

## STANDARD MANDRELS.

[24116.]—My last note (24098), page 129, requires the following addition and correction: Paragraph 5, line 2, "shaped as" should be "shaped similarly to one." A cutter shaped strictly "as," would produce a true axial section, as is usual in screws. Last word of last but one paragraph is a misprint of "both" for "bolts." The V-point tool referred to as normal in paragraph 2, is, of course, the form of tool in question.

I have resolved, the following being the main whys, to give my definite adhesion to the Edmunds mandrel. I am convinced—

1st. It is the simplest centring mandrel forthcoming, or likely to be so.

2nd. It has been proved efficient, and has met the approval of ornamental lathe makers.

3rd. A reliable male cone fitting cannot be made with so short overhang.

4th. There is nothing to jar loose and cause disaster.

5th. Existing mandrels may be utilised and adapted.

6th. For my special needs of frequent change, &c., I can easily "match-piece" to it my coned nose, with pin-key, sleeve and check action to prevent jarring loose, and the other improvements "too numerous to be catalogued," and that without increasing overhang.

7th. The expense for multiple fittings will be comparatively slight, as there is no broad departure from present workshop practice.

Any mandrels for lathes I may in future make or obtain, will be, as far as possible, the same as Mr. Evans has stated his intention to introduce.

I hardly think the "E.M." correspondence represents general opinion, and I am tolerably assured that introduction by makers is all that is needed to cause general adoption.

The minutiæ perhaps still need those developments that practice alone can lead to; but that, I think, is all.

Vulcan.

## DIAMOND TOOLS.

[24117.]—I use a diamond for trueing up emery wheels, or turning to definite forms for sharpening, milling and other cutting tools; but the diamond does not in this case act as a cutter, for it is in reality a blunt piece of stone without any sharp corners; its action is rather one of bruising up, and dislodging the particles of emery. As my own manipulation is now principally with small tools, for grinding these, instead of the dirty, sloppy, wet grindstone, I prefer a hard-grit dry stone always at hand, run in an old lathe. This soon gets smooth and clogged up with the abraded steel; to continue to use it in this state would cause the edges of the tools to get heated and softened, therefore the grindstone has to be frequently cleaned and trued up. I do not employ the diamond for this purpose, but set the T-rest of the old lathe rather high, and about an inch away from the stone revolving forwards. I then take up a piece of spring or busk steel, and hold it against the stone; this causes a horrible noise, but the steel chatters out a series of cross grooves in the edge of the stone, which cause it to grind the steel very rapidly without the risk of overheating, and I thus always have a grindstone running perfectly true.

The extraordinary durability of the diamond, or carbonado, is most apparent in the operation of facing, or, as it is termed, "cracking" a millstone—that is, covering its grinding face with fine furrows. The French burr stone is a most intractable substance, and is, in fact, equal to flint in hardness, and full of pores and cavities; when the surface had worn smooth and required to be redressed by the old means, a dozen or so of mill picks, ready sharpened and made of the hardest steel, were given to the workman, who armed his hand with a leather guard to prevent the flying particles from penetrating his skin, and who then dexterously chipped out the grooves, as if he were cutting a file, the fire from each blow appearing to sink into the stone. As soon as one pick got blunt, another was taken up, and the whole stock would be required to complete the job. Now one little piece of carbonado, set in an ingenious sliding or dividing frame, does all this work, without any deterioration or diminution in size, but in action is not that of a cutting tool: it furrows out the millstone by a percussive action.

"Z. Y. X." is no doubt familiar with all the uses of diamond for a cutting tool. He mentions 2s. 6d. or 3s. as having been the price of a piece of carbonado the size of a pea. That may have been the case at its first discovery, before its value was known; now such a piece would cost as many pounds as he has named in shillings. The material for making the slicer for a lapidary's mill is well-annealed charcoal iron, such as is used for the best tinplate before being tinned; but it is difficult to get this anywhere in London; and if the tinned iron is to be used, all the tin must be wiped off while hot, and the last trace of it removed with a piece of wet pumice or gritstone: otherwise the slicer will be spoiled by pieces of diamond sticking in the sides. As to an agate roller for charging the edge of the slicer, this is just the material most unsuited to the purpose, for the diamond would speedily pound and dig out a rut around the edge. The diamond powder imbedded in the edge of the slicer has very little action on hardened steel. It merely grazed the edge of my roller. I could have wedged this fast or used it sideways like the usual burnisher, but I did not, because it acted best as a roller. One of the worst applications of diamond powder is to use it for abrading malleable metal, wherein it fails to act. When I first began to use diamond turning tools, I lost some pieces from the imperfect mode in which they had been set. I therefore had to devise means of setting them securely, in order to stand rough usage. Several years ago I described my methods in the "E. M."; but as this subject is now again brought to the fore, I will do so again—in the next issue, if I can find leisure.

F. H. Wenham.

[24118.]—I propose in future to drop my title "Z. Y. X."

I wish all persons interested in diamond tools, and their use for stone or hardened steel, would send me all information they can, as I think (but do not promise) of writing a full description of the use and origin of the carbonado tool—not the use under continuing patent of the same material, but expired patent only.

Dr. Edmunds will perhaps exchange letters with me on the subject.

By the way, is it true that the Amateur Mechanical Society have decided against Dr. Edmunds in his Interchangeable Mandrel question? A question in which, 15 to 20 years ago, and since, and still at the present moment, I agree with him.

I agree with Mr. Wenham in his remarks, p. 126, under letter "Cutting Screw-Threads," where he says that when laps are used, &c., &c.; if he means (but, query, Does he not mean the contrary?) that there is a danger of the diamond (or emery) getting into the steel which is being turned. This is not chimerical, for I have, within the last week, heard of makers of arbors of watches coming to grief through using adamantine; the result being that the arbor became charged with the adamantine, and so the jewels were in a short time cut, and the watches returned as faulty.

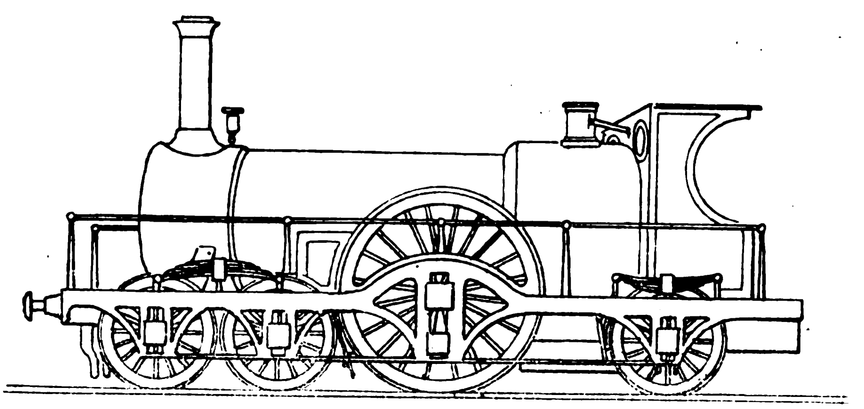
A. P. Bower.

35, Mecklenburgh-square, W.C.

## THE CASSEGRAIN—THE MUSICAL SCALE.

[24119.]—Writing in both cases very hurriedly, I seem to have made mistakes in both my letters. I should have referred to the Gregorian small mirror as receiving diverging instead of converging rays (though the principle to which my remark applied is the same in both cases); and, as pointed out by Mr. Hunt, I incorrectly described his table of ratios. As regards the latter subject, I trust to continue the correspondence next week; my time is too much occupied to do so at present.

A. S. L.



## ACCELERATION OF TRAINS, BRAKES, &c.

[24120.]—In answer to Mr. Lawrence (letter 24033), I send sketch of G.W.R. B. gauge 8ft. single, and will send sketch of G.W.R. B. gauge 6ft. 6in. coupled if desired. I will find out whether the N. gauge rails are laid from Bristol to Penzance.

Could Mr. Lawrence or some other correspondent kindly send sketch of M.S. and L.R. 7ft. 6in. single?

**G. A. T.**

## THE "ROCKET."

[24121.]—I should feel obliged if someone amongst your numerous railway readers should be able to reply to the following query. I think I may venture to assume that the question is of considerable historical interest to many.

What kind of valve-gear was fitted to the "Rocket" when she competed for the prize on the Manchester and Liverpool Railway in 1829?

Was it of the simple kind, with eccentrics independent of each other, but loose upon the axle, driven by "snugs," as was the case in many of the early locomotives, and which is still in use on the penny boats plying on the Thames; or, was it of the modified arrangement of gear which is illustrated and described by Pambour, in his work published in 1836, in which the two eccentrics, although loose on the axle, are permanently fixed together on discs, which are larger than the eccentric sheaves being fixed to the outer side of each, and concentric with the axle; each disc having an aperture near the circumference, the whole being movable transversely on the axle by a lever from the footplate, and can be thrown in or out of gear with either the right or left hand "driver" for forward or backward motion, these drivers being fixed permanently on the driving axle in the proper positions, and having projections which may enter either of the apertures in the discs above-mentioned.

Now, the first-mentioned simple gear does not admit of the motion being reversed until the engine is first stopped, and the valves shifted by hand previous to re-starting in the opposite direction. The second and modified arrangement does admit of the reversal of the slides without bringing the engine to rest.

A few words contained in an old book has suggested this query.

It should be observed that the gear now in the "Rocket," at South Kensington, is of the kind last described, but the transverse displacement of the eccentrics is effected by a pedal lever on the left of the foot-plate, which, by treading, would move the eccentrics into gear with the right-hand driver, but no means are apparent of moving them in the opposite direction.

It seems somewhat strange and unaccountable that so little is known, or has been published, respecting the interesting details of this most celebrated engine.

**Telegraphist.**

## OLD LOCOMOTIVES.

[24122.]—Your correspondent "Nun. Dor.," page 108, No. 55933, has referred to the fact that a locomotive was used on the Canterbury and Whitstable Railway. The engine in question was built by Messrs. Stephenson, in 1830, and ran at the opening of this early railway, 3rd May, 1830, being driven by Mr. E. Fletcher (afterwards of the North-Eastern Railway). It was named "Invicta," and was sent by the South-Eastern Company to the Stephenson Centenary, 9th June, 1881, upon which occasion I made a sketch of it. This old engine ran upon four wheels, of 4ft. diameter, coupled; the cylinders being placed diagonally outside the smoke-box.

As the "Invicta" was sent to Whitstable, and was at work for twenty-six days *before* the Act for making the Swannington line was passed, it is perfectly certain that the author of "The Midland Railway: its Rise and Progress," made a serious error in stating that the engine sent to Leicester in 1832 was the first locomotive that ever ran south of Manchester. As "Nun. Dor." remarks, historians too often record what they *believe* to be true, instead of being sure of their facts and dates; thus an error or incorrect statement is perpetuated, and handed down to future generations.

Leicester, 13th April. **Clement E. Stretton.**

[24123.]—In the English Mechanic of the 3rd inst., under the heading of "Old Locomotives," I see a correspondent refers to the Canterbury and Whitstable line. Allow me to inform you that this was opened for goods and passenger traffic on the 3rd May, 1830. It was worked by stationary engine from Canterbury through the tunnel to Tyler Hill, where the engine was fixed. There was another stationary engine farther on at Clowes Wood, from which the train ran down a declivity, drawing the rope out behind it to a level called Boyshole, the rope being left there ready for the engine to draw the train upon the return journey from Whitstable. On arriving at that place from Canterbury, the locomotive engine "Invicta," with the ramping horse on the side of it, took the train on to Whitstable, and brought the next train to this point, where the rope, as I have already stated, was previously left ready to take it on for Canterbury.

You can rely on the correctness of this statement, as I was at the opening, and have been in the office for the last 45 years.

Whitstable, April 7. **Edw. P. Read.**

## ENGINE AXLES.

[24124.]—I hope the great question of crank-axles breaking will not be passed over in silence by our railway readers.

Is iron or steel the best material for making such axles? What are the forces acting on these axles, and where is greater strength required?

**Inquirer.**

## BRAKE FAILURE.

[24125.]—I see on page 128 that a serious failure of the vacuum brake has happened at Kentish Town; but there has since been another, for on Good Friday morning the midnight express, with two engines and some 22 passengers, ran all the front part past Bedford and had to be pushed back. Could "Meteor" also give the cause of this?

**A Passenger.**

## NEW MIDLAND ENGINES.

[24126.]—It seems that since "Locomotive" wrote his letter, some alterations have been made in No. 1675, and on Thursday, 9th inst., she had yet another try to run the 10.35 from London. However, she made a poor show, losing 5½ minutes with this important Scotch express, on a nice day, with a moderate train of only 12 vehicles.

Is it true that these big engines have 100ft. less heating surface than the 800 class? If so, it accounts for all lost time. **One of the Passengers.**

## MINERAL-OIL LAMPS.

[24127.]—I have read with some surprise Mr. Hughes's remarks on the above question. He evidently advocates the use of non-conducting glass or earthenware (and consequently breakable) containers: my experience in these matters is the reverse. That there *are* metal containers, which cause an inflammable gas to be generated, I do not dispute; but I have found that glass containers possess the same defect to a great degree. I have a "Silber" which has "blown up" several times, and has continued to burn in the container until the air supply it contained was exhausted. This has an opal glass container, and the burner and adjacent glass gets so hot in a quarter of an hour that it is next to impossible to handle it or carry it about, and on taking it from one floor to another, one has to set it down on the stairs to rest one's fingers from the intense heat, for a second stage of transport. I have also found other glass container lamps to possess the same defect.

There is a lamp in the market at the present time called "Martin's Patent Duplex." It has a circular burner and a metal container. This lamp, from its ingenious and peculiar construction, obviates the defects of both bad metal and glass lamps. First of all, there is no space communication with the reservoir, neither through the wick-channel nor through the base of the burner, which unfortunately exists in too many, in the shape of a small round hole about $\frac{3}{16}$in. diameter (quite sufficient to allow of an explosive gas being ignited). The wick is in two halves, and is fed up the burner by two pinions instead of one, and these being independent of each other, the flame can be adjusted to the greatest nicety, that abominable defect called "steepling" being thereby reduced to a minimum; but the most beautifully useful and ingenious part, perhaps, in the whole lamp, is the "radiator," or heat dissipator, which consists of a flat perforated metal disc about 4in. diameter, which is slipped on to the burner just below the flame. The office of this radiator is to get rid of the heat generated in the burner, which it most effectually does, both by convection and radiation, and it performs this office so completely that on placing one's hand on the burner itself, one can only just distinguish a slight pleasant warmth, whilst the reservoir is at the same temperature as that of the room, and this after burning 15 hours. My lamp before me now, by which I am writing this, has its reservoir as cool as if the lamp were not alight. Therefore, I think Mr. Hughes must admit that metal containers are not only good, but can be immeasurably superior to the glass or earthenware ones now in use, even if Martin's burners were applied to them; for, in the case of the metal container, no accident *can* happen from fracture or the generation of inflammable gas. I may mention that, light for light, I have found the Martin's lamp more economical than any other I have used. It further has a very ingenious and cleanly appliance for trimming the wick, whereby the use of scissors is done away with.

**P. Ward.**

[24128.]—J. Hughes is informed that some time ago I had the temperature of mineral oil in copper reservoirs tested every hour during ten hours' burning at full combustion. After the first hour the temperature was 68° Fahr.; the highest reached was 69·2° Fahr.

As he claims for himself great practical experience, he ought to know that overheating is caused by the metal wick-tube being in the oil, but that the slight warmth conveyed by the wick alone is not a cause of mischief.

The wick-tube at the flame end is at great heat, and only less hot at the other end, which, therefore, should be as short as possible, and not touching the oil. **J. D. Shakespear.**

## CURIOUS OPTICAL EFFECT.

[24129.]—The appearance observed by Mr. Culley (letter 24087) formed the subject of a question in the papers for the Mathematical Tripos at Cambridge last May. The several rings are due, not to interference, but to the number of internal reflections necessary for the rays to meet the eye. The distances from the eye, placed close to the end of the barrel, are $\frac{1}{3}$, $\frac{1}{5}$, $\frac{1}{7}$, $\frac{1}{9}$, &c., of the length of the barrel.

**Pi.**

## CHOLERA BACILLUS.

[24130.]—My attention has been drawn to the remarks of Mr. Nelson, in your issue of the 20th ult., upon my claim for the discovery of the cholera bacillus 35 years ago by two Englishmen. I was prepared to find that my views would be questioned; but certainly not upon the grounds of the two objections laid down by Mr. Nelson. Staining with aniline dyes most likely was not in use at that date; but there were other ways of preparing objects than by staining, and as this has supplanted other methods, so it will, in all probability, itself in time be superseded.

With regard to Mr. Nelson's second proposition, is Mr. Nelson prepared to argue that because Malpighi was not in possession of the improved instruments of the present day, and staining reagents were not in use, it is, therefore, doubtful if he discovered the Malpighian Corpuscles in the kidney, or that the discoveries of Leeuwenhoek, Swammerdam, and others, can be impeached because their instruments were comparatively defective? It is well known that many of the most important discoveries have been made with inferior instruments. Mr. Nelson is fortunate in living in an age when the microscope and objectives have each been brought to their present perfection, and when objects can be demonstrated more clearly by the method of staining; but surely he does not therefore conclude that nothing so minute as the "Comma Bacillus" cannot have been previously seen and described as far back as 1849. I would beg to refer him to the literature of that period to dispel his illusion, should he still remain in doubt.

A friend who has seen Mr. Nelson's remarks in your journal has written to me to say that "with a Nachet's" No. 5 objective of about that date, he has seen and shown to another party the acknowledged "comma bacillus" both in the dry and wet state, *unstained*, the magnification about 450″. As a matter of fact the lens used by Dr. Brittan was a 1-12th Andrew Ross; that used by Dr. Swayne was a 1-8th Powell and Lealand, both of sufficient power to well show the curved bacillus, for I possess a 1-6th objective by Andrew Ross, and can with it, and without the aid of an achromatic condenser, distinguish the "comma bacilli" in an impure gelatine cultivation, *unstained and mounted wet*. The descriptions furnished in the recent original and valuable investigations by Dr. Koch, so closely correspond with the statements by Drs. Brittan and Swayne, and the general evidence is so strong, that it will require far more valid arguments than Mr. Nelson offers, to disprove the claim that these gentlemen were the original discoverers of the curved bacillus, which by its supposed relation to cholera, so seriously engages attention at the present time.

**Francis Fowke.**

## MICROSCOPE CONSTRUCTION.

[24131.]—I may, perhaps, be permitted to inform "Nemo" (24084) that many letters and papers have appeared in the English Mechanic on microscope construction. The plan which I should advocate for those who wish to construct anything of the kind, is to look over the back volumes, and decide upon the kind and class of article they wish to make, and should a difficulty arise, to put a definite question. I can say, without fear of contradiction, that anyone who is a decent mechanic, and who has access to the back volumes of the "E.M.," can make a microscope without further instructions. There are plenty of back volumes to be purchased cheaply, and there are figures, without end, of microscopes, also pattern making, lacquering, &c. With a little ingenuity it is perfectly possible to make one almost entirely in the lathe, so that vice work should be reduced to a minimum.

I am quite sure there are very many readers of the "E. M." (amateur mechanics) who can execute the brasswork of a microscope which will give results equal to one of the most expensive kind which can be purchased from an optician; glass grinding is, of course, out of the question. No sane amateur would think of doing this. No one should attempt such work unless he has seen and examined at least one instrument. A mere copyist will experience more difficulty than a workman who can modify the design to suit his own capacity, and the tools which he happens to possess. The glasswork must be purchased; but a really intelligent man who can use his lathe ought to be able to make for 20s. that for which he would pay an optician £10.

**Os.**

## MICROSCOPICAL.

[24132 ]—With regard to "R. D. R.'s" letter (p. 110), I should like to say that many professional readers would be delighted to hear of a cheap Stephenson's erecting binocular with *very short* tubes (not having too great a slant), and fitted with two powers, one like Zeiss's *variable* low objective, and the other, say, about ⅔in., so as to give a range of powers from 20 to 60. If this *ideal* microscope could further have wood support applied to stage (for hand rests), and be supplied at £5 to £6, I may safely predict it would have an enormous sale, and would *do all* that any binocular can for natural history, dissection, &c. With such an instrument, and *one other* for high powers, the scientific worker would be completely armed. With regard to the high power instrument, a very short monocular one is best. The fine adjustment must be *perfection*, must be supplied with a good achromatic condenser of low angle (say 100°—80°); draw tube (so as to suit all makes of o.g.), and three powers one-third of 60°, one-sixth of 90°—100°, and 1-16th of N.A. 1·33 (oil or what not); two or three eyepieces, powers from 100 up to 1,000 or so. Such an instrument can be had for about £20. I think it is as gross a mistake to expect the one stand to do all manner of work, as to exact every, no matter how different, requirement from the one object-glass. (The binocular is not of the slightest advantage for high powers. The rest it affords the eye can as suitably be obtained by other plans without its expense and cumbrousness.)

For goniometric, polarisation, and spectroscopic observations a totally distinct instrument, or rather set of instruments, should be used.

I am sure my remarks will be borne out by the experience of practical men. If makers would give more of their attention to perfecting a *set* of instruments to suit the varying requirements of different workers at as low prices as possible, I think a decided improvement would set in. By all means, let us have object-glasses *perfect*, and, as a necessary corollary, *perfect* fine adjustment, and *perfect* illumination devices; but why hamper us, in our seach after these, with the fruitless attempt to make one instrument suit all needs? Producing huge monstrosities—monstrous for price as well. Because we require magnifications, must every magnification tool attempt the function of every other magnification tool whatsoever? I do not mean to contend that *all* attempts at combination are impossible, but only that such combination *in the main* limit, and do not extend, the advantages of the instruments so combined. A statement I think most will agree to be not only true, but trite.

Let the motto of the artist be that of our artist mother Nature, "Specialisation of function, with (where possible) simplification of organ—simplification with specialisation."

I should be very glad if anyone having had experience of them, can give me an opinion as to Seibert's water immersions: they are very cheap. A $\frac{1}{16}$ I have resolves Amphipleura pellucida, with mirror alone at small inclination only, and with central light from condenser. Are the higher powers good?

Dublin, April 5th. **Francis D'Agen.**

## LAMINATED ARMATURES.

[24133 ]—I was rather surprised to see Mr. Chaster's letter, 24041, after Mr. Bottone's paper, where he described his experiments with both the solid and laminated armature, which clearly shows the laminated armature to be far superior in every way to the solid, both in dynamos and motors.

That Mr. Chaster should recommend to amateur electricians the old solid form, in preference to the new laminated or discs, which I consider simpler to construct, it requiring but little turning.

Respecting the insulation of the wire being cut through by the discs setting up a small counter rotary motion, and exposing sharp edges to the wire, I suggest that the discs be mounted on a square spindle turned up at the ends for the bearings and tightening screw.

West Dulwich. **W. Habgood.**

## A FEW MORE WORDS ON THE NEW TIME.

[24134.]—Various circumstances have prevented me from replying to "Nun. Dor.'s" letter (23961, p. 57) criticising my remarks on the "New Time" (letter 23949, p. 36); but now that an opportunity occurs, I may say that though your correspondent states that he "cannot agree" with me, his letter really confirms the opinion I expressed respecting the general adoption of the new-time nomenclature.

It may interest "Nun. Dor." to know that I had Sir E. Beckett's objections in my mind at the time I penned the words, "it is a matter of considerable uncertainty *at present* (I italicise these words as they appear to have escaped "Nun. Dor.'s" notice) whether the 'new time' will ever become part and parcel of our everyday life." It may or may not be as "Nun. Dor." affirms "a long fly from here to 'ever'"; he must remember that I did not use the word *never*; and when we take into consideration the divided state of opinion respecting the advantages of the "new time," and that Sir E. Beckett, as president of the Horological Institute, may be considered to have some influence amongst those most affected by the proposed change, I am inclined to think that your readers will agree with me that "at present" at least it *is* uncertain whether it will ultimately become the civil mode of dividing the day.

"Who are the people," asks "Nun. Dor.," that are "confused" by railway time-tables as now arranged? To this query I can only reply by saying that several persons who are generally included in the phrase "the masses," have told me that when they have had occasion to refer to the time-tables to see when they would arrive in London from Scotland or Ireland, as the case might have been, the frequent "a.m.'s" and "p.m.'s" have not a little bewildered them; and, moreover, one of the British delegates at the Washington Conference, who is a distinguished mathematician and astronomer, admitted before a meeting of one of the leading London scientific societies, that on one occasion he was misled through mistaking "a.m." for "p.m." in a railway time-table; a mistake into which it is needless for me to say he could not have fallen had the "new-time" nomenclature been used.

However "priggish" it may seem to Sir E. Beckett—with whose opinions on many subjects but this I agree—and however "vague" it may appear to "Nun. Dor.," I must still adhere to the "notion" that the "new time" nomenclature is of a much more sensible and scientific character than the present; and I shall be obliged if he will show me in what way it is not, apart from such mechanical considerations as the striking of the hours and division of the dial, which are difficulties (?) we may leave to practical horologists to surmount.

The division of the day into two parts, "ante meridian" and "post meridian," was a quite natural and reasonable division when the flight of time was marked by the shadow of the gnomon of the sun-dial; but now that species of time-measurer is no longer employed excepting for ornamental purposes, I contend that such a division of the day and the retention of what, for want of a better phrase, I may call the sundial nomenclature upon the dials of modern timepieces, is one of those things that might be altered with advantage.

Forest-gate, E., April 6. **B. J. Hopkins.**

## MUSICAL SCALE.

[24135.]—Mr. Hardie (letter 24020) will have great difficulty in proving that the musical scale in melody is different from that used in harmony, although he states this as a fact on page 522, No. 1038. Melodies are almost invariably harmonised, either in full or by accompaniment, and such a difference would lead to confusion worse confounded. "A. S. L," on page 499, No. 1037, says that "W. H.'s" letter, page 477, will be a great help to him in the matter he has in hand, evidently considering the monochord proportions there given to be the correct ones, because they appear in the English Mechanic; but under the heading "Letters to the Editor," we are told that the Editor does not hold himself responsible for the opinions of his correspondents, so we must weigh before accepting, and let the present letter be no exception. For this reason I think no doubtful matter should be allowed to pass without challenge, as some readers may get incorrect ideas if both sides of the argument are not presented for their consideration.

On page 81 of No. 1044, Mr. Hardie takes exception to the statement that musical ears demand simplicity of ratio between the notes of the scale, and says, "All that musical ears demand is only that the notes of the scale shall sound *in tune*." Will Mr. Hardie kindly say what property the notes are to possess that they may sound in tune, as he leaves us in the dark on that head, only saying that this property is not necessarily simplicity of ratio? What is the difference between the notes of a violin when stopped by a good performer, and consequently in tune, and when stopped out of tune by a beginner? One of simplicity of ratio unquestionably, for it can be clearly demonstrated that the ratios in the first case are far simpler than in the second. Those given in my letter on page 10, No. 1041, may certainly be called simple—although denied by Mr. Hardie—as the products of the numerators and denominators of the various fractions are the smallest compatible with the positions of the various notes in the scale—viz., between 1 and ½, and the most complex there is simplicity itself compared with some in Mr. Hardie's scale, especially after a little modulation. For instance, his A sharp would be 32768/59049, while mine would be 72/125, and his F double sharp 1048576/1594323.

We shall be safe in assuming that Mr. Hardie's ear will acknowledge the scale as in tune if given the proportions named by him on page 37, No. 1042, and also in his division of the monochord, page 477, No. 1036. Now, I will not pit my ear against his by saying that these proportions do not satisfy my requirements of being in tune, as it may be said my personal equation is unknown; but I will ask, is it not a fact established by the consensus of all the musical ears of pianoforte-tuners and others, that the major-third of the equal temperament tuning is considerably too sharp, and that if the fifths are tuned too perfect these major-thirds will be unbearably sharp? Now his measure for E in the key of C is 64/81, and as the comparative values of decimal fractions is more easily seen, we will convert it into $\cdot\overline{790123456}$. The correct measure is 4/5 or ·8, and the equal temperament measure is $\sqrt[3]{\frac{1}{2}}$, or ·7937005, because three major-thirds are made to equal an octave. Compare these figures, and it will be seen that although the equal temperament major third is as sharp as the ear will allow (and sharper than some can stand), yet Mr. Hardie makes his considerably sharper, and wishes us to accept it as a note in the natural scale. The ear clearly says it is not so, and what else shall we set up as judge? All his major thirds have the same error, and as the minor sixth is an inversion of the major third, all these have the same error inverted —viz., they are too flat by a like amount, his measure being ·6328125, the correct ·625, and the equal temperament ·6299605. His major sixths are too large and minor thirds too small by a greater amount; also his major seventh is too large and his minor second too small; my proof of all which would be the same as above, but omitted here for brevity. As we are arguing simply for the purpose of arriving at truth, I ask Mr. Hardie to examine this, and if he cannot advance a reasonable objection, to admit the point in the interest of readers who are not in a position to test the matter, and yet might wish to make use of the measures.

The only correct intervals in his scale, with the exception of the acute major second, are the fourth and fifth; but why he should say an ear that accepts any other proportions than ¾ and ⅔ for these must be defective, I am at a loss to understand, as no one has set any other values on them.

True, you cannot modulate indefinitely by perfect fourths or fifths; but this is what Mr. Hardie seeks to do, with the result of getting A flat below G sharp, and like errors. It is not necessarily fatal to a musical scale that it needs more than one note changed to fit it for modulation into the next remove—indeed, the ear asks for a change of three notes in the composite scale, which includes the major and all the minor scales in a key, and which I give on page 10, No. 1041. This cannot be considered as built on the harmonic theory; but on the principle of simplicity of ratio, for the harmonic theory fails on arriving at the seventh partial, the ear objecting to any division by seven or any higher prime; beside the dissonances are evolved by modulation.

It may not be possible fully to explain why the ear accepts as in tune notes that bear a simple proportion to each other; but it is clear that the presence or absence of this quality determines the matter. The investigations of scientists have left no doubt that the effect which we recognise as difference of colour is due to differences in the vibrations of the luminiferous ether, and simplicity of ratio here also has been found to produce harmonious results.

I believe these differences of opinion as to the measures of the notes are hindering practical men from attempting to solve the problem of practical application, or putting them on the wrong track.

**S. E. Hunt.**

## REPLIES TO QUERIES.

◆

**** In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[54825.]—**Salt, &c.**—Perhaps "Marienberg" will tell us by what "agencies" cereals do reproduce themselves and multiply, if not by natural ones? By whom was man taught the unnatural cultivation of cereals? Is the cultivation of, say, rose trees, fruit trees, vine, &c., also non-natural, &c., &c.? In fact, is there anything which man has had a hand in natural? How do the savages in all parts of the world, who live entirely on "natural products" of their countries, exist if nature is not enough for them? If the primitive ancestors of our race were civilised, where are the records of their civilisation? Do the geological strata contain the slightest traces of them? Surely if primitive man cultivated "cereals," we should find a "fossilised ploughshare" somewhere.—F. W. H.

[56015.]—**Steam-Hammer Valve.**—Replying to "Essar" (56015), allow me to say that twelve months ago I asked, through your valuable paper, for information upon the best valves, and their action for working steam hammers. From indifference, or want of knowledge, I did not get any reply from your correspondents. If "Essar" can, in a concise manner, give this information with illustration, I would thank him to do so. It would be appreciated by a greater number of users of hammers than by makers. The best valve and its motion that I know of wastes a great amount of steam. If "Essar's" knowledge of valves is practical, and especially if he can suggest improvement, I hope he or any of your correspondents will favour us with it through the Mechanic. But do not waste the paper by giving borrowed knowledge from exploded ideas.—E. Turner

[56025.] — **Trueing Grindstone. — Patent Law.**—"Nun. Dor." is very hard on me. I see that I transposed the words of the patent, and said, "Make, use, vend, and exercise." The words of the patent are, "Make, use, exercise, and vend," and occur in the granting part, which also in its language is also a prohibition. The words are:—"Victoria," &c., &c. "We, of our special grace," &c., &c., "do, by these presents, for us, our heirs and successors, *give* and *grant* unto the said patentee our especial license, full power, *sole privilege*, and authority that the said patentee, by himself, his agents, or licensees, *and no others*, may at all times *make, use, exercise, and vend* the said invention within," &c., &c., "and that the said patentee shall have and enjoy the whole profit and advantage from time to time accruing by reason of his said invention during," &c., &c. "And to the end," &c. Then follows the further prohibition, as quoted by "Nun. Dor." Now, one of two things must have happened—1st, Either "Nun. Dor." must have been splitting one of his hairs rubbed off by the cap he found to fit so well; 2nd, or "Nun. Dor." must have carelessly read the patent, and omitted to see the words I have given, or at least have failed to see their true import. Moral.—When correcting another, always be as sure as possible that you are yourself right. This I try, when writing, to do; but I am conscious that I often fail.—Z. Y. X.

[56032.]—**Enamelling Steam-Gauge Dials.**—There is nothing special in this work, except that the dials must be enamelled, not painted. The dials are covered with frit, made of, say, red lead 8, calcined borax 1, powdered flint glass 6, powdered flints 4, which are fused together for about 12 hours and poured into water. They are then reduced to powder, mixed to a paste with water or other suitable liquid, spread on the dials, and fired. The figures are usually put in with oil of lavender and vegetable black. If you really intend to do such work yourself, look up back numbers. There is a good article on enamelling in colours in No. 952.—Essar.

[56034.]—**Boiler for Engine.**—This querist should look up back volumes. I think he will find what he wants in the last volume; but I hope, if he intends to use 50lb. pressure for his 1in. by 2in. cylinder, he will make the boiler very much more than strong enough.—Essar.

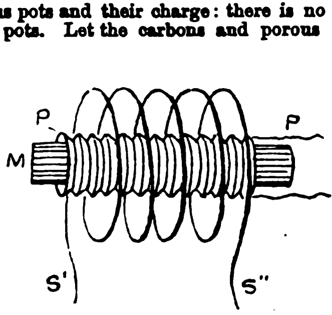
[56036.]—**Steam Boiler.**—It should evaporate 9lb. of water for each pound of coal consumed.—Essar.

[56041.]—**Gun-Metal** is a bronze usually composed of copper, tin, and zinc. Cast gun-metal (copper 8 parts, tin 1 part): specific gravity, 8·153; weight of a cubic foot, 509½lb.; weight of a bar 1ft. long and 1in. square, 3·54lb. (Tredgold); expands in length 1° of heat $\frac{1}{99090}$ (Smeaton) will bear on a square inch, with permanent alteration, 10,000lb.; and an extension in length $\frac{1}{980}$ weight of a modulus of elasticity for a base 1in. square, 9·873·000lb.; height of modulus of elasticity, 2·790·000ft.; modulus of resilience, and specific resilience not determined (Tredgold). Compared with cast iron as unity, its strength is 0·65; its extensibility, 1·25; and stiffness, 0·535.—J. C.

[56041.]—**Gun-Metal.**—I observe (p. 130) that "Z. Y. X." still doubts whether iron forms any part of "true gun-metal," and as the question thus turns on what is "true gun-metal," I confess I cannot help him, for I know of no authoritative decision as to what is and what is not "gun-metal." I remember the Uchatius steel bronze and the Aich metal, which, as they were used for making cannon, were, I suppose, "true gun-metal"; but I am contented to leave that point for "Z. Y. X." to settle: probably he knows what is a "true gun-metal"—I do not. I imagined, from his questions on p. 66, that he was asking for information when he requested to know whether "Nun. Dor." was poking fun by suggesting that gun-metal is sometimes made of a mixture of copper, tin, zinc, and iron, and I replied by giving a few facts to show that the statement was not a "slip." I have something better to do than to dispute with "Z. Y. X." or anyone else, whether an alloy containing iron is or is not a gun-metal: all I know is that some alloys called gun-metal do contain iron, and I must leave it to "Z. Y. X." to determine whether they are properly so-called or not. I leave it to your readers to discover who is "poking fun" and who has made a "slip." It is not much of a "puzzle," but as we are all anxious to learn, perhaps "Z. Y. X." will now tell us what is a "true gun-metal," and explain what he meant by asking on p. 66, "Is it really the fact that these four metals can be melted together?"—Nun. Dor.

[56054.]—**Hardening Lock Springs.**—Make them a cherry red, and drop into water the same as any other steel goods. But is that what you want to know? Is it not that you want to get the spring temper? If so, you will find the process described over and over again.—Essar.

[56064.]—**Troublesome Battery.**—I am glad that Mr. Parsons finds the advice given some use, and I am sure the result will not be only temporary. Now I understand Mr. Parsons better as to the porous pots and their charge: there is no need of fresh pots. Let the carbons and porous cells be cleaned from the old charge: replace the carbon in the porous cell, and fill up with a mixture of four parts of black oxide of manganese, and one part of powdered gas carbon, to which has been added a little strong ammonia. It was the charge, and not the pots, which was at fault in my opinion, unless the junction of the binding screws with the carbon was so dirty that no current could pass. Try to remedy this first, and if no better result is obtained proceed as above. 2nd. As to where to attach the handles in a shocking coil, in the annexed diagram P being the primary coil and S'S" the terminals of the secondary coil, these terminals must be brought to binding screws on the coil base, and the handles from which the shock is obtained connected to them. Yes, the core does come out; the secondary current being then weakest, and I would therefore advise Mr. Parsons to actuate his contact breaker by a small electro-magnet separate from the core M. There is no objection to your using iron pipe for the case to the core, only you are then making the magnet larger, for the iron pipe will become magnetised; but it will act all right. A battery of the size quoted should work the coil. Two layers of primary wire are sufficient, because the secondary wire must not be removed too far from the core on account of the influence it exerts on the secondary current while a magnet. About ten or twelve layers of secondary will be sufficient.—J. Kean, Northampton.



[56067.]—**Embossing on Brass.**—A mixture of pitch and resin is used for the pitch-block. Thickness of brass about 1-30th of an inch, or more if you like.—Nun. Dor.

[56072.]—**Road Locomotive.**—This query is answered by saying: Yes; it is quite practicable, and will, no doubt, be done when required.—T. M.

[56082.]—**Telephone Transmitter.**—"T." should look up the last few volumes of this journal, where he will find valuable information from Mr. Strangways, Mr. F. Dowling, and others, who describe various forms of transmitters wherein the carbon is adjusted as in the Blake transmitter. This form is the most difficult to make, so I should suggest the Johnson or Crossley form, in which pointed pencils of carbon are loosely fixed into blocks of carbon, in which blocks are small cavities for the ends of these carbon pencils. The blocks are fixed to the diaphragm. The carbon in these requires no adjusting. If, however, the distance be not more than one mile, I would advise the use of the Hunning's form of transmitter, which is the simplest to construct, and requires no induction coil. All these forms can be easily got into the space you mention. If you require more information I shall be pleased to assist. The patents of the above are all held by the United Telephone Company, so it behoves you to look out for legal squalls.—John E. Chaster.

[56096.]—**Amalgamating Zincs.**—The falling off of the current from Daniell cell is owing to either complete saturation of the liquid surrounding the zinc, or insufficient supply of sulphate of copper. The Daniell cell can be set up in different ways. If the zinc be in a dilute solution of sulphuric acid, it is necessary to amalgamate the zinc; but if, as is generally the case when constancy is required, the zinc is surrounded by some such half-saturated solution of a neutral salt as, for instance, salt or sulphate of zinc, amalgamation is not only unnecessary, but harmful, in that it assists the local action caused by the endosmose of the solution of sulphate of copper through the porous partition, which deposits metallic copper on the zinc. In this case, if the zinc be amalgamated, the metallic copper also combines with the mercury and the zinc, forming an alloy, whereas, if unamalgamated, the copper does not combine with the zinc. Presuming, however, that the zinc is in an acid solution, the best method to amalgamate is to steep the zincs in a solution of caustic soda, which is better used warm. This removes the grease, which always adheres more or less to new zinc; then thoroughly wash in water to remove any caustic soda. They may then be rubbed over with a diluted solution of sulphuric acid contained in a shallow vessel, in which is also a little mercury, taking care to flood the mercury over the zinc. A better plan, I find, when dealing with a quantity, is to plunge them in a solution of sulphate of mercury, and, lastly, mercury alone, then allowing to drain. The mercury you have would appear to be all right, seeing that it leaves no "tail."—John E. Chaster.

[56103.]—**Electric Accumulator.**—If "C. S. B." wishes to court trouble, expense, and disaster, he can do so with certainty by using the combination he proposes. The Daniell cell requires daily attention, and the Leclanché is of no value for working on a closed circuit for any length of time. There is no battery known that would work continuously for 29 days without attention. Moreover the accumulator would give out an exceedingly small percentage of the energy put in, owing to leakage and other causes. As it is a matter of dissolving zinc in any event to obtain your power, you would do far better by having some form of bichromate battery that will give you the power whenever you require it, by simply depressing a lever. Such a battery has been patented by Mr. R. A. Lee, of 76, High Holborn, which is automatic in its action, the elements rising out of the liquid by the gravitation of the cells. For the solution to use, see my reply to 55986, which, by a printer's error in "E. M." for 27th ult., is numbered 55916.—John E. Chaster.

[56110.]—**Mill Bills.**—As "P. M." has received nothing better, I have a recipe for hardening and tempering mill bills, formerly used and given in this paper many years ago by one of the best millers in the kingdom. If "P. M." likes I will look it up, and he can have it for 2d. postage from—HINCKLEY MAN.

[56112.]—**Chemical.**—Arsenic occurs in wall-papers, &c., in the green pigment, as either Scheele's green (cupric arsenite) or Schweinfurth green (cupric arsenite and acetate). 1st method. Finely divide the article to be examined and place in a small porcelain vessel. Add strong HCl and $KClO_3$. Place on water bath and add occasionally a crystal of $KClO_3$. Lastly, evaporate to dryness to remove any free Cl. The residue is dissolved with $H_2O$, adding a little $H_2SO_4$ and examined in a Marsh's apparatus as described by Mr. Keen in his reply to you. 2nd. Finely divided substance to be allowed to stand in cold strong HCl for one hour, then gently heated. A small portion of this liquid placed in test tube with strong solution of stannous chloride or piece of pure tin foil. If As be present, a brown colouration or brownish-black ppt. will be the result. 3rd method. The simplest and most ready test is to place the substance in a test-tube and add ammonia. After a time a blue colouration will result if As be present, owing to the copper contained in the arsenical greens, and to which attention is called. Verify by methods 1 and 2.—JOHN E. CHASTER.

[56112.]—**Arsenical Testing.**—The test given by "Stud.Inst.C.E." will only succeed with certain compounds of arsenic, notably with Scheele's green, but it would fail with the sulphide of arsenic. In this form the presence of arsenic is best ascertained by scraping off some of the pigment from the paper, carefully avoiding the presence of organic matter, *thoroughly drying* by gentle heat, and heating in a test-tube with *perfectly dry* carbonate of sodium and cyanide of potassium in equal parts, when arsenic will produce a bright metallic ring in the tube. Absolute dryness is essential to the success of the process.—PI.

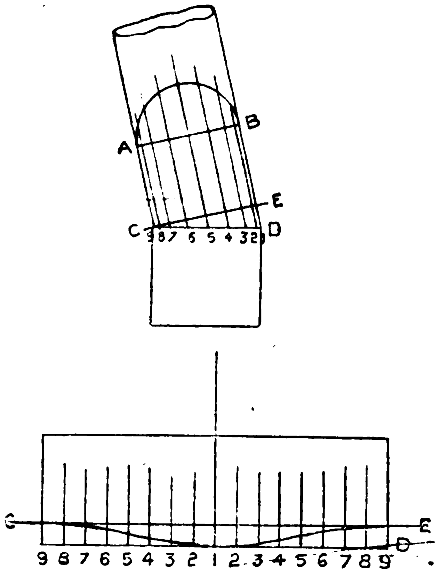
[56115.]—**Gilding Watch Movements.**—To prepare watch-plates for gilding: Take a smooth flat piece of bluestone, place a cork in vice, and a pan of clean, cold water beneath. Place your work on cork, and hold lightly with left fore-finger and thumb; with right, rub stone across, keeping as wet as possible and shifting work gradually round, to keep it flat; this to get all scratches and file-marks out. The "nice matted surface" is a trouble to the amateur. I have tried to get it in vain, the plates being invariably smooth and the stone marks showing. The gilders, I believe, heat the plates to a dull red, and plunge momentarily in dilute nitrous acid. As this softens the brass, it is objectionable. Mr. Watt, in his "Electro-Metallurgy," gives the following:—"First, place the work in a weak solution of caustic potash for a few minutes, then rinse in cold water; dip in nitrous acid for an instant, then place immediately in cold water, rinse in hot, and place in bath for a few seconds. When gilt sufficiently rinse in hot water, scratch-brush, rinse, and return to bath for an instant to give good colour; rinse in hot water and place in boxwood sawdust to dry." From the above you will see the necessity of being clean with work. The pivot holes are untouched, and if your fingers, ale, and brush are clean (with copious stream of ale) you will have no scratches.—YOUNKER.

[56117.]—**Pacinotti Ring.**—The method of winding a Gramme ring, as sketched by Mr. Bottone, is rather of the Brush arrangement, and surely Mr. B. is in error in describing the collecting slips as a "commutator." Such an arrangement is a collector, according to the idea of—ELECTRA.

[56142.]—**Wheatstone's Bridge.**—I desire to thank "A.S.T.E." for his kind reply and offer of further assistance, which I hasten to avail myself of. Will he say lengths, diameter, and approximate resistance of the carbon-rod most easily obtainable. I have about 3lb. various sizes uninsulated German-silver wire, which I purpose making up into coils as described on page 307, Vol. XXXV. The bridge described in my query has four openings, $\frac{A\ \ B}{C\ \ D}$. Suppose I require to make up a copy of a resistance coil: I have bought, say, 5 ohms. I put this in A; into C I insert the length of wire, increasing or decreasing till I balance. How do I fill up B and D again? I have an ohm from which I wish to produce 10 ohms. I insert the ohm in A, the wire to be balanced as 10 ohms in C. Should I be doing right by inserting 1 decimètre of No. 18 German silver wire in B and 1 mètre in D, and then shifting C till I balance? This, seems to me, ought to be 10 ohms. Will "A.S.T.E." kindly say if I am on right tack? If so, I will start making the apparatus accordingly.—J. O. M.

[56183.]—**Force in Motion.**—"Acier," in answer to the above query last week, says the man will drag the boy by exerting a fraction more effort than the boy is capable of doing, and the strain on the rope is equal to that of the boy only. Will "Acier" kindly tell us what becomes of the fraction?—say about one pound—as I cannot help fancying that it has just a little to do with the strain on the rope, and oblige—A COUNTRY CHIP?

[56132.]—**Cutting Pipes.**—I suppose it is for a chimney for marine boiler. Mark your chimney down full size, or to scale A B C D; draw a circle



as shown in sketch A B, divide this into as many parts as you like round the circle, then make a line, down the centre, and carry the other lines down parallel. Number these as shown, 1 2 3 4 5 6 7 8 9, lay your plates down, then divide them into as many lines as you have in A B. Beginning from the centre each way, strike line C E, then measure the distance on each line from E D; make the lines on plates C D the same. You will have to make the bottom part equal in circumference to C D when the development is cut.—BOILER MAKER, Sunderland.

[56156.]—**Chemical Action in the Bichromate Battery.**—To "J. T. S."—The complete reaction of the bichromate battery is as follows:

$$\underset{295}{K_2Cr_2O_7} + \underset{195}{3Zn} + \underset{686}{7H_2SO_4} = \underset{567}{K_2SO_4Cr_2 3SO_4} + \underset{483}{3ZnSO_4} + \underset{126}{7H_2O}$$

or for every pound of zinc dissolved there is required 1·5lb. of bichromate of potash, and 3·56lb. of sulphuric acid. There will be yielded by the battery, as by-products, 5·1lb. of chrome alum, containing 43 per cent. of $H_2O$, and 4·4lb. of sulphate of zinc, containing 43 per cent. of $H_2O$. The difficulty would be to crystallise out the chrome alum from the sulphate of zinc. The solution becomes a dark green, owing to the formation of chrome alum. When the chrome alum is crystallised out the salt is a dark purple. Chrome alum has a market value in Lancashire, and is an article manufactured. The market is very limited, however, and this also applies to sulphate of zinc; so that if these two substances be ever collected on anything like a large scale, they would immediately glut the market.—JOHN E. CHASTER.

[56207.]—**Clock Repairing.**—I imagine that we have in our house a clock very similar to that of "Many Years' Subscriber's"; and, although it is now about 42 years old, keeps excellent time, and all that has been done to it during this time is that a couple of the holes, through wear, have been closed with simply a few blows of a light hammer; but chiefly (and this is why I write) the escapement wheel has been moved on its axle, or arbor, three times to bring the teeth to bear upon a new part of the escapement pallets; for although only a soft brass wheel, it has cut a deep channel, first in the centre of the hard steel pallets, then to one side, and now upon the second side. Let "M. W. S." try this simple plan before resorting to more drastic measures, such as refacing with watch-spring the pallets; also examine more carefully the pivots and holes of the escapement-wheel that they have no play, but fit true in the plates.—CÆSAR.

[56207.]—**Clock Repairing.**—You have an eight-day clock which stops. The clockmakers tell you it is worn out. Probably they are correct, although you doubt their assertion. You do not state whether it is of English or American make—whether striking or not. I assume it is an American striking one. Remove the movement from the case, take out the pallets or verge, and allow it to run down gently, by placing one finger upon the third wheel. Do same with striking train. Take out plate-pillar pins, and lift off top plate; take out all wheels, &c. Clean and polish both plates, also the holes, with peg wood; clean and polish every wheel and pinion. Now examine every bush with its pinion in. Notice which are worn egg-shaped, or too large. Make these a trifle larger, and into each one insert a bouchon firmly. Examine pinion leaves; if any are loose or worn, replace the loose ones with new wire, or the worn ones may be scraped with a graver. Examine escape-wheel teeth. If any are budged, bent, or not of uniform thickness, straighten the bent ones with fine pliers, and file up the budged ones with fine file from the back. Have every tooth of the same angle, length, and thickness, particularly at the points. Examine pallets; if these are pitted, rub them smooth with oil-stone slip. If too far gone, replace with new one of same size. Put up the movement, place on the pallets, adjust the pendulum-spring to be equal in beat. Oil every bush with one drop of oil, not omitting the pallet-tail slot, through which the pendulum-wire passes. Wind up, and the clock will go if you have followed out the above directions carefully, and properly executed the usual repairs.—FRED. HUNT, Widnes-road, Widnes.

[56216.]—**L. & S. W. Express Engines.**—There was a misprint in my letter on L. and S. W. Express Engines on p. 35. The length of tubes is 10ft. 6$\frac{5}{16}$in., not 10ft. 0$\frac{5}{16}$in. as stated. This will make the heating surface as given, correct. I am obliged to "E. M." for working out the figures, as I should not otherwise have detected the misprint.—METEOR.

[56239.]—**Acid Filter.**—Four years ago, having to fit up plant for purifying $H_2SO_4$, manufactured from Spanish ore, containing a large percentage of arsenic, I had the same trouble to contend with as "F. G. S." I tried asbestos cloth, which was an utter failure: it was impossible to remove the precipitate, although removed and washed each time the asbestos cloth was used, it soon became quite rotten and worthless. I then got a wood tank made, about 6ft. long by 4ft. wide, and lined it with lead. I placed in the bottom small boler flints for the first layer and afterwards crushed flints of different degrees of fineness, covering the whole with a perforated sheet of lead punched full of small holes not more than ¼in. diameter, over which I placed a thin layer of white sand (not acted upon by the acid). The precipitate may be scraped off with sand with but little labour. A filter of this description will last for a great many years. A little sand must be replaced after removing the precipitate.—CHEMICAL WORK.

[56240.]—**Tug.**—The hull of the dimensions stated could be made into a creditable racer if fitted with the following:—Boiler, cylindrical (no steam dome), riveted, 15in. long by 8in. diameter, of 18 Stubbs's W.G. thickness; firebox, 6in. by 5½in. diameter at mouth to 5in. at tube plate; top of firebox to be flattened to a radius of 6in., the distance from crown to shell to be 1¾in. Tubes, brass, 40 in number, $\frac{7}{16}$in. dia.; thickness of metal in tubes, 26 to 30 Stubbs's W.G.; length about 9¼in., or sufficient to extend from tube plate in firebox to ditto at smokebox, leaving about ⅛in. projecting, which may or may not be swelled out. Smokebox must be arranged to take off readily for cleaning tubes. Have two funnels 1¾in. dia., the forward funnel to have a damper, and to fit in a tube 1¾in. diameter extending from centre of firebox crown to shell. This, you will find, is an immense advantage and convenience when getting up steam, and for stoking with small coke and charcoal when racing. This boiler, properly riveted, must stand a test of 120lb. cold water, and work at 60lb. All joints should be tinned before putting together, and sweated after riveting up. Engine.—A pair slide-valve cylinders, 1¼in. diameter, 1¼in. stroke, fitted with a feed pump; ¼in. plunger, ½in. stroke, and brass ball valves (no other valves work so well at this pressure). Take steam from boiler by a ¼in. bore brass pipe, with stopcock connected to a tripping gear fore and aft for stopping and starting. Carry exhaust by a pipe $\frac{1}{16}$in. larger than steam pipe to after funnel, the nozzle to point straight up the centre to get full benefit of blast. Connect propeller shaft direct to engine shaft; there is no necessity for gearing. A hand-feed pump forward is absolutely necessary, and this I find must be arranged to pump without valves if to be depended upon. Spring safety valve to be ⅜in. diam. with a knife-edge seating (a mitre seating is not to be thought of if life is worth anything), spring to have a pull of 7lb.; water gauge should have a glass about ⅜in. diam. external, and should be long enough to show water level from crown of firebox to shell of boiler. With the ordinary gauge-glass fittings, as shown in model shops, it is not always convenient to fix them on the boiler to show as much, and a modified form is now used by nearly all model steamboat sailers in the London parks. As to the propeller, the size, pitch, and number of blades is entirely a matter for experiment in these models. A screw of low pitch lets the feed-water gain, and one of high pitch, or too large in diameter, lets the feed come in too slow. You might try several screws first, and fix on the one which propels at the fastest rate, and adjust the stroke of feed-pump to keep the water in boiler at one level. If water should then go low, a few strokes of the hand-pump will soon bring it up. Details of boiler, engine, or fittings I will give you with pleasure if required.—S. Austel.

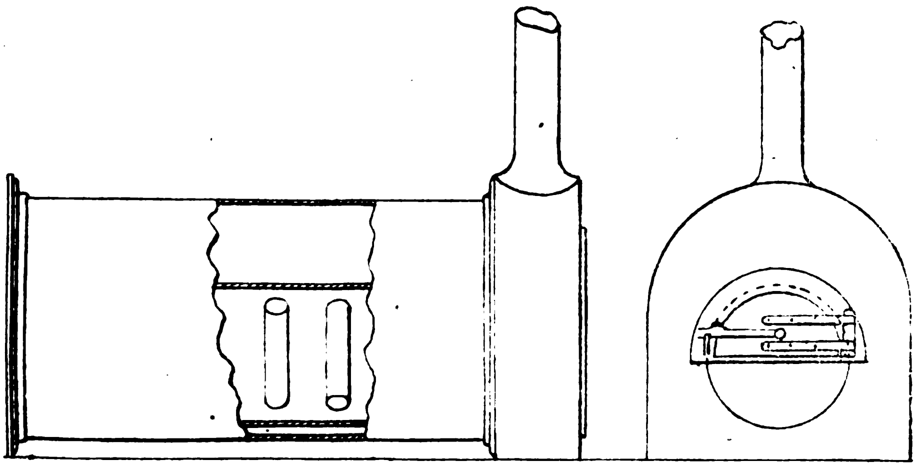
[56242.] — **Relation between E.M.F. of Dynamos and their Size and Speed.**—While thanking Mr. Eugene Brown for his answer to my query, I am sorry to have to say that the said answer does not contain the information for which I ask. I wish to know not merely the rate of variation of the E.M.F., with variations of speed, field-intensity, and turns, but to get some definite quantitative results for given values of these variables. Can Mr. Brown or Mr. Bottone send detailed particulars of dynamos, together with statements of E.M.F. at various speeds?—Wm. John Grey, F.C.S., analytical chemist, Newcastle-upon-Tyne.

[56243.]— **Fuses for Projectiles.**—To "Garrison Gunner."—Very many thanks for your kind and very complete answer to my query. I shall not ask you to take the trouble of looking up the "changes in war stores," for the information you have given is enough as it stands. Your description of the new fuses has so much interested me, that I am writing to the Director of Artillery for permission to procure from the R.L. drawings of the fuses you mentioned. And I presume that the drawings, like all good drawings, will explain themselves.—Ex-Garrison Gunner.

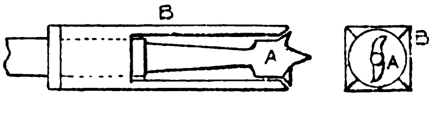
[56250.] — **Engine-Making at Home.**—I am in a fix this time, for I don't know whether I have to make the bed-plate out of the solid mahogany or make it in pieces; but I am very sorry for troubling you, but if you could give me suitable sizes for a good working model, I will take the parts in detail.—Snooks.

[56269.]— **Collimation.** — To "Rosicrucian." —By Cipher 51, wire I. is distant from the collimation centre 29·37s. (reduced to equator). Wire I. is distant from the main wire 27·8s. Hence the main wire is distant 1·57s. from the collimation centre. Similarly wire II. is distant from the main 13·8s., and from the collimation centre 15·47s., and hence the main wire is distant 1·67s. from the collimation centre. The mean of these two determinations is 1·62s. The collimation centre is on the side of the main wire away from wires I. and II. All stars transiting the wires in the order given for δ Orionis require the correction 1·62s. × sec. declination. The wire intervals, however, cannot be determined from a single transit; nor can the collimation be inferred from the observation of a close polar with reversed positions of the transit axis, unless the azimuth error of the instrument is approximately known, as the star might not be moving in a direction perpendicular to the wires. The position of the mean wire with respect to the individual wires (wire-intervals, as they are called) is usually determined from the transits of three or four hundred stars.—G. L. T.

[56271.] — **Portable Engine.** — The simplest form is that shown in sketch herewith. It is a modified Cornish boiler. A shell plate with internal fire tube; dimensions should be—length, 24in.; diameter of shell, 12in.; diameter of furnace tube, 7in., with six cross water tubes in flue beyond the bridge, these tubes being 1in. internal bore. The tubes should be set to cross one another, as shown in part broken away. The shell might be, in your case, of iron $\frac{3}{32}$in. thick, and the furnace tube the same, the smokebox being of lighter metal still. The end view will show how the plate is carried down to form a stand for boiler, and the smokebox the same. Very light angle iron can be used to secure the plates of shell and furnace to the ends, and, if put on as shown, no difficulty will be found, because the angle ring being welded to the shell, the last ring of rivets are all external, and can be got at both sides. I trust the drawing will make all clear to you; if not, write again.—Invicta.



[56285.]—**Drilling Square Hole.**—George A. Walton may, perhaps, be seeking for some such tool as the above (copied from Luke Herbert's "Engineers' and Mechanics' Encyclopædia," 1837). A is a centre-bit working in a sort of cast-steel squared box with chisel edges B. This latter must, of course, be prevented from turning round with the centre-bit, and it is easy to see how this could be done in the lathe, either by holding it or resting its lower side on some flat surface, whilst both borer and hollow square were forced forward into the wood. The square cutter has openings at the side for the discharge of the chips. Mr. Thomas Hancock is stated to be the inventor.—Richard Inwards.



[56290.]—**Water Gauge.**—In my practice I have met with at least one instance wherein a vacuum in the boiler caused the water to rise up and fill the glass gauge without increasing the quantity of water. This peculiar action is like carrying oneself in a bucket: it is nevertheless a fact though unexplained. Remedy—open any one of the cocks about the steam space sufficient for a moderate escape of steam, and leave it thus for the night. The air will rush in and prevent a vacuum forming. This plan should be strictly followed when steam is allowed to cool itself down in any boiler; the vacuum, or external pressure of 14lb. to 15lb., would have little chance of straining the riveted seams in the direction opposite to that of the general working strain. The advantages are obvious.—Yama.

[56294.]—**Chemical.**—The decomposition which takes place when chlorine is passed into milk of lime, and indeed into other metallic hydrates, is not thoroughly understood; but chlorides and hypochlorites are supposed to be formed as in the equation—

$$2Cl_2 + 2Ca2HO = CaCl_2Ca2ClO + 2H_2O.$$

—Epworth.

[56301.]—**Flowerpots.**—I have used plumbago well-rubbed on the moulds for ornamental bricks, tiles, &c., made from plastic clays, and they leave the moulds well.—M. W. S.

[56309.]—**Spica and the Star of the Magi.** —If Mr. Arkwright desires some curious information on the above, and the constellations generally, as typifying fundamental Bible truths, he should consult "The Testimony of the Stars," an abridgement of the late Miss Rolleston's "Mazzaroth," and published by Rivington's, London.—Arthur Mee.

[56316.] — **Eight-inch Spark Coil.** — The spark became more continuous, and its thickness sensibly increased, when cells of a larger size were used. In order, however, to obtain the best effects which the stronger current was capable of exciting, it was found necessary to increase the condenser surface; and after the required alteration had been made, the coil no longer worked satisfactorily with the small cells first employed. This was precisely what my experience had led me to expect. The adjustment of the condenser is so delicate a matter, that the addition or removal of a single pair of foils produces a surprising difference when the right capacity is approached, whilst the length and frequency, colour and thickness, of the discharge, and even the sound which it makes in breaking through the air, may be modified by material changes of the condenser capacity. If the capacity be sufficiently increased the spark may be extinguished, the large condenser (say of from seven to ten micro-farads' capacity, as an extreme case) producing the effect of a low-resistance shunt between the contacts of the break, and absorbing the current so completely that there is practically no interruption of the circuit when the points are opened—acting, in fact, much as the earth-connections of a telegraphic system are supposed to act by a certain school of thinkers. Considerable alterations of the battery-power give rise to effects similar in kind, although limited in degree, and the composition of the core also exercises an immense influence on the character of the discharge. In the course of some rambling experiments upon this influence of the core, I had the misfortune to mechanically injure the coil described in my letter of January the 4th, 1884, and a growing internal leakage was set up, which made it necessary to unwind the secondary wire. During the progress of this task, I detected several faint indications of the passage of sparks through the paraffined-paper partitions, and in one of them, at a spot near the centre of the coil, two very large holes had been burnt so as to produce a "short-circuit." The edges of the holes were charred and blackened, and altogether the disc presented a significant and picturesque appearance. In rewinding I adopted thin sheet ebonite for the material of the partitions, or discs; and followed a plan to which I had been led by experience, gained after the completion of the original 8in. spark coil, and chiefly in connection with the construction of a little instrument which, having only two and a quarter miles of secondary wire, gives a continuous 4in. spark with a battery power of five one-pint Grove cells; that is to say, I considerably reduced the number of the compartments, made them wider and a little deeper, and increased the thickness of the insulating covering of the wire, using three coatings of silk upon a proportion of the secondary. The rewound coil excels its precedessor in all respects save one: an additional cell is required to work it, because the altered build carries the bulk of the secondary rather further away from the core. Unless Mr. Harcourt is willing to expend what many students would deem a large sum, I should advise him, in the absence of a better model, to copy closely my original 8in. coil (to which he refers), using single-covered wire, but substituting ebonite discs for the discs of paraffined paper. Suitable sheet ebonite—No. 24, B.W.G.—can be obtained from the Silvertown Indiarubber Company, at a cost of about seven shillings per pound, and a couple of pounds would probably suffice for the purpose. I shall be glad to help Mr. Harcourt with any further information which is within the limits of my experience.—Ernest Baugh, Haverfordwest, Pem.

[56311.]—**Chemical.**—According to the equation, $2NaNO_3 + H_2SO_4 = 2HNO_3 + Na_2SO_4$. 170 parts of sodium nitrate require 98 parts of sulphuric acid to produce 126 parts of nitric acid. Therefore one ton of sodium nitrate will produce $\frac{2240 \times 63}{85} = 1,660\frac{1}{4}$lb. of pure nitric acid; but acid of sp. gr. 1·42 only contains 70 per cent. of pure nitric acid, so that we must multiply $1,660\frac{1}{4}$ by $\frac{100}{70}$ to obtain the quantity of nitric acid, gravity 1·42, which can be obtained, which is 2,371·8lb. Again, 170lb. of sodium nitrate require 98lb. of sulphuric acid; therefore 2,240lb. will require $\frac{2,240 \times 98}{170} = 1,291·3$lb. of acid of 1·842 gravity, this being the gravity of pure sulphuric acid. 170lb. sodium nitrate will produce 261lb. of barium nitrate. $2NaNO_3 = Ba2NO_3$, so that one ton will make $\frac{2,240 \times 261}{170} = 3,439$lb of barium nitrate.—George H. Hurst, Salford.

[56311.]—**Chemical.** — This query is rather "mixed"; assuming, however, that "soda" really means nitrate of soda, the reaction for the production of nitric acid is

$$\begin{array}{ccccccccc} 2NaNO_3 & + & H_2SO_4 & = & 2HNO_3 & + & Na_2SO_4 & & \\ 170 & & 98 & & 126 & & 142 & & 268 \end{array}$$

from which we get

$$170 : 98 :: 1 : x = ·576 \text{ ton } H_2SO_4$$

as the theoretical quantity needed to decompose one ton of Chili saltpetre. The quantity of nitric acid sp.gr. 1·530 theoretically yielded, is given by the proportion

$$170 : 126 :: 1 : x = ·741 \text{ ton}$$

but the acid at 1·42 sp.gr. contains only 70 per cent. of $HNO_3$, so the yield of that acid would be 1·06 ton. In practice 240 parts of sulphuric acid are used to decompose 305 parts of sodium nitrate, and yield 363 parts of acid at 55 per cent. $HNO_3$. Presuming that the barium nitrate is produced by double decomposition the theoretical quantity is 1·535 ton per ton of Chili saltpetre.—Wm. John Grey, F.C.S., analytical chemist, Newcastle-upon-Tyne.

[56313.]—**Cylinder.**—There are plenty of alloys I could mention which would harden the metal; but the real question is the getting a brassfounder to melt so small a special quantity as your cylinder would need. If you have a gun-metal cylinder at all, the ordinary mixture will serve you as well as any special one. The small size of your cylinder does not necessitate its being of specially hard metal. Thickness of sides of cylinder may be $\frac{3}{8}$in.; flanges, say, $\frac{1}{4}$in.—Invicta.

[56317.]—**Royal Exhibitions and Scholarships.**—I cannot give "Eldhin" much information as to future prospects, and so must leave this query to others; but I may say that, unless he really cares for science, he would be foolish to try for these positions merely as commercial speculations. There are so many now who love science for herself, that he who only woos her for what she may give him has but a wretched chance.—Wm. John Grey, F.C.S., analytical chemist, Newcastle-upon-Tyne.

[56323.] — **Vegetarianism.** — In reply to "A Regular Reader" in your current number, I may state that I shall be glad to send him a packet of literature containing a small cookery book and other information which will help him in reforming his diet. The *Food Reform Magazine* will be found to contain a list of publications upon vegetarianism. The packet I have mentioned will be sent upon receipt of a stamped and directed envelope from "A Regular Reader," or anyone seeking information upon food reform.—F. P. Doremus, Hon. Secretary National Food Reform Society, Finsbury-square Buildings, 1 and 2, Chiswell-street, E.C.

[56324.] — **Sunlight at Great Depths.**—Thomson, in his "Depths of the Sea," gives no exact figures; but has this remark: "It would appear that the rays capable of affecting a delicate photographic film are very rapidly cut off, their effect being imperceptible at the depth of only a few fathoms."—Arthur Mee.

[56326.]—**Sketching.**—A camera lucida would assist "Artist" in sketching; but though portable itself, it must in use be fixed to a level table. It is sometimes employed in determining the leading points and lines of elaborate buildings. Last year at Squire's, the artist's colourman, in Oxford-street, I saw an ingenious French plan, called "L'Orthorama," designed to help the unskilled draughtsman. The part which enables the sketcher to obtain a correct outline consists of a light wooden frame, on which is stretched a sheet of black gauze. This stands vertically between the eye and the view to be taken. At right angles to the frame is a sliding wooden rod, to which is attached the eyehole. The sketcher adjusts the distance of the eyehole from the frame so as to embrace the view he desires to draw, then keeping his eye fixed at the eyehole, he traces with white chalk the outline of the view on the gauze. When finished, or a sufficient number of points are secured, he places the gauze on his canvas, or paper, and goes over the white lines with charcoal. The abraded charcoal passes through the gauze, and leaves a dark outline on the canvas, or other material. The instrument, including a stool, three legs to screw into the containing box, which then serves as an easel, is, when packed up, of the size of an ordinary French wooden oil-colour box, and costs, I think, about £2. After all, these are both purely mechanical ways of obtaining a sketch. Would it not be better for "Artist" to practise drawing till he can dispense with such appliances? The pencil held at arm's length, at right angles to the line of sight, will then enable him, by moving his thumb till the end and his nail subtend the same angle as the distant objects, to obtain with sufficient accuracy all the relative dimensions he may have to represent.—Eye-witness.

[56326.]—**Sketching.**—I believe such an instrument as "Artist" desires is described in a little book, "Systematic Drawing and Shading," published by Cassell.—Arthur Mee.

[56327.]—**Transferring Pictures to Glass.**—I do not know if the following is what "C. P." wants; but it is the plan adopted by framers for large pictures, the price for framing which will not pay for a stretcher. Damp the picture thoroughly from the back, then lay face upwards upon a table, having the glass (previously cleaned) cut of a size to allow about a quarter of an inch all round to overlap. It will save trouble at the corners to cut off small pieces. Place the glass upon the picture nice and straight, then paste the edges both of paper and glass with a strong paste (shoemaker's) and stick down on to the front of glass. In drying this will tighten up to, and look as if "painted on, the glass." When dry go round with a sharp knife, cutting off to within an eighth of an inch of the edge, which will hold it quite tight. The rebate of frame will hide the remainder.—R. H.

[56328.]—**Vertical Boiler.**—The only practical way is to drill a small hole through the suspected plate; it need not be more than, say, $\frac{1}{4}$in. diam. At 60lb. pressure you must be careful. Vertical boilers of the common construction expose the funnel tube, where it passes through the steam space, to the hot gases from the furnace, with the result that angle iron, ring, and the plates round suffer not only from the intense heat, but also from the continued contraction and expansion. By no means despise the visible evidence of corrosion and oxidation, but see at once how the plates are; leave nothing in a steam boiler to *chance*.—Invicta.

[56329.]—**Crank Throw.**—Your lathe crank having a stroke equal to 5in., and your cylinder 6in., it would mean that you would have $\frac{1}{2}$in. clearance at each end of cylinder instead of a theoretical $\frac{1}{4}$in. or $\frac{3}{32}$in.; it will do all right; the only thing being that you neither get the full power out of the cylinder, and also that a small quantity of steam will be thrown to waste through the exhaust. I will at any time help you with great pleasure.—Invicta.

[56331.]—**Chimney Pipe.**—Have you tried a joint made with borings and cement, or an ordinary rust joint?—Invicta.

[56334.]—**Launch Engine.**—To "Invicta" and others.—Most assuredly you can nearly double the engine power as it is. We will assume that the two existing cylinders are utilised as high-pressure ones. And you then add a third cylinder, which you would use as a low-pressure one. If the pressure in the boiler be high enough, you should get a good result from such an arrangement. If you, as you should do, condense the exhaust from the low-pressure cylinder in a surface condenser, you would have a most efficient arrangement. The surface condenser need not be either a cumbrous or costly matter. And on this or any other point of detail I am always ready to help you or others.—Invicta.

[56334.]—**Launch Engine.**—I always find that if the exhaust is in any way retarded, that an engine loses a great deal of its power.—D. G. T.

[56335]—**Potter's Kiln.**—It is not stated of what quality of clay the terracotta is to be made—ferruginous clay, or of fireclay; nor the articles it is proposed to fire: thick blocks for architectural purposes, or thin vases, busts, and the like for indoor use. If the querist will define these points specifically, some of the readers of the "E.M." will doubtless endeavour to assist him with suggestions.—Pottery Tech.

[56338.]—**Pattern Making.**—If "Busby" has Nos. 983 and 985 in Vol. XXXVIII. of the "E. M." he will find instructions therein relative to the making of the principal patterns for a slide-rest. The leading screw for a 6in. lathe should be $1\frac{1}{4}$in. in diameter, and $\frac{1}{4}$in. pitch, neither square nor vee'd in section, but having the sides inclined at a slight angle. I don't quite understand your last query; but if you allude to the back-gear spindle, it is either thrown in and out of gear with a small eccentric and handle, or by being slipped endways, and kept from shifting by means of a pin. If you have an oblong hole, it appears as though the intention is to slide it backwards. The pinion for screw-cutting is put in the mandrel by being slid on a key feather slightly tapered.—J. H.

[56339.]—**Stops to Photo. Lens.**—"Gwent" says he does not know what the "equivalent focus" of his lens is! It is the distance of the optical centre from the ground glass, arrived at by measuring the size of the image on the glass as compared with the original, at a given distance. But unless "Gwent" wishes most accurately to compare his lens with some other, he may for practical purposes regard a point midway between the two lenses, when focussing for a distant object, as the equivalent focus. The value of the standard diaphragms referred to is that they have a relative aperture, which "Gwent" can easily prove if he will measure the diameters, and by squaring the diameters he will know the relative apertures, instead of making them of accidental sizes which have no definite relation one to the other.—A. Pumphrey.

[56341.]—**Cheap Gas.**—If "Glatton" will apply to Mr. A. Brotherhood, of 127, Redcliff-street, Bristol, I daresay he will give him particulars of the "Dowson" gas and apparatus, which costs 3d. per thousand cubic feet. He will also give you names of firms who are using it. I think Crossley Brothers use it in connection with the Otto gas-engine.—D. G. T.

[56341.]—**Cheap Gas.** — To "Invicta."—To mention names and addresses would be to break what I believe is a rule of this journal, and with which I entirely agree. If "Glatton" likes to ask any question through these pages, all the information I have is at his service, and if he likes to afford a channel by way of the Address Column, I would then in private give him names and addresses of makers, as also some information respecting the more recent improvements with which my apparatus is fitted. I might just mention that I am under the impression that the improvements in question are separate patents—not the property of the original patentee.—Invicta.

[56342.]—**Public Lighting.**—At Wimbledon "Surveyor" can see a good specimen of petroleum lighting, through inability to agree with the gas company, of about three years' duration, with about ten shillings per lamp per annum saved in the expenses of same.—A Country Chip.

[56342.]—**Public Lighting.**—There are at least several townships in Ireland lighted by a special form of lamp, the gas being produced from paraffin or petroleum in a small container forming part of the lamp-fitting itself. The system seems perfectly satisfactory, and works well enough. The lamps themselves are terribly dear—in fact, out of all reason. And this is, in my opinion, the reason why the apparatus I have in mind is not in more general use. For the reason stated in my reply to query 56341, I forbear to mention names; but will be happy to put "Surveyor" in connection with the makers if he so desires.—Invicta.

[56344.]—**Rubber Belting.**—Cut the ends at an angle of 45°, and overlap them twice the width of the belt. Lay the belt straight; mark the ends on to the belt, then split it in halves right up to each mark. Have some rubber solution at hand, and smear over all the joint; place the halves together, and press them with weights. Leave undisturbed until dry, which will be hastened by the operation being performed in a heated room. Rubber belts should not be cut narrower, because in doing so the selvage edge is removed. The best method of cutting is with knife and straightedge on a zinc plate.—Arefes.

[56346.]—**Sellers's Screw-Thread.**—In the American or Sellers's system of screw-threads the sides of the thread are inclined at 60°, and a depth equal to $\frac{1}{8}$ of the pitch is cut square off at top and bottom of the thread. The pitch is—

$$p = 0{\cdot}1\,d + {\cdot}025 \text{ nearly} \ldots\ldots\ldots\ldots \quad (1a)$$

$$d_1 = d - \frac{1{\cdot}299}{dn} = 0{\cdot}87\,d - {\cdot}03 \quad \ldots\ldots \quad (2a)$$

—Thomas L. Reid, Crewe.

[56350.]—**Electro-Plating.**—Nothing will prevent the silver peeling off your plated articles in their present condition. The time to prevent this is before immersing in depositing vat. Articles of copper, brass, or German silver must first be properly cleaned, then dipped into a solution of nitrate of mercury, or of cyanide of mercury and potassium; then well washed in water, and immediately suspended in depositing vat. If they are placed in the vat without this preparation, the deposited silver does not firmly adhere. Always regulate the current by the battery itself, raising or sinking the battery plates deeper in their liquids, as you wish to increase or decrease the quantity of metal deposited. If a hard, bright deposit is wanted, employ a current of small quantity and high intensity; but if the deposit is wanted soft and less coherent, employ greater quantity and less intensity. The time required for the process cannot be exactly determined, as it depends on the quantity of metal requiring to be deposited, battery power, size of articles, and the solution being in good working order; but you might safely keep the articles suspended till they appear well coated.—Bobadil.

[56352.]—**Lacquer for Lamp.**—I should think that you might effectually deal with the lamp as follows:—First, well clean the whole of the metal-work you wish to decorate, and be sure to remove all grease or oil. Now paint over as thinly as possible the metal-work with gold size, and just as it gets "tacky" brush over it with a flat camel-hair brush some bronze powder. You can get this of various shades, either copper or gold. Brush off all the superfluous bronze, and allow the work to thoroughly harden. When dry, say in 24 hours, give a coat of hard spirit or coach varnish. The effect will be to convert your lamp from a tin into apparently a brass or gilt one. If properly done, the appearance is exceedingly good.—Invicta.

**Intelligence of Tortoises.**—Anecdotes in the *Revue Scientifique* appear to show that these creatures must be credited with a considerable amount of intelligence. M. Boucard writes of one which lives in his garden, and, when called aloud by its name, "Laideron," would immediately run towards the voice with all the speed a tortoise can muster. The *Testudo mauritanica* of M. Boisse showed even more intelligence, learned to come when called by a hissing sound, followed its master like a little dog, relished caresses bestowed on its head and neck, gave gentle bites to show its affection, and would climb upon its master's boots or pull at his clothes to draw his attention.

# UNANSWERED QUERIES.

*The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.*

# QUERIES.

[56356.]—**Telephone Battery.**—Will some one inform me of the kind of battery used in telephone exchanges? I have been using Fuller's battery lately, but find it rather too expensive and troublesome.—Phono.

[56357.]—**Telephone Switch.**—Could anyone give me a rough drawing of the automatic switches in use by the Post Office, I believe, in some of their exchanges? It is inclosed in a square box with hinged cover under lock and key, the telephone suspended by a hook projecting underneath.—Phono.

[56358.]—**Chronic Cold.**—I have suffered from my youth upwards from a chronic cold in the head. I have been to one of the first doctors in London, but he has failed to cure me. His first recipe was cod-liver oil and iron, which I took for a couple of years, and then an injection of Tidman's sea salt to clear the nostrils. If any reader has therefore had some practical experience and cure in the above, he would indeed be a friend in need to—Ora et Labora.

[56359.]—**Coiling Thin Metal Strips.**—Will any of "ours" kindly inform me how to coil German silver strips? They are different widths, mostly under ½in. metal size 1, and are flat on the front with square hollow edge each side. They must be round, 2in. diameter, with edges inside. I have tried winding, but find they sink in on the front. Having seen them finished thinner and also smaller, perfect, any hints as to how to make them will be thankfully received.—Urgent.

[56360.]—**Tandem Bicycle.**—Will some bicycle friend kindly assist me in following? I have made a tandem bicycle after the Rucker fashion; the wheels 50in. and 52in.; the connection, inch square iron, allowing 6in. between wheels at nearest point; the hind head is open and works with connection pivoted in centre. I have tried to ride this with different riders, but without success; cannot find out where fault is. I might add I never saw a real tandem, but made mine from what I could learn from Messrs. Rucker's list.—Bike.

[56361.]—**Telephone System.**—Will any reader inform me how to connect, in circuit, six telephones, each station having its own number of calls from one to six: whether a series or multiple system would be the best, and whether a line return would be preferable to earth?—Micro.

[56362.]—**Chemical Nature of Hemp.**—Can any one give us the chemical nature of hemp, and also of syole which is mixed with it for twine spinning? An article like that on The Chemical Nature of Cotton, p. 28, would be useful.—J. O. W.

[56363.]—**Pasteur's Vaccine for Splenic Fever.**—Do any of your readers know whether any experiments have been made with Pasteur's splenic-fever vaccine in this country; if so, by whom, and with what results?—Grouse.

[56364.]—**Wire Blinds.**—Will some one kindly help me in the following? I had some wire blinds to gild; but found that if the holes were not filled up the gilding looked very weak; filled holes up but could not get sharp edges. What is the best way to obtain same?—H. H.

[56365.]—**Flat Foot.**—I found, after much walking, the foot is apt to become flat, giving pain about the heel and causing me to be quite lame. As I am very fond of walking, this is a serious drawback to me. Could I get special boots made to brace up the foot? I wear stout lace boots (light shooting) carefully made to measure, but they do not support the arch of the foot sufficiently. Age 30. Weight 13st. 11lb. I ride a bicycle daily.—Pedestrian.

[56366.]—**Screwing Machine.**—I want to make a hand screwing machine to screw bolts up to ½in. Should feel obliged if any one would give an easy way of making one?—X. Y. Z.

[56367.]—**Cocoanut Oil**—What is the best means of purifying cocoanut oil, as supplied to soapmakers, so as to render it perfectly white, as supplied by chemists?—J. H. Thompson.

[56368.]—**Ventilator.**—Some time ago I saw a model of a ventilator suitable for halls and public places. The model was supported on a glass tube in which was a ball of cotton wool; on exposing the model to a current of air, the wool rose to the top of the tube, showing that a current of air was drawn up through the ventilator. This was accomplished by the peculiar position of a set of vanes in the ventilator (it was not on the Archimedian principle). A sketch, showing how the vanes are arranged to accomplish this, will much oblige.—C. L. Tweedale.

[56369.]—**Short v. Long Focus.**—Will some practical brother inform myself and others, what is the shortest focus a refractor should have, or may have, without suffering loss in definition or otherwise? I understand the power is greater with long focus; and the field, and of course light, is greater in short focus instruments. With some makers, the diameter of o.g. to the focal length, is as 1 to 12; while with others it is as 1 to 18; both these are extremes. Am I right in supposing a 5in. o.g., of 5ft. focal length, will give a field half as wide again as a 5in. o.g. with a focal length of 7ft. 6in. and, of course, using the same eyepiece or same power? "F.R.A.S." and others could give a very useful note on this point, showing the proportions, which would help many besides—Perciverance.

[56370.]—**Repairing Boilers.**—Will some one give me an idea how the boiler of Lord Charles Beresford's steamer was repaired, if, as stated, the round shot went through it when going to Sir Charles Wilson's rescue? Do the navy carry appliances made as suitable as possible for clapping on a hole such as would be made by a shot of any kind, and how would the patch be held against the pressure of the steam? I am sure it would be very instructive if an account were published, giving extent of fracture and method of repairing same in so short a time, and under the conditions the boiler was in.—J. Perry.

[56371.]—**Spoiled Negative.**—In printing from a dry-plate negative, I did not notice that it was not perfectly dry and the paper stuck to it, but came off easily when soaked in water, leaving a yellowish deposit on the gelatine. How can I get this deposit off as there are some figures on the plate which I do not wish to destroy?—Sepia.

[56372.]—**Flowerpots.**—Would S. Arlidge please to say how his moulds are made and how used, and of what material?—and oblige—M. W. S.

[56373.]—**Cane Window Screens — Ornamental.**—What is the process of making the above—the material, the mode of joining? Are patterns sold, if so, where?—Cazlab.

[56374.]—**Globe Telephone.**—Will some of "ours," acquainted with the construction of above instrument, kindly help me out of my difficulty? I have two of above, but cannot understand what the three wires leading out of the case are intended for. Will someone enlighten me?—Micro.

[56375.]—**Microscopical.**—I am anxious to stain and mount some sputum, so as to show the Bacillus tuberculosis. Will some kind friend who understands the process kindly assist me?—some medical friend, or perhaps Mr. Nelson may understand the process.—A. Bonnar.

[56376.]—**L. C. and D. R. Locos.**—Will some correspondent kindly give dimensions and weights of the new Bogie express locos. on above railway, as No. 861, also of the new tanks as No. 75?—L. B.

[56377.]—**Electrical.**—I have an electro-magnetic machine with double magnets. The bobbins are wound with wire about 24 cotton-covered; would the power be increased if I wound the bobbins with finer wire, and silk-covered? The power seems intermittent, and goes with far less power than it did at first.—Uninitiated.

[56378.]—**Draught of Launch Boiler.**—I have a steam launch, the boiler of which has no draught. I shall be glad if any of our practical friends will help me to remedy the defect. The boiler is horizontal return tubular, 3ft. 6in. diameter, by 4ft. 3in. long, with 30 2in. tubes; funnel 9in. diameter, by, 6ft. long; fire-bars, 2ft. 6in. long, by 1ft. 8in. broad; fire-brick bridge built at end of furnace. There is a steam jet into funnel, and also the exhaust pipe leads into funnel, but I cannot get steam to put the jet on; the smoke comes back through furnace door. I have sent my name and address for insertion in Address column, and shall be glad if any practical friend will communicate direct to me, when I can give any further particulars if required.—Wear.

[56379.]—**Bichromate Battery for Lighting.** I have one constructed as follows:—The lid is made of wood, into which are inserted ten zinc plates, and ten carbon plates; one carbon and one zinc are side by side, but the zinc of each pair is connected with the carbon of the next pair, and so on till the ninth is reached, the zinc of which is carried by wire to the lamp, and the carbon of the tenth to the other side of lamp. The lamp is a ten candle-power Swan incandescent one. The ten cells are of wood, pitched in and out, and the solution used 2½oz. bichromate of potash, 1oz. of sulphuric acid, to 1½ pints of water to each cell. All the connections are good, but the cells leak into each other. Can anyone tell me why I cannot obtain a light, and the remedy to make it right?—In the Dark.

[56380.]—**Colonel Drayson's "Glacial Epoch."**—I have been lately looking over the above work (1873 edition) and should like to ask our astronomical authority, "F.R.A.S." what mathematicians think of the author's position? If, as he states, the pole of the earth describes a circle, not round the pole of the Ecliptic but round a pole some 6deg. from it (29° 25′ 47″ N.P.D. 17h. 45m. R.A. in 1872), it appears to me that he makes out a very strong case. But that "if" is the difficulty, and I am not competent to solve the problem: hence my appeal to our kind friend.—Edward M. Richards.

[56381.]—**Legal.**—Forty years ago a mother made over to her daughter, by deed of gift, two houses "for her and her heirs for ever." Some time after, the mother being in want of money, effected a mortgage on the houses, the daughter giving consent and signing her name. Eventually the person who advanced the money called his money in, and that not being forthcoming, the houses were sold, the person who advanced the mortgage money buying at a sum not much in excess of what he had lent on them. The sons are now men, and have been told that the proceeding of the mother and daughter was decidedly illegal, and that the sons could claim the houses by taking the necessary proceedings against those concerned. The mother of the sons is alive, the grandmother is dead. The question is, Have the sons any reasonable chance of obtaining what they are assured is their own? If so, what is the best possible way for them to proceed in the affair?—Gwent.

[56382.]—**The Solar Eclipse in September.**—I purpose taking a trip to Wellington in September next to witness the total eclipse of the sun, and expect to be accompanied by two friends. I have a 3½ Wray refractor, my friends have reflectors 6 and 6½. I should be glad of any information to enable us to turn our observations to useful account. One of my friends purposes searching for intra-Mercurial planets, my intention is to try to photograph the corona. As my instrument is too small to use the principal focus, I purpose putting a shutter on the 60 eyepiece and attaching a chamber to receive the dry plate. I photographed the transit of Venus by a similar contrivance with a 3in. instrument, but the picture was not sufficiently sharp owing to neglecting to adjust for chemical focus. To make sure this time, I intend practising on sunspots beforehand. I shall use the ordinary ¼ plates sold at the photographic stores, but am in doubt whether the corona will require a longer exposure than the full sun. As there will be no time available for developing, I should be glad of any information on this subject from any of "ours" who may have tried a similar plan, so as to prevent disappointment.—John Grigg.

[56383.]—**The New Station at Birmingham.**—What are the dimensions of the New-street Station, Birmingham, and how do they compare with that at York? Is it true that the platform at Gloucester is 612 yards long?—Lever.

[56384.]—**G. W. R. Speed.**—Is it true that the G. W. R. 11.45 down train will be accelerated in June, and run to Bristol without stopping in two hours?—Lever.

[56385.]—**Victoria Dynamo.**—I am making a Victoria dynamo with eight field magnets, 2½in. by 1in., armature 6¼in. diameter; inside measurement of armature 3¼in. by ½in. thick. Would any reader of the "E.M." tell me what size wire to wind the armature and field magnets of the above machine with, what quantity I should require, also what light I should expect to get from such a machine?—A. W. H.

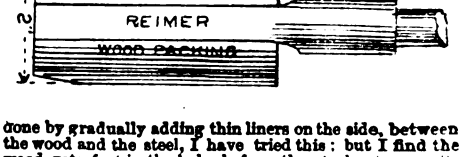
[56386.]—**Shuttles. — Compressed Teak.**—Can anyone inform me of what kind of boxwood shuttles are made? Is it Turkey box? What are the requisites in the wood? Is the teak to be compressed to give a weight, or what? Are not the shuttles shod with iron in the parts subject to friction? Any information on the subject of shuttles and the wood for them will be appreciated by me, as I have a son in foreign parts who might, if he knew the stuff required, be able to find a wood that will answer without compression.—Z. Y. X.

[56387.]—**Battery.**—I have a battery composed of four large zinc plates and sixteen carbon plates; the whole of them are fastened to a piece of wood, and all to be immersed in an earthenware jar. Which is the best and cheapest way to charge this battery, in order to produce a current of two hours' duration? I am, at present, using spirits of salts, but the action is too rapid on the zinc plates.—D. W. G.

[56388.]—**Motor.**—Will Mr. Bottone say how I can best trace the cause of my motor starting and giving off good power and then after a minute or two gradually coming to a standstill? There is no short circuit that I can find. When the battery current is divided between the armature and field magnet, the machine will hardly go at all (although the resistances are nearly equal) no matter what position the brushes are in. I have rewound both armature and magnet, but to no purpose. At present the machine has 16 on field magnet and 18 on armature, which is of Siemens form, 4in. long and 1½in. diameter.—Chingford.

[56389.]—**Incandescent Lamps.**—Given a lamp absorbing electrical power of, say, 50 volts, does it matter whether the power is obtained from large current and small force, or from large electromotive force but small current?—Ignoramus.

[56390.]—**Reamer.**—Inclosed is a sketch of a wood-packed reamer, the diameter of which is 2in. Will any of your readers kindly tell me how I can clean out a hole to 2¼in. diameter, with the same? I believe it can be done by gradually adding thin liners on the side, between the wood and the steel, I have tried this: but I find the wood gets fast in the hole before the steel gets near its work, owing to its being larger in diameter than the steel.—Beginner.



[56391.]—**Haydon's Cutter-Bar.**—Some short time ago I procured a Haydon's cutter-bar and a set of cutters for steel, iron, and brass; but having been previously only accustomed to the ordinary forged slide-rest tools, I do not seem to be able to turn out such good work with the cutter bar as I feel I ought to do, seeing that the Haydon cutter-bar has a very good name for general utility. Will someone please say if any special care or particular method is required in using them? Are they intended only for fine cuts? I am using them with a 4in. centre screw-cutting lathe, worked by the foot. What is about the greatest safe depth of cut they will stand on steel, wrought and cast iron, and brass—say on a bar 1in. in diameter? On account of the bend in the cutter-bar, the tool overhangs the top of the rest, much more than a forged slide-rest tool need do; is not this less rigid, and a drawback? It seems to me that without some special grinding apparatus to hold the tools when being repaired, it is difficult to maintain the side and plan angles of the cutters as they are sold, which, I presume, is essential to their doing good work. Will some other users of this cutter-bar kindly give me their experiences therewith? Of course I keep the point of the tool exactly level with lathe centres, so want of doing first class work is not due to any neglect on this score; I presume it is also correct, in turning straight cylindrical work between centres, to keep the shank of cutter-bar square with axis of mandrel?—BELLICOSE.

[56392.]—**Cubic Feet of Air per Minute.**—Supposing I have a pipe 12in. diameter, supplying air to a reverberatory furnace, by means of a mechanical blower. I should like to know how many cubic feet of air would enter the furnace per minute, when a water gauge shows a pressure of 3in. Please say also how the result is arrived at.—J. SMITH.

[56393.]—**Steam.**—If steam is issuing from a pipe 2½in. in diameter, and at a pressure on the boiler of 50lb. per square inch, what weight or volume of water would this steam represent per minute if it was condensed?—J. SMITH, Plumstead.

[56394.] — **Medical Battery.** — I have a medical continuous current battery, 40 ebonite cells, 1¼in. by 1¼in. by 3¼in., and get but a very slight current through it. I have recharged it with a strong solution of sal-ammoniac. Will one of "ours" please say if I have done right—if not, what should I use?—P. O. LINEMAN.

[56395.]—**Microscopical Staining.**—Will some reader kindly inform me how to use indigo carmine, i.e., sulphindigotate of soda, as a stain for vegetable tissues? —TYRO.

[56396.]—**Carbon in Cast Iron.**—We read that cast iron, when fused, has the property of dissolving an extra quantity of carbon, which is rejected on the iron cooling. Will any of our chemical readers kindly say what quantity of carbon is the iron able to take up in this manner, and in what manner is it to be done? I have an injector furnace by Fletcher, of Warrington. I melt the cast iron in it. Now, what I want to know is, in what manner am I to add the extra carbon so as to dissolve it in the iron, and what sort of carbon (graphite, lampblack, charcoal, &c.) should I use? I shall be thankful for any information on the subject. — EX-GARRISON GUNNER.

[56397.]—**Feeder for Organ Bellows.**—I have a small organ, and the feeders for the bellows act only one way. I want to make a feeder, 18in. wide, 4ft. 6in. long, to feed the bellows, with the up-and-down stroke; having enlarged the organ, I find the feeder too small, only working one way. Will any brother reader oblige? —LINOS.

[56398.]—**Boiling White.**—Can any reader tell me the way to tin brass work by boiling? I have tried boiling them in a solution of grain tin and cream of tartar in an iron saucepan? I have boiled for about six hours, but could get no deposit. Can any reader tell me where I am at fault?—A COUGHDROP.

[56399.]—**L. and N. W. Compounds.**—Can any one give dimensions of Mr. Webb's compound express engines, also some results in their working regularly?—G. D. SEATON.

[56400.]—**Harmonium.**—I am making a small harmonium, 3ft. long. I want one row of reeds, about 30 keys. Would some reader of the "E. M." kindly give me instructions how to make the reeds, where I can procure the brass, how I can tune them, and a few general instructions; and also where I can procure them already made, and what would be the cost of one set of reeds?—WORKING MAN.

[56401.]—**Faulty Induction Coil.**—I have an induction coil which seems to have broken down, giving only ½in. spark instead of 2in. Would steeping the secondary in hot paraffin (making tin cylinder to fit and placing over gas stove) until thoroughly soaked, restore the insulation, or would the process injure the ebonite tube and discs? The coil is disc wound.—FIFTEEN YEARS' SUB.

[56402.]—**Calculating Power Required.**—Will any reader favour me with a rule to calculate the power required to drive a machine, the first motion of which makes 400 revolutions per minute. With a lever attached, and 20lb. hung on it 20in. from the fulcrum, the machine begins to move?—M. E.

[56403.]—**Skrivanoff Battery.**—To "BOBADIL."—Many thanks for your answer to my query. Will you kindly answer the three following questions? 1st, Which chloride of mercury am I to use, the black or the red? 2nd, What salt should be formed after boiling, and is it necessary to boil for three hours? 3rd. What is the E.M.F. of the battery per cell?—ACCUMULATOR.

[56404.] — **Overflow in Water Waste Preventer.**—Lately new, supplied by Bodlings, of their own make. Various plumbers having been applied to, to remedy the waste, from time to time, without success, perhaps "our" Mr. Davies would kindly say how it is to be treated? At present it is a constant race between the West Middlesex Water Co., and the W. W. Preventer, the latter emptying the cistern as fast as the former fills it.—MONTMARTRE.

[56405.]—**Erecting Machinery.**—Would any of the readers of "Ours" tell me of a good book giving instructions upon erecting machinery, especially steam engines and rolling-mill machinery? I should be glad if some one would tell me the proper way to set about erecting a beam-engine with cylinder and motion in engine house, connecting rod and crank-shaft outside on a separate frame?—J. G., Bristol.

[56406.]—**Oleine Oil for Calico Prints.**—There is in the market, just now, a first-rate oleine oil for padding the prints before steaming. The goods padded with this oil, when steamed, produce a nice white; so it is certain there is something in this oil to make this change. I would like very well if someone would give me a hint on how to make it?—M. A.

# ANSWERS TO CORRESPONDENTS.

⁂ *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

## HINTS TO CORRESPONDENTS.

**1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.**

**⁂ Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.**

**The following are the initials, &c., of letters to hand up to Wednesday evening, April 15, and unacknowledged elsewhere:—**

T. J. ELMORE.—Pall Mall Electric Association.—Lord Rayleigh.—C. Rabache.—W. A. McClintock.—Hadfield's Steel Foundry Co.—C. Anthony, jun.—Robey.—Constant Reader.—Sefton Park.—W. Hardie.—Soho.—B. M.—Jno. M. Adams.—J. T. D.—Glatton.—J. R.—R. G.—T. H. L.—Arefes.—W. H. Elphick.—G. Fryer.—Bobadil.—Lt.-Col. Ross.—Silex Seadrift.

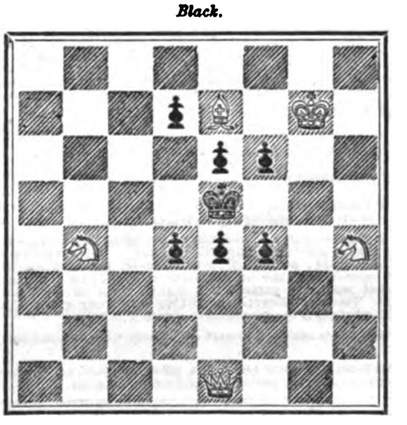
BUSY. (The easiest method is what is now known as the Hamiltonian system—that is, interlinear translations. It is advisable to learn the declensions and the forms of the verbs, especially the irregular ones. A study of such lessons as you can find in the "Popular Educator" would soon enable you to read books of the kind.)—AN AMATEUR. (See many replies in back volumes.)—INTERESTED AMATEUR. (We do not know of any books on the subject. To make incandescent lamps you will require some apparatus to compress the filaments and carbonise them, glass-blowing tackle, and a mercurial air-pump. If you really wish to enter upon their manufacture, you will find full particulars in back volumes.) —S. BEECHING. (No book specially devoted to the subject; but there is a good deal of information in Bourne's "Examples of Steam, Air, and Gas Engines," Longmans, price 70s.; also in his "Catechism of the Steam Engine," same publishers, which gives particulars of many patents. For a complete account of the patents you will have to search at the Patent Office, but you will get some in the volumes of the abridgments published relating to engines.)—F. BASLARD. (So-called self-acting fountains have been described many times; see pp. 402, 425, Vol. XXXIX., pp. 112, 247, 260, Vol. XXXVIII., and Nos. 459, 582, 801.)—AMERICAN LEATHER. (They are preparations of linseed-oil with driers and pigments, sometimes with the addition of gum copal, &c. The "patent" is stoved. See the indices. Thanks for the other matter, but you will find something about it in No. 1002, as well as in back volumes.)—LEVER. (First query not of sufficient interest. You should procure the specifications if they are patented. 2. The term means that a burner consuming five cubic feet of gas per hour gives a light equal to so many standard sperm candles. A standard candle is one that consumes 120 grains of sperm per hour. 3. For such questions you should refer to a cyclopædia. Meerschaum is a silicate of magnesia, obtained principally from Asia Minor, where it is found in veins or nodules amongst the serpentine rocks. Steatite is also a silicate of magnesia, a massive variety of talc commonly known by the name French chalk. Asbestos, too, is a silicate of magnesia, the name being applied properly to the peculiar fibrous variety of amphibole.)—GEO. HAILEY. (Perhaps you will say what new battery salt it is that you mean? If it is some trade article, the question is scarcely likely to meet with an answer.)—W. H. (Your query about musical box has been answered so recently as replies No. 55691. See p. 544, No. 1039.)—W. TWIGG. (It is a modification of one of Prof. S. P. Thompson's patented devices. See p. 144, No. 943. We do not know who sells parts.)—ONE IN A FIX. (Not of sufficient interest. Models of the kind are not worth making; but you can stiffen the cardboard by sizing and varnishing it.) -T. BAKER. (Mix the desired pigment with gum water. Alphabets can be obtained from the dealers in artists' materials, but scarcely books of designs.)—J. W., Cleackheaton. (Use finer and still finer emery, and finally polish with crocus. 2. An artificial seawater is made by dissolving in a gallon of filtered rainwater or boiled water 3½oz. of common salt, ¼oz. of Epsom salts, 200 grains of chloride of magnesium, and 40 grains of chloride of potassium. Put some fresh seaweed in for some time before using. 3. The camera obscura is described in such books as Ganot's "Physics"; but you will find any details about that and the other question in back volumes.)—WOLSEY. (See answer to F. Baslard.)—VOX. (Yes, certainly, or zinc, compo, or tin. You must apply to the company for prices of telephones.)—AN ENGINE FITTER. (See indices; but better spend the money in consulting a medical man.)—W. D. GEORGE. (Use a little cream as the kid reviver. For thought-reading, see the indices of Vols. XXXVII., XXXVIII.; as to the rings, some are split, so that the others can be readily passed into them; but only the solid rings are shown to the audience.)—STAR. (We believe Mr. Eassie, Argyll-street, W., can give particulars of the Cremation Society.)—WORCESTER. (Look through recent numbers; also at p. 133, last week.)—T. B., Rochdale. (Recipes for "lime-juice and glycerine" in Vol. XV. pp. 157, 261. The commonest samples are made of lime-water and oil, with just a little glycerine. A good recipe is olive oil 20oz., lime-water 20oz., glycerine 2oz., essence of lemon 100 drops. If such a mixture is to be put on to the hair, it would be advisable to add a quarter of an ounce of cantharides. That should be added to the oil before mixing. After standing for a day on the cantharides, filter the oil through paper and mix with the lime-water.)—T. B. (The "five-barred gate" in No. 921; the four-barred in No. 924.) —MODEL ENGINEER. (See the indices.)—W. H. T. (If you will say what we are to understand by an "electric engine," we may be able to help you; but you might help yourself by looking to see if there is not something suitable in back volumes.)—ONE IN A FIX, Priestfield. (You had better copy the remaining reeds, or else procure new plates, which you can obtain of any dealer in musical instruments. Steel is better than brass for such instruments; but it is difficult to work. As your plates are not brass, we presume they are zinc.)—A HOBBLING SUFFERER. (If you are not satisfied with the verdict of two medical men, why not go to a hospital, and ascertain what the surgeons think of it? If you feel nothing of it for months together, it is certain it is not a bone out; but how anyone can help you without examining the part we fail to understand.)—W. CHAPMAN. (The question is of no interest, and you have no legal position. You voluntarily accepted the terms, and so far your "loss" is only hypothetical.)—RUSTIC. (The insertion of such a query would produce a variety of replies, simply because it is not definite. Some readers would imagine you wanted a carbon paper, whereas, if we understand you, the process is one of those in which paper with minute perforations is employed. That is tough tracing-paper, which you can make by dressing "bank post" with Canada balsam dissolved in turpentine. See back volumes for other recipes, or p. 88.)—J. J. S. C. (Formulæ for preparing emulsions, both gelatine and collodion, in back volumes.) — FERROTYPER. (Use an ordinary good "white hard" varnish, thinned with pure methylated alcohol. There are several recipes on p. 418, No. 954, and elsewhere in back volumes.)—G. ALLSOPP. (You want a little roller press, which you can obtain of any dealer in photo. materials. For enamelling, see p. 116. No. 915.)—TONSOR. (The cause is constitutional. See the indices. 2. Would it not be simpler to remagnetise the needle? Is it true that it is weighted to keep it in position?)—ONE IN A FIX. (A little fire kept in at night will not do, because you will be heating the conservatory when the air is mild, and allowing it to cool down at night when the frost is outside. Better have no heat at all than that. You must devise some independent heating apparatus.)—ROB. CAUS. (We *do*, of course; but we require more in such cases than we fancy you can give us, and we fear our space would hardly admit of such a series as you propose.)—E. F. J. H. (We know nothing of the school referred to; but it is not necessary to enter there or anywhere else, or to pass any examination, to style yourself a civil engineer.)—IMPRIMATUR. (Pray who is the American "scientist," and what is a "veridical" phantom, and which part of his own body does he evolve his phantom double from? All humbug!)—ANXIOUS. (No one but a medical man who had seen it can say. If he is of opinion that it must be cut out, submit, and be thankful if a cure is effected. If you delay, the doctor will presently have to tell you it is too late to undertake the operation.)—VLADIMIR. (It is utterly impossible to follow your copy as it is arranged. It is bad enough when any MS. is on both sides of the paper; but when it consists mainly of mathematical formulæ, and the sequence of the pages arranged in the fanciful manner you have adopted, confusion becomes worse confounded.)

# CHESS.

ALL Communications for this department must be addressed to J. PIERCE, Llandwrog, Carnarvon.

PROBLEM DCCCCXXXV.—"RESPICE FINEM."

*Black.*



*White.* [5+7

White to play and mate in two moves.

SOLUTION TO 933.

| *White.* | *Black.* |
|---|---|
| 1. Q to Kt 8 | 1. Anything |
| 2. Kt or Q mates | |

(Five variations.)

## NOTICES TO CORRESPONDENTS.

CORRECT SOLUTIONS to 933 by R. A. Bennett, Rev. W. Anderson (Old Romney), W. T. Bayne, F. O'N. H., A S. Olver, A. A. E. Lecluse, Raymond. F. A. Vincent, E. Stanley Follwell (main variations must be published; names of competitors have been given). Exon (neat, no waste of force, second solution cleverly avoided), Streetgate, P. S. Pochin, and J. E. Piper.

To 923, by R. A. Bennett, W. T. Bayne, R. Fison, and R. C. J.

Tourney Problems from "Phono," and "Aut Vincere aut Mori"; also amended problem from "Measure for Measure." Game from T. Bourn.

Ariadne.—Correction made in solution.

L. L. Chivers.—If in 932, R takes R, 1. B-Kt 4 is an effectual reply.

A. O. E. Lecluse.—Name entered.

H. A. Harborrow.—The solution as printed to 931, is quite correct: if 3. P takes Kt, 4. P mates, if 3. anything else, Kt mates. You have overlooked in your solution, that after 2. R-K R 6, 2. P-K 7, 3. R takes P, Black has no move! Your solution to 933, is also incorrect for 2. Kt-Q 7, is not mate, as K can move to Q 3.

Exon.—1. It includes three move-problems as well. 2. There is no entrance fee necessary. 3. About seven months. 4. First prize £1 1s., second, Tomlinson's "Amusements in Chess" (out of print); third, Collins' "Problems"; fourth, Mills's "Problems and Poems"; fifth, Beechey's "Chess Blossoms."

Bethnal Green.—Solution to 931, correct, but not author's; that to 932 is wrong, as if 1. K B moves, 2. K does not discover mate, since B-K can take R.

**Every Workman connected with the Building Trades** requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence, at 332, Strand, London, W.C.

"THE BUILDING NEWS" is the Principal Journal representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is On Shilling for Twenty-four Words, and Sixpence for every Eight Words after

## TERMS OF SUBSCRIPTION.

### PAYABLE IN ADVANCE.

6s. 6d. for Six Months and 11s. for Twelve Months, Post-free to any part of the United Kingdom. For the United States, 13s., or 3 dols. 26c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 6d. each to cover extra postage.

Messrs. James W. Queen and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 26c. gold, or Thirteen Shillings per annum, post-free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 6d. each copy, to cover extra postage.

Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX. bound in cloth, 7s. each. Post free, 7s. 9d.
Vol. XL. now ready, price 7s. Post free 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post-free from the office (except index numbers, which are 3d. each, or post-free 3½d.)

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XI. and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

## CHARGES FOR ADVERTISING.

| | s. | d. |
|---|---|---|
| Thirty Words | 2 | 6 |
| Every additional eight words | 0 | 6 |

Front Page Advertisements Five Shillings for the first 40 words afterwards 9d. per line. Paragraph Advertisements One Shilling per line. No front page or paragraph advertisement inserted for less than Five Shillings. Reduced terms for series of more than 6 insertions may be ascertained on application to the Publisher.

ADVERTISEMENTS in EXCHANGE COLUMN—for

| | s. | d. |
|---|---|---|
| Twenty-four words | 0 | 3 |
| For every succeeding Eight words | 0 | 3 |

ADVERTISEMENTS in the SIXPENNY SALE COLUMN.

| | s. | d. |
|---|---|---|
| Sixteen words | 0 | 6 |
| For every succeeding Eight Words | 0 | 6 |

*** It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions; and in cases where the amount sent exceeds One Shilling, the publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O's.

The address is included as part of the advertisement, and charged for.

Advertisements must reach the office by 1 p.m. on Wednesday to insure insertion in the following Friday's number.

**Epps's Cocoa.**—Grateful and Comforting:—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—*Civil Service Gazette*.—Made simply with boiling water or milk, Sold only in packets, labelled—"JAMES EPPS and CO., Homœopathic Chemists London."—Also makers of Epps's Chocolate Essence

HEARTHRUGS.—The *Catholic Times* says:—"We have this week inspected the Hearthrugs advertised by Nelsey and Co., of Stockport, and can guarantee them to be everything that the firm represent them in their advertisements. They are really cheap and beautiful articles, and we feel sure that our readers will not be disappointed if they intrust their orders to Messrs. Nelsey and Co., and as the goods come direct from the manufacturers, they are enabled to sell them at prices within the reach of all classes."—For advertisement see page VII of this paper.

## NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a Pink Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

**Holloway's Pills and Ointment.**—Holloway's Pills purge the Blood of the foul humours engendered by unhealthy atmospheres and dangerous occupations. They arrest inflammation, and correct all disorders of the liver, stomach, and bowels. Holloway's Ointment cleanses and heals ulcers, wounds, and abscesses, and allays the pain of Rheumatism and Neuralgia.

## OUR EXCHANGE COLUMN.

*The charge for Exchange Notices is 3d. for the first 24 words and 3d. for every succeeding 8 words.*

**Good Value Offered** (cash or instruments) for all kinds of sound or repairable Scientific Appliances.—Caplatzi, Science Depot, Chenies-street, near British Museum. Established 1862.

Wanted, a good Collection of **Stamps**, also coins and Bric a Brac of every description, good exchange, approval required.—Address, Edward W. Drury, Hull.

**Perambulator Wheels**, with turned axles, ¾ best Rubbers, 54 Wires, Brass Caps, complete, on approval, with pleasure. Exchange offers.—310, Bilston-road, Wolverhampton.

**Lathe Wheel**, 28in., 5 speed, 50in. crank, turned, bored, treadle, complete, lathe standards, 7½ lathe head; 100 "E. M." Exchange.—Smith, Bilston-road, Wolverhampton.

"**English Mechanic**, from commencement, 40 Vols., 19 bound, all in perfect order. No reasonable offer refused, owner going abroad. Will exchange for central-fire gun.—Major Allen, Gosport, Hants.

**Cutter Yacht**, with all necessary sails, ropes, spars, and blocks; built by master shipbuilder; copper fastened. Will exchange for Bicycle or Model Engine, value £4.—A. F. Whisley, Bank House, Brightlingsea.

Will exchange capital Bow **Drill Stock** and ten fitted drills for double-jointed Pencil Compass, Needle Points, or offers.—J. Muir, 9, Church-street, Dumbarton.

No. 3 Breechloading **Pistol**, octagon rifled barrel, cost 30s., and 100 cartridges. What offers of recent volumes English Mechanic.—A. Perks, 18, High-street, Warwick.

"**Balfour's Botany**," nearly new; "Grindon's British Plants"; 26 Nos. "Brook's Botany," incomplete, lot cost 28s. Wanted, ¼ or ½ wide-angle Lens.—C. Roxhead, 606, Dalmarnock-road, Glasgow.

Free on rail. Stamp for reply.—H. Jones and Co., Viaduct-street, London, E., near Bethnal-green Junction, G. E. Ry.

Circular **Stocks and Dies** for cutting full threads at once running down. A great improvement on the old style. See testimonials. Lists, one stamp.—Jermy and Son.

**Testimonial.**—"Gentlemen,—I am very satisfied with the screw-tackle. It is certainly a novelty. It is particularly well suited for Amateur Mechanics and small Manufacturers." For full copy of this and other testimonials send for lists.—Jermy and Son, North-street, Stafford.

Astronomical **Telescope** for sale, with Wray's first quality o.g., 3½ clear aperture, together with five sliding eyepieces and sundial, complete, with tall tripod stand, brass pillar, and steadying rod. Also equatorial head in iron and brass, with levelling screws, and tangent screw in R.A., suitable for screwing to iron pillar.—B., 264, Oldham-road, Royton, Lanc.

**Billiards.**—Great success of Thorpe's Patent Automatic Cue Tips. Cannot fly off. Cues retipped instantly.

**Billiards.**—Excellent testimonials from Roberts, jun., champion, and other professionals. £5 per week easily earned.

**Billiards.**—District Agents wanted. Send 9 stamps for particulars and sample cue end fitted with patent.

**Billiards.**—Five Shillings for sample cue, also fitted, and 3 extra tips. Thousands already in use.

**Billiards.**—Apply to sole representative for United Kingdom.—A. W. Morgan, Lancaster Avenue, Fennel-street, Manchester.

Eight **Change Wheels**, 85 to 120, bored to one inch, 5 16th pitch, cheap.—T. Taylor, Willingdon, Sussex.

**Tricycle**, "Zephyr," Coventry make, new, perfect repair, only, £10.—H. P., East Howle, Ferry-hill.

**Dollond Achromatic**, 3 inch, new, with three eyepieces, in case, with strong stand, price £10.

**Screw-cutting Lathe**, 3 inch centres, slide-rest, change wheels, nearly new, perfect order, price £10.—H. P., East Howle, Ferryhill.

**Microscope**, by Watson, new, Bulloch's swinging substage, mahogany case, eyepieces, iris diaphragm, complete, £10.

**Incandescent Lamps.**—Some Woodhouse and Rawson, 50 volt, never used, 3s. 6d. each, best filament.—Sledge, Wyatt, and Co., Electrical Engineers, 95, Wirtemburg-street, Clapham.

New 4in. screw-cutting **Lathe**, superior finish, complete, 10 guineas.—A. Halls, Howard-street, Yarmouth.

Large quantity of **Turning and other Tools**, for iron and wood, must be disposed of. List sent.—Offers Photo. Apparatus.—J. Bate, 60, Bridge-street, Golborne, Newton-le-Willows, Lancashire.

**Steam Canoe**, new, seat 3, with machinery complete, £30. Photo, 4 stamps.—Chennall, Eastville, Bristol.

"**English Mechanic**," Vols. XXII. to XL., clean and unbound, 40s.—W. M., 62, St. Stephen's-street, Salford.

**Microscopic.**—Good miscellaneous Slides for disposal, only 2s. 8d. dozen, post free.—Mathieson, 42, McKinlay-street, Glasgow.

**Coca Leaves.**—A splendid consignment of this grand and safe stimulant just received. All will benefit by it.

**Coca Leaves.**—Sample packet, including medical and scientific opinions, post free, 13 stamps.—Marks and Co., 17, Newcastle-street, Farringdon-street, E.C.

Engineer's **Stocks and Dies**, Whitworth pitch, superior quality, and very cheap. Lists, 1 stamp.—Jeremy and Son.

**Engineer's Taps**, ¼in., 1s. 1d. ; 5-16in., 1s. 2d. ; ⅜in., 1s. 3d. ; 7-16in., 1s. 4d. ; ½in., 1s. 6d. ; ⅝in., 2s. ; ¾in., 2s. 6d. ; ⅞in., 3s. ; 1in., 3s. 6d.—Jeremy and Son, North-street, Stafford.

Good 6in. **Slide-Rest**, had very little wear, price 30s.—A. H., 5, Wymering-terrace, Lavender Hill, S.W.

First-class model **Hull of Boat**, 2ft. long, price 9s.—A. H., 5, Wymering-terrace, Lavender-hill, S.W.

**Advice** upon any Electric Bell difficulties by return of post. Terms, 1s.—Wragge, Electrician, Chester-le-Street, Durham.

**Dynamo Machine**, second-hand, 50 twenty-candle Lamps, cost £75. Price £40.

**Dynamo Machine**, second-hand, 30 twenty-candle Lamps, cost £50 ; take £26 ; splendid condition.—W. Banks.

One H.-P. **Otto Gas Engine**, nearly new, cost, with fittings, £110. Price £90.—W. Banks.

**Wimshurst Machines**, 17in. plate, half-gallon Leyden Jars, best make, 7in. spark, 70s.—W. Banks.

Small **Dynamo** to light six ten-candle lamps, with stand and driving arrangement, £5 10s.—W. Banks.

Ebonite (Bell pattern) **Telephone Cases**, screw caps, best quality, 7s. 6d. pair, post free.—W. Banks.

Banks' **Instantaneous Shutter** is the best yet produced. Made entirely of metal ; strong and light.—W. Banks.

Banks' **Instantaneous Shutter** for a half-plate Lens can be carried in the waistcoat pocket.

Banks' **Instantaneous Shutter**, from its peculiar construction, is the quickest extant.—W. Banks.

**Banks' Shutter** is cheap. 2in., 10s. 6d. ; over 2in., 15s. Send for list.—32, Corporation-street, Bolton.

**Jigger Sawing Machine**, separate counter-shaft, new, £12. Photo, 6d.—2, Etruria-street, New-road, Battersea.

**Universal Trade and Amateur Supply.**—Lecture requisites ; light, heat, air, water, geology, engineering, chemistry, photography, &c. Wholesale and export.—Caplatzi.

Noted for cheap **Lecture Apparatus** of all kinds. Astronomical, Surveying, Chemical. Models, Lathes, Photography, Medical Electricity.

**Electrical and Magnetic Departments** replete with thousands of different articles ; specially low prices for good Bell, Telegraphic, Lighting Appliances.

New Catalogue, 2d. **Caplatzi**, Science Depot, Hire and Exchange, Chenies-street, Tottenham-court-road. Established 1862.

**Mesmerism.**—Instructions showing how anyone can become first-class mesmerists. Success certain. 8 stamps.—Below.

**Thought-Reading.** — Instructions showing how anyone can become Thought-Readers. 8d.—Below.

**Ventriloquism**.—Instructions showing how anyone can acquire this wonderful art, 6d. Never fails.—Below.

**Clairvoyance**, or "Second Sight" (instructions in). Success guaranteed. 8d. All 4, post free, 14d.—G. Marquis, Allhallowgate, Ripon.

"**English Mechanic.**"—Any back number, 3d. each. Indixes, 6d. Volumes, 2s. 6d.—Sladen, 33, Cank-street, Leicester.

Good **Cast Steel**, ⅜ dia., 3ft. lengths, 12s. per cwt.—Gilbert, Oxford-road, Sheffield.

Twenty assorted **Fretwork Patterns**, full size, price 7d. Six dozen Fret Saws, 1s. 3d.—C. W. Bickle, Stoke, Devonport.

**The Kinetic Engineering Company**, 36 and 37, Brooke-street, Holborn, London. Circulars and list post free.

**Dynamo Wire**, 1s. 2d. per lb. Line Wire, 29s. 6d. per mile. Pushes, 4s. per dozen.—Kinetic Company.

**Leclanche Cells**, best. No. 1, 16s. ; No. 2, 19s. ; No. 3, 22s. 6d. per dozen.—Kinetic Company.

**Electric Bells.**—Best quality, workmanship, appearance and value in market, 40s. per dozen.—Kinetic Engineering Company.

**Maiche Patent Battery.**—Best yet produced. Circulars and Scientific Reports post free.—Kinetic Engineering Company.

**Electrical Supplies.** Wholesale only.—Kinetic Engineering Company, 36 and 37, Brooke-street, Holborn, London, E.C.

Shunt wound **Dynamo** and Serrin Arc Lamp, cost over £40. Will take £25 or good exchange.—John Grime, Hull.

Fletcher's **Foot Blower**, cost 35s., quite new ; also large Blow Pipe and Hearth. Will take £2 10s., or offers.—J. Grime, Hull.

**Photographs** of G. N. Ry. new side tank, No. 696, size, 8 by 5, free 1s. 1d. List.—F. Moore, 1, Nass-road, Wood-green.

Two 10 candle-power **Lamps**, 2s. 6d. each, cost 5s. Books cheap.—E. Ross, Regent House, Sydenham.

**Stocks and Dies**, Anvils, Vices, Bicycles, Tricycles, Bellows, &c. Prices free. Repairs.—33, Porthope-road, Birmingham.

For sale, double-action oscillating **Steam Engine**, bore of cylinder, ⅜in. ; stroke, 5-16in. ; diameter of flywheel, 3in. ; thorough working order, price £2.—Mr. Byrd, Albion-place, Marlborough, Wilts.

**Opera Glasses**, 4 lenses, metal parts, covering all complete, with instruction for fitting, 1s. 3d. free.—Theobald.

**Electric Motor.**—Castings, Wire, Core, Reel, &c., and instructions, 1s. 3d. free.—Theobald, 11, South-street, Greenwich.

**Astatic Galvanometer**, glass shade and levelling screws, 12s. 6d.—G. Bowron, 97, Crawford-street, Marylebone, W.

**Planing Machine**, 6ft. by 2ft., £40 ; 10in. gap slide lathe screw cutting, 16ft. bed, £45, or offers.—J. Deighton, 15, Nelson-street, York.

Three H.-P. Vertical **Engine**, £4 ; Gas Engine, 2 H.P., £17, ½ H. P., £35 ; set of ball bearings, finished, 30s.—J. Deighton, 15, Nelson-street, York.

**Steam Gauges**, Spring Balances, Indicator Counter, Water Gauges, wheel valves. Cheap for cash.—J. Deighton, 15, Nelson-street, York.

**Battery**, bichromate, highest electrical efficiency, Contains 10 per cent. more chromic acid than potash bichromate. Lee's new double Bichrome. Soluble in own weight water. No crystals formed. Recommended in "E.M." No. 1044 (Reply 55916). 7d. 1lb., 7lb. sample parcels. 6½d. lb. in 56lb. lots.—R. A. Lee.

**Wire**, double cotton-covered, No. 8 to 18, highest conductivity. 2s. per parcels post, 1lb., free. Ditto, 18 to 22, 2s. 3d.—R. A. Lee.

**To Amateur Boat Builders and Others.**—15ft. by 3ft. by 18in. deep Launch, Working Plan, 5s. Paper Templates of Frames, 10s. Wood Model, 5s.—A. Dorrington, West Gorton, Manchester.

The Amateur and Dentist's **Gas Engine**. Castings, 47s. Drawing, 5s. Litho, 3 stamps.—A. Dorrington, West Gorton, Manchester.

Launch **Gas Engine**. Litho and particulars, 3 stamps.—A. Dorrington, West Gorton, Manchester.

Half horse-power Horizontal **Engine Castings**, ports in cylinders, 12s. 6d. Drawing, 18 stamps. Litho, 2 stamps.—A. Dorrington, West Gorton, Manchester.

Model Compound Condensing Marine **Screw Engine**. Castings, 18s. Litho, 4 stamps.—A. Dorrington, West Gorton, Manchester.

**Drilling Machine**, self-acting feed motion. Castings, 7s. 6d. Forgings, 5s. Drawing, 18 stamps.—A. Dorrington, West Gorton, Manchester.

**Stationary Engines**, Launch Engines, and Model Engine Castings. List, 1 stamp.—A. Dorrington, West Gorton, Manchester.

## Wanted.

Old Microscopes, by Adams, Amici, Baker, Dollond B. Martin, Pritchard (Goring's "Engiscope"), Varley, and other old makers.—J. Mayall, Junior, 224, Regent-street, London, W.

Birmingham Goods.—Jewellery, Watches, Clocks, Hardware, Harmoniums, Furniture. Agents wanted. Wholesale catalogues, 500 Illustrations free.—Henry May, Merchant, Birmingham.

Agents Wanted on commission to sell a new Invention to users of steam power.—Apply Salford Injector and Ejector Co., Salford.

Agents Wanted.—Morgan's celebrated Improved Scale Preventing Compound. Nothing better or cheaper.—W. H. Morgan, Engineer, Gloucester.

Wanted, first-class second-hand 5in. or 6in. Amateur's Lathe, screw-cutting preferred, with plain attachments. Must be in perfect order and accurate. Also back volumes of English Mechanic, "Forge and Lathe," and "Design and Work."—P. S. Macgowan, Box 1663, Boston, Mass.

Wanted, Vols. I.—IV. English Mechanic, unbound preferred.—H. H., 8 St. Mark's-road, Wolverhampton.

Wanted, Catalogues to assist in purchasing Gas Engines, Lathes, Lanterns, Electrical, Optical, and other instruments, also scientific toys to complete present workroom and family amusement.—C. N. Gilbert, Architect, 80, Sturt-street, Ballarat, Victoria.

Deer Horns Wanted.—M. Day, Hook and Handle Manufacturer, 56, Driffield-road, Old Ford, London.

Wanted, cheap work, "Differential and Integral Calculus," or one on each.—T. C., Home Lodge Avenue, Surbiton.

Lathe wanted, 4in. screw-cutting, second-hand, complete, foot power.—Thos. Ford, 66, Rosamond-street east, Manchester.

Wanted, "Airy's Gravitation," and recent works on Natural Philosophy.—F. Medd, 68, Princes-street, Southport.

Carbonado wanted.—Dealers in quote price and particulars to W. A. C. Smith, 142, Ingleby Drive, Dennistown, Glasgow.

Wanted, Launch Engine, about 5in. by 5in., with reversing gear. Condition immaterial.—Ellis, 2, Princes-street, Doncaster.

Wanted, a large Bell, second-hand, for factory, weight, about 1½ cwt.—Apply, low figure as possible, to Albert Steam Works, Newbury.

Wanted, small Blast Bellows, in good condition. State lowest price. Also furnace bellows.—119, High road, N.W.

Agents Wanted everywhere for Rubber Stamps. Complete Outfit, 2s. 9d., free.—William Shepard, 45, Oxford-street, Derby.

Wanted, Boiler, about 1½ H.-P., in good condition.—Price and full particulars, S. Dobson, Hamlet-road, Chelmsford.

Wanted, a small-sized Water Motor, Bailey's Thirlmere preferred.—State price to Watts, Settle, Yorkshire.

Books on Engineering or Scientific Subjects wanted for cash.—Particulars to J., 759, Old Kent-road.

## Addresses.

"Wear."—W. S. Dawson, 8, Cambridge-terrace, Sunderlane.

## Educational.

Howard's Orthographic Shorthand. Words properly spelled. Lessons by post, 1s. each.—247, Ellor-street, Pendleton, Manchester.

THE SHEET METAL WORKER'S
INSTRUCTOR.
By R. H. WARN, Practical Tin-plate Worker.

Containing Practical and Simple Rules for striking the various patterns required for Sheet Iron, Zinc, Copper, and Tin-plate Workers.

Illustrated by 32 Plates and Diagrams.

The work has been examined, practically tested, and received a special note of recommendation from the Gas Meter Makers, Zinc Workers, and Tin-plate Workers.

Published and sold by the Author only.
NOTE CHANGE OF ADDRESS—
94, ST. AUGUSTINE'S ROAD, CAMDEN SQUARE, N.W.
Price, handsomely bound in cloth, 10s. ; post free, 10s. 6d.
P.O.O. made payable Post Office, Camden-road.

---

ENORMOUS SALE
OF
HEARTHRUGS.
DIRECT FROM THE MANUFACTURERS.

S. NELSEY & CO., the well-known Stockport Firm have now to hand 20,000 DOZEN of their world-famed HEARTHRUGS, which have gained an unprecedented demand owing to their cheapness and beauty and as they are direct from the factory, the newest patterns and latest colours may be relied upon. They are 6ft. long by 3ft. wide. Each rug is handsomely blended in six or seven of the richest colours, and may be had in shades to match any colour of carpet or suite. The designs are exquisite, viz., Grapes, Ferns, Flowers, Oak Leaves, Masonry, Cats and Kittens, &c., &c., &c. They are suitable for drawing-room, dining-room, bed-room, or kitchen. We receive constant renewed orders and Testimonials from all parts. Since the establishment of the Parcels Post, no place can be too distant for us to send to. The testimony of rich and poor alike is, "Never before was such a large and handsome Rug offered at the price."

In order that every home in the land may possess one or more of these beautiful Rugs, we will send them (carriage paid) at the prices stated in Coupon below.

ENGLISH MECHANIC COUPON.
Name.......................................................
Address.......................................................
We guarantee to send one Rug as advertised above on receipt of P.O.O. for 3s. 6d. ; two or 6s. 3d., three for 8s. 9d. six for 16s. 6d. twelve for £1 12s. If stamps 1d. extra with each order.
(Signed) S. NELSEY & CO.

All P.O.O.'s to be made payable at Heaton-lane post office to
S. NELSEY & CO.,
7, Commercial Buildings, Heaton Lane,
Stockport.

---

ENORMOUS SALE OF GOVERNMENT
HEARTHRUGS.
SIX FEET LONG—THREE FEET WIDE.
50,000 Doz. offered to readers of this Paper at 2s. each.
Every Purchaser Delighted, Selling in Thousands Weekly.
HUNDREDS OF TESTIMONIALS.

J. WATTS, 113, Brunswick-road, Liverpool, is offering 50,000 doz. GOVERNMENT HEARTHRUGS, which have gained a world-wide reputation for Cheapness and Beauty. These Rugs are SIX FEET LONG and THREE FEET WIDE—seventy-two inches by thirty-six. Each Rug is handsomely blended in six or seven different colours. The designs are exquisite, including Ferns, Oak Leaves, Flowers, Masonry, &c. They are suitable for Drawing-room, Bedroom, Dining-room, Parlour, or Kitchen, 2s. each. In order that every Householder in the land may possess one of these Beautiful Rugs, I will send at the price stated.

FOR A LIMITED TIME ONLY.

E. M. GOVERNMENT RUG COUPON. 17.4.85.
On receipt of this Coupon and P.O.O. value 2s., or 26 stamps, I guarantee to send one Government Hearthrug, SIX FEET LONG, THREE FEET WIDE, as advertised.
(Signed) J. WATTS.

Post Office Orders to be made payable to Low-hill Branch to
J. WATTS, 113, BRUNSWICK ROAD, LIVERPOOL.

---

TO AMATEUR TURNERS AND THE TRADE.

AFRICAN BLACKWOOD, BOXWOOD, BARWOOD, COCUSWOOD, EBONY, LIGNUM VITÆ, LANCEWOOD, MYALL WOOD, OLIVE WOOD, PURPLEWOOD, ROSEWOOD, SATINWOOD, SNAKEWOOD, TULIPWOOD, ZIRICOTI, MADAGASCAR RED WOOD, KINGWOOD, and many other Fancy Woods.

GEO. POTTIER,
Foreign Hard Wood and Fancy Wood Merchant,
115, Bethnal Green Road, London E.
Colleges and Schools Supplied. List of Woods, one stamp.

---

ONE BOX OF CLARKE'S B 41 PILLS is warranted to cure all discharges from the Urinary Organs, in either sex (acquired or constitutional), Gravel, and Pains in the Back. Guaranteed free from Mercury. Sold in boxes, 4s. 6d. each, by all Chemists and Patent Medicine Vendors throughout the world ; or sent to any address for sixty stamps by the Makers, THE LINCOLN and MIDLAND COUNTIES DRUG COMPANY, Lincoln. Wholesale Agents, BARCLAY & SONS, London, and all the Wholesale Houses.

---

G. BIRCH AND CO., BLOOM STREET TOOL WORKS, SALFORD, MANCHESTER.
Manufacturers of High-class Amateur Tools, Self-acting Slide and Screw-cutting Lathes, Drilling, Shaping, Milling, and Planing Machines. SPECIAL Amateur Milling Machine on independent stand, with treadle motion, complete.

MEDALLION TURNING LATHES of New and Improved Design. Chucks and Ornamental Turning Apparatus of every description. WHEEL CUTTING, Circular and Straight Line Dividing and Drilling. ENGRAVERS' RULING and ROUTING MACHINES, &c. Amateurs supplied with Materials; Castings in Cast or Malleable Iron, Phosphor Bronze, Gunmetal, and Steel. Hard Woods kept in stock.

*Sole Authorised Makers of Amateurs' Tools Invented by Mr. Jesse Lee*

---

25, CATHERINE-STREET, STRAND.—Spacious extensive PREMISES, suitable for offices, publishing warehouse, or any commercial purpose, TO LET. Capital position and in good condition. Rent £350 per annum. On 7, 14, or 21 years lease.—Apply to E. J. KIBBLEWHITE, 332, Strand, London, W.C.

---

£20 TOBACCONISTS COMMENCING.—An Illustrated Guide (116 Pages), HOW TO COMMENCE BUSINESS RESPECTABLY, 3 stamps.—H. MYERS and CO., Cigar and Tobacco Merchants, 109, Euston-road, London. Wholesale and Export Only. Telephone No. 7541

---

HARMONIUM and AMERICAN ORGAN FITTINGS of every description. Esteves, best quality 14s. 6d. per set. Turban and Co.'s celebrated Reeds, 10s. Voicing 2s. set extra. Pans, Bellows, Keys, &c. Complete List, Stamp.—W. HANDS and CO., Organ Builders, Bedford.

The English Mechanic
AND WORLD OF SCIENCE AND ART.
*FRIDAY, APRIL* 24, 1885.

## STEEL PLATES FOR BOILERS AND SHIPS.

THE loss of the new telegraph ship *Magneta*, which left the Thames early in March *en route* to Singapore, will do something to attract attention to the paper read by Mr. Parker at the recent meeting of the Institute of Naval Architects, for the assumption is that the vessel has foundered in consequence of a collision or through the bursting of one of her boilers. The *Magneta* has not been sighted or heard of since leaving the Channel; but one of her boats was seen 200 miles off Cape Finisterre, and appeared to have been properly lowered, though there was no apparent evidence of its having been occupied. There is too much reason to fear that this new, well-equipped, and well-found steamer has sunk with all hands on her maiden voyage. The vessel, which measured over 1,000 tons, was built of steel to Lloyd's rules, and was a sister vessel to the *Electra*, both being recent additions to the fleet of the Eastern Extension, Australasia, and China Telegraph Company, and both specially designed and fitted for the work of cable repairing. In fact, the *Magneta*, so far as human foresight can go, was as capable of battling with storms as any vessel that ever left port; and although there is great probability that she met with rough weather soon after clearing the Channel, there is no reason to suppose that she foundered from sheer inability to withstand a storm. Her engines were of the usual compound, surface-condensing, direct-acting type, capable of indicating 1,400 horse-power, and were supplied with steam by two single-ended cylindrical multitubular steel boilers, with three corrugated furnaces in each. She had, therefore, ample power for a vessel of her size; and it is not easy to suggest any probable cause for her loss and the total disappearance of her living freight beyond those above indicated. The vessel may, it is true, have been smothered by some terrific sea; but she was not overladen, or anything approaching it, and ought to have weathered any storm that she is likely to have encountered. Collision may have sent her to the bottom, and the other vessel as well; but even then we should expect that some of those on board would have saved themselves in the boats, of which there were six—two lifeboats, two cable cutters, hung in patent davits, a gig, and a dinghy. Most engineers will be loth to think that the *Magneta* was lost through a boiler explosion; but it is not impossible that some of the well-found and seaworthy steamers which have left port and have never been heard of again have foundered in consequence of a boiler explosion. The paper by Mr. Parker, of Lloyd's, above referred to, gave an account of some experience with thick steel boiler plates, and the discussion which followed it shows clearly that very little definite knowledge is available as to the cause of the peculiar behaviour of steel plates occasionally. An ordinary cylindrical marine boiler, 16ft. long and 13ft. in diameter, designed for a pressure of 150lb., burst under the hydraulic test when 240lb. was applied, the fracture extending completely across one of the shell plates, and to a slight extent also into the adjoining plate. The boiler was made by a firm having large experience with the material, and the steel came from works which enjoy the reputation of producing steel second to none in the country. The plates were all tested at the works, and fulfilled the requirements of Lloyd's Register and the Board of Trade; in fact, the sample from the plate stood a tensile strain of 29·6 tons per square inch with an elongation of 20 per cent. in a length of about 8in., whilst strips cut from it were bent almost double cold. The plate, however, was exceptionally large and heavy, being 20ft. long, 5ft. 6in. wide, 1¼in. thick, and weighed 2 tons 16cwt. In making up, all the holes were drilled, and the plate, after being heated in a furnace, was bent to the required curvature in a pair of vertical rolls. The plate, in fact, was treated exactly as other steel plates were and are treated, and yet it failed under a strain of less than one-fourth that sustained by the sample cut from it, the fracture indicating that the metal did not possess any ductility, stretch, or elongation whatever. So serious a result as that naturally produced considerable consternation, and the facts coming to the knowledge of the committee of Lloyd's Register, Mr. Parker was instructed to investigate the matter. On arriving at the boiler-making works he found a sister boiler, which was tested in his presence up to 300lb. and carefully gauged without exhibiting the least sign of deflection or yielding. An examination of the testing appliances showed that it was impossible for an abnormal pressure to be exerted, and as the metal had passed the mechanical tests, it became obvious that some change had been effected in its nature by the manipulations it had undergone in the boiler shop. Accordingly one of the plates was heated and bent in the presence of Mr. Parker, who noticed that the heat was far from uniform, one end being of a dark-red, or nearly black, heat, which gradually cooled down to a blue heat at the other end. The plate was then bent by passing it six times through the rolls, and by the time the operation was complete one end was nearly cold, while the other remained at a blue heat. Such unequal heating as that is believed to set up strains in the plate of a dangerous character, which are aggravated by rolling, and it is generally admitted that it is safer to work steel cold or red-hot than at any intermediate heat. Nothing definite, however, is known as to the intensity of the strains so set up; but from tests made with a number of pieces cut from the fractured plate it was proved that the metal ranged in tenacity from 29·5 to 33·1 tons, while the elongation varied from 21·8 to 28·1 per cent. in a length of 8in. As Mr. Parker says, a range of nearly 4 tons in the tensile strength of a plate of mild steel is very unsatisfactory; but when specimens of the plate were submitted to five independent metallurgists for analysis it was found that the carbon was high, ranging from ·26 to ·33, and that consequently the metal was capable of taking a temper and becoming hard and brittle. With the view of ascertaining the effects of rolling on the ductility and tenacity of such metal, a slab containing about the same amount of carbon as that found in the fractured plate was obtained from the works, and rolled at one heat down to ⅜in. in thickness. Such a slab, if rolled to 1¼in., would have given an estimated tenacity of 30 to 40 tons; but rolled to ⅜in. it was found that the tenacity had been increased to from 35 to 41 tons, with an elongation of from 21 to 24 per cent. in a length of 8in. Some pieces were then made hot and quenched in water, with the effect of sending up the tenacity to 44 and 45 tons, but reducing the stretch to nothing at all. Strips from the fractured plate heated and quenched broke short without any bend whatever. It seems, therefore, to follow that the plate which gave way must have become partially tempered by the heating and cooling to which it was subjected in order to roll it into the required form. The fact that the tenacity of such steel can be raised considerably by the amount of work put into it is well known: it has been increased as much as 50 per cent.; but great tensile strength is of no value at all if the metal is liable to take temper in the course of careless or ignorant annealing. It is doubtful whether there is any better material than mild steel for boiler plates, but it should have a very low percentage of carbon, and the plates after drilling should be thoroughly annealed. The bending into shape may be done either hot or cold; but if the former state is chosen care should be taken that the heating is uniform. As that cannot be always depended upon, some makers allow the plates to cool in the furnace, and when that has become cold they remove the plates and roll them into form cold. Steel makers are nearly all agreed that plates more than 1in. thick with a tenacity of more than 30 tons must contain so much carbon that they are unsuitable for boiler-making; and except amongst steel makers it does not seem to be known that the thicker the plate the more brittle and erratic in its behaviour it must become. The rules of Lloyd's Register require boiler plates to have a tensile strength of 26 to 30 tons per square inch, but the desire to use steam of higher pressures has brought to the Committee many requests from manufacturers and engineers to allow a strength of 32 tons. As the tendency is to use thicker and thicker plates it would seem to be advisable to put the limit at 30 tons and endeavour to insure the use of steel which cannot possibly become brittle under any treatment. Some manufacturers and engineers, however, contend that the mischief is done by putting work upon the plates when unequally heated. If plates of the kind are locally heated and allowed to cool no injury is done, but if, while it is locally heated, the form of the plate is changed so as to disturb its molecular arrangement, then internal strains are set up which may produce cracks. If there is so much risk in fashioning steel plates into the shape required it would seem advisable to limit that risk by insisting on the use of milder steel, and neglecting the demand of some makers for leave to use metal having a tenacity of 34 tons, although the fullest advantages from the use of steel are to be obtained only by lightening the structures. The makers of plates are rarely consulted by engineers as to the best sizes of plates to use: they are simply asked to supply plates of given dimensions, and do so as a matter of business without asking questions; but they know very well that the material they produce if worked when "blue hot" becomes treacherous. They also know that plates 1¼in. thick must contain more carbon than ⅜in. plates to give the same tensile strength. On the other side it is contended that a satisfactory steel can be produced which will have a tensile strength up to even 40 tons. In view of all the facts, or, rather, such facts as are available, it becomes a question whether the makers of marine boilers will not have to reform their patterns, and dispense with plates so thick as 1¼in. Referring to the article on the "explosive energy in steam boilers" on p. 421, last volume, it will readily be understood that a marine boiler is, from the volume of water it contains, a tremendously destructive engine if it should happen to fail when under a pressure of 100lb. on the square inch, and although there is little or no evidence to support the view, it is impossible to believe that boiler explosions never occur at sea. On the contrary, knowing as we do that land boilers do sometimes explode although they have previously passed satisfactory tests, there is ground at least for a suspicion that some of the steamers which have left port never to be heard of again have foundered in mid-ocean because they have been broken in two by the explosion of a boiler. Mild steel has also come into much favour for shipbuilding, and a very excellent material it is for the purpose; but because it has a high tensile strength there has been, in the opinion of many competent judges, too much haste to reduce thickness, and not a few vessels built of steel, or at least having steel plates, have exhibited unmistakable signs of dangerous straining. The subject deserves the serious attention of both the naval architect and the marine boiler maker, and it is improbable that recent events will pass unnoticed by those who regulate the dimensions of boiler plates and the scantlings of vessels.

## THE SPORTSMAN'S EXHIBITION.

THE Sportsman's Exhibition was opened at the Agricultural Hall on the 16th inst. The collection of boats of all kinds is, as usual, a good one, while carriage-building is still better represented. Guns are exhibited in great variety, from the great double-barrelled punt gun to the miniature rifle and the four-barrelled breech-loading hammerless pistol. Messrs. J. Platt and Co. exhibit a waterproof ventilated covert coat, which is so ingeniously arranged that the horseman can keep the driving rain from finding its way between the saddle and his thighs. That is managed by means of an "apron," buttoned inside. This garment is completed with a pair of waterproof gaiters, and certainly conveys the impression that nothing more can be wanted as protection against the weather. The angler will find a good display of rods and tackle, while at the stand of Messrs. Williams he will be able to examine what is said to be the only perfect rod-joint fitting, in the shape of a patent screw cap. Athletic sports, and indoor and outdoor games, are well represented, and there are several stands left from the Building Trades Exhibition, amongst which may be noted Messenger's portable greenhouses, which can be taken to pieces and removed as tenants' fixtures. The galleries are, as usual, occupied by "cycles," but, with the exception of one exhibit, where several "record" machines are shown, there is nothing very attractive or novel. The well-known patterns are shown mostly by agents, which, in one sense, is an advantage, as machines by different makers can be compared at the same stand. Holloway's improved wheel will attract some attention, as it is driven by tangential spokes in the plane of the rim. The two hubs of each wheel are kept apart by rods, and between them is a wheel with arms, which is fixed to the axle, and connected to the rim by spokes set at a tangent. This arrangement makes a very strong wheel, and the weight can be reduced, as only half the number of side spokes are required. The Metropolitan Machinists' Company exhibit several machines, which should be examined and compared with the prices charged. They include a safety roadster and a carrier tricycle. Burdess and Townsend exhibit some of their "Sterling" machines, with the new patent screw-steering device, a feature that is receiving some attention from other makers, and also one fitted with speed and power gear, which deserves the notice of those who reside in a hilly district. Such other novelties as are exhibited we have already described in our notice of the Stanley Club Show, which appeared in No. 1037.

## THE AMATEUR WORKSHOP. — VI.

### Planing Machines—Hand Gear.

FROM the numerous gears open to our choice one is rather puzzled which to adopt, for the number was by no means exhausted in our last article, since we did not so much as touch upon the link-driven machines, to which I hope to make some allusion after I have disposed of those actuated by cogwheels. In reference to these last, my intention is to describe first a hand-driven machine; then secondly I wish to show how the same machine may be driven by power gearing, and lastly how the two—hand and power gears—may be so combined that either may be employed at pleasure.

Taking up the hand gear in the present article, Fig. 55 shows it it in end view, A being the pinion, B the rack, C the pinion shaft, D the cross handle, and E, E the plummer blocks which form the spindle bearings. The pinion (Figs. 56, 57) has 11 teeth of $\frac{3}{4}$in. pitch, and its pitch diameter measures $2\frac{5}{8}$in., while the cross is 2ft. 3in. over. Assuming that the hands grasp it at a radius of one foot only, and exert a pressure of 15lb., we should have a force of

$$1\tfrac{5}{16}\text{in.} : 12 :: 15 : 137{\cdot}4\text{lb.}$$

acting at the pitch lines of the pinion and rack, which would be sufficient for such light cutting as a machine of this kind would be expected to accomplish. But 15lb. is a moderate estimate, since men of ordinary strength will exert a force of from 20lb. to 25lb. at continuous labour of this character; so that without increasing the size of the cross, a cutting force of 200lb. may be safely assumed as within the ordinary capability of this machine.

Then regarding the strength of the teeth. The pinion teeth are strongly drawn (Fig. 58), but are of necessity weaker than those of the rack. Still, these teeth, if made of cast iron of average strength, and unshrouded, would require a load of 204lb. acting at their points to break them off. But I have drawn them shrouded up to the pitch line, by which their strength is increased one half. Further, to ensure durability as well as an increase of strength, I should cast the pinion in gun metal or phosphor bronze, the last named to have the preference. Also note that the rack (Figs. 56 and 57) is shrouded to the pitch line in order that the regular motion of the teeth may be assisted by the frictional contact of the two shroudings. And to assist those who would be unable to strike out their own teeth, I have drawn them by rolling circles appropriate for strength and perfect working, and have given two teeth of both pinion and rack (Figs. 58, 59), to full size, with the centres for the flank curves.

I intended, in the first place, to have constructed the rack of the type shown in Fig. 52 p. 46; but I considered that it would be a little more troublesome to make, and since the table is fitted with outside angle-slides, its liability to tip is *nil*, if the loose strip is kept in place. The friction shrouding, in conjunction with the angle slides, will insure the absence of waviness in the cut, and of chatter in the table.

Since so much depends upon the smooth action of the rack and pinion, too much care cannot be taken with their patterns. The pinion will be made in three pieces (Fig. 57), the body A, the top and bottom shrouds B, C. The body will be turned out of a bit of dry solid mahogany to $3\frac{3}{32}$in. diameter, that being the diameter measured outside the points of the teeth, by 2in. in thickness, the grain of the wood to run with the teeth. It may be chucked between centres, but the better way is to turn it upon the face chuck. This allows of the more ready marking out of the striking lines, and it is also convenient for the boring of a shallow recess upon each face for the reception of studs, fig. 57, D, turned upon the shrouds; the shrouds being of necessity left loose from the toothed body for moulding, yet requiring to be maintained truly central. When turning, therefore, face one side, and strike upon it in the lathe the outer diameter $= 3\frac{3}{32}$in., the pitch line $= 2\frac{5}{8}$in., and the circle of the roots $=$ 2in. Then bore the shallow recess, say 1in. diameter, turn the outside, allowing as much taper only as can be detected by the calipers, and re-chuck by means of the recess, in order to face the other side. That also will receive its lines, and be recessed in like fashion.

Upon one side divide the $2\frac{5}{8}$in., or pitch circle, into eleven points of equal division $=$ the pitch $\frac{3}{4}$in. Draw lines from the centre through the pitch points to the outside of the pinion in two or three places, and square them over to the side opposite, which lines will form the starting points for dividing out the pitch centres upon that side also. Set the spring dividers to the half-width of tooth, and from each pitch point as a centre mark the width of all the teeth in succession (Fig. 58). Strike the roots with a $\frac{1}{4}$in. radius, whose centre is on the circle formed by the points of the teeth; holding a slip of wood curved to the radius of that circle against it, to prevent the divider-leg from slipping. Strike the points with a $\frac{9}{16}$in. radius, whose centre is on the pitch line. Make no difference in the setting of the dividers for the thickness of the teeth for either side of the wheel, since sufficient taper can be imparted to so shallow a pattern in the glasspapering. A hollow is worked in the roots for increase of strength.

Saw out the spaces between the teeth roughly with a tenon saw, and work with a chisel and paring gouge, using a small mahogany straightedge, of about 5in. or 6in. in length, by $\frac{1}{4}$in. thick and $\frac{3}{8}$in. wide only, so that it will slide between the teeth, the straightedge to be coloured with chalk or red lead. The aim should be to work the flanks of the teeth so level that the chalk should whiten almost the entire surface from end to end before resorting to glasspaper. The glasspaper should not be regarded as aiding in any degree in the getting the teeth straight or to shape, but as simply rubbing down the last asperities left by the edge tools. The sides of the teeth should be checked with the trying square, or else with a set square tried up from a level block, upon which the pinion is laid, and if the teeth are square and straight, no taper need be given to so shallow a wheel. I should put none at all in this instance, the better to insure continuous contact along the flanks.

The shrouds, fig. 57, D, are both turned to $2\frac{3}{4}$in. diameter, which allows of $\frac{1}{8}$in. for cleaning up in the casting; their studs fit easily in the recesses at each end of the pinion, and a $\frac{3}{4}$in. print on one or both of them indicates the size of the central core.

The pattern of the rack (Figs. 56, 57, 59, 60), will be made from a straight-grained piece of mahogany planed to 2ft. $1\frac{1}{2}$in. by 2in. by $1\frac{7}{16}$in.; hence the teeth will be cut from the solid—not necessarily however, since they could as well be fastened on. The pitch line, and the two striking lines, and the root-line (Fig. 59), will be gauged from one face upon both edges, and the teeth centres pitched out and squared over. The flanks will be struck with a $1\frac{3}{16}$in. radius from the line A, Fig. 59, the faces with a $\frac{5}{8}$in. radius from the line B, and the working-out will be performed as before.

Two strips, each 2ft. $1\frac{1}{2}$in. by $1\frac{1}{4}$in. by $\frac{3}{8}$in., will be screwed upon the sides to form the half-shrouding, and six lugs (A, A, Figs. 57 and 60), $\frac{3}{4}$in. thick, and of the shape and size there indicated, will be attached to these for bolting to the underside of the table. Two will be fastened on near each end, their centres being $\frac{3}{4}$in. in and two in the exact centre.

The form of bearing which I propose employing for the pinion shaft is drawn in fig. 61, the simple boss in fig. 62, and either of these may be selected, a slight modification of the tappet lever being necessary in the different bearings. In reference to the bearing pattern I need say little, since the dimensioned views are plain enough. The semicircular portion of the block, and also that of the cap, will be cut out to $\frac{3}{4}$in. diameter, and if the shouldered portions of the cap which come within the block are made a tight fit in the patterns, the castings will be sufficiently full to allow of a little filing. The collars A A, which increase the length of bearing, are abutted together in halves, and glued on the face-plate with a paper-joint for turning. These must be put loosely upon the bearing-pattern with skewers, but they will be better fastened upon the cap. The cores for the ┳-headed bolts will be set in round prints, and a core-box will be necessary. Or simple studs screwed to a depth of about $\frac{3}{4}$in. may be used instead of bolts. The holes B B should be drilled for the tight-fitting bolts. The bearing will be bored while held on an angle-plate bolted to the face-chuck of a lathe. An oil-hole will be drilled in each cap.

After these are bored it is essential that they be set parallel upon the bracket facings prepared for their reception. The bearing feet and the bracket-facings will be first filed and checked, independently of one another. Recesses will be chipped out upon the brackets to take the joggle pieces on the bottoms of the blocks. Then both will be compared together, and adjusted, until the bearing-centres measure exactly $2\frac{1}{4}$in. below the top of the bearers of the bed. To check this dimension, lay a narrow straightedge of steel or wood along the bottom of the bored hole, and try its parallelism by measurement from another straightedge laid over the top of the bearers; in this case the distance would be $2\frac{1}{4}$in. plus $\frac{3}{8}$in. to the bottom of the bore. Of course, before this can be done, the hole A, Fig. 55, must be drilled through the side of the bed for the spindle, and as this is not a bearing it may be drilled to $1\frac{1}{8}$in.

The spindle should be at exact right angles with the sides of the bed, and the truth of the bearings in this direction may be tested by straining a fine cord from corresponding edges of the bores within and without, and then placing a straight-edge square across the bed just over the cord and sight down, when a slight departure from parallelism will be apparent. When satisfactory results are obtained $\frac{1}{4}$in. bolt-holes can be drilled

FIG 55.

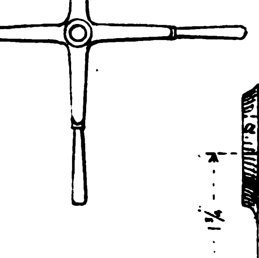

FIG. 64.

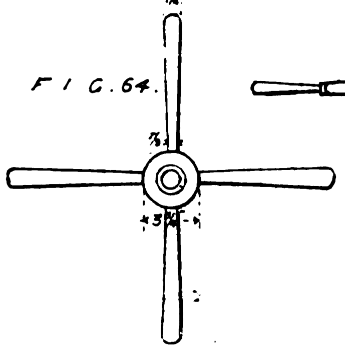

FIG. 61.

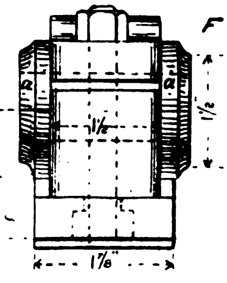

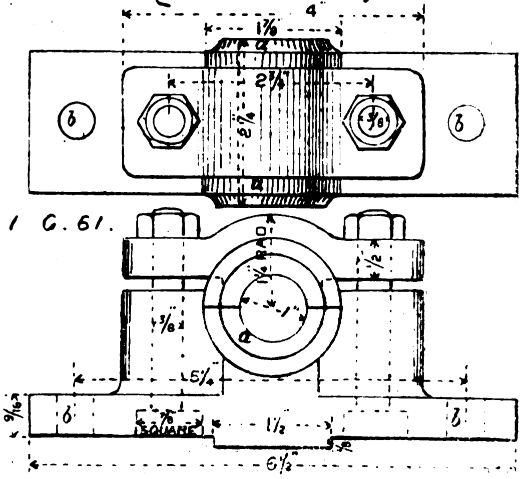

at the centres marked, Fig. 61, through blocks and brackets simultaneously, the blocks being cramped in position. Or drill through the blocks first, the holes being marked thence on to the brackets.

Supposing that, instead of the plummer blocks, the bosses shown in Fig. 62 are used, as giving less trouble, the marking of the centre must be done from the top of the bed as before, and the bed placed under a drilling machine. A twist-drill also should be employed for a deep hole, where much accuracy is required. But if a ratchet-brace only can be employed, the labour would be lessened, if the hole were first cast to ¾in. or ⅞in. diameter; but then if it happens to be out of truth, the drill will follow it. In that case the only course is to file the hole fairly true, and nearly to size, and then broach it out. This simply means taking a little more time over the job.

We will now get the castings of the pinion, and the rack, and fit them up. No chipping ships were put upon the back of the latter, but we have five strips instead upon the under-side of the table (Fig. 8, p. 468, Vol. XL.) These strips will now be reduced to ⅛in. thick, and a steady bearing secured thereon for the rack, the filing being continued until the points of the teeth measure exactly 1 3/16in. from those faces of the table which run upon the bearers.

From the tooth points also measure back ¼in. bare, and mark the pitch-lines on both shroudings with a scribe. File or plane those edges to the scribed lines, and check those also with the sliding faces of the table. They should measure uniformly 1⅛in. full from those faces.

The next point is to set the rack sideways, and drill the holes for the set screws, Fig. 60. Its position will be in the centre of the table, and parallel with its edges. A ½in. clearing-hole will be wanted in each lug, ½in. tapping-holes being drilled in the table to centres marked off from the holes in the lugs, and tapped to receive six set-screws to the dimensions of Fig. 57, E E. The rack may then be screwed in place.

The pinion will be bored to 1in. in the lathe, and the shrouds will be turned to 2⅝in. diameter, and one shroud (the inner one) should be faced to run against the bearing. A keyway, ¼in. by ⅛in. will be filed, and a shouldered steel key made, to drive in from the unfaced end of the pinion. A steel spindle, 1ft. 8½in. long, and turned through its whole length to 1in. diameter, will receive the pinion at one end, and the cross-handle at the other, both alike being keyed on.

Since both the pinion and the rack teeth are 2in. wide and half shrouded, the ends of each will need a little easing, to allow of their free working between the shrouding. This easing will be done with a file.

A cast-iron hand wheel having handles screwed into its rim (Fig. 63), has a neat appearance, but involves the making of a special pattern. while the cross, (Figs. 55 and 64), can be made without this trouble. The cross might be made in one of three ways. Thus a smith would make it easiest as a forging welded together and trimmed up afterwards (Fig. 65), a moulder would find it easier to cast four plain wrought-iron rods into a central socket boss (Fig. 66), while a fitter or turner would prefer to turn four handles and screw them into a plain centre of cast or wrought iron (Fig. 64). In either case, the work is of the simplest character.

In the first instance, Fig. 65, the two pieces forming the cross arms would be welded one on the other, the boss being done at a second heat. In the second (Fig. 66), the pattern of the boss piece would have four round points about 3 or 4 inches long, fastened on at the centres of the rods, to indicate their position in the mould, and those portions of the rods inclosed by the bosses would be "jagged" (Fig. 67), to prevent loosening. In the third the ends of the turned handles are screwed into the boss to a depth of about ¾in., a flat being filed or bored to a slight depth to give bearing surface. In either case a hole will be bored, and keyway filed, and steel key made similar to that for the pinion.

Before the pinion is finally keyed on, the caps of the bearings will be loosened, the shaft thrust through from the outside, the table run to one end out of the way, and the pinion slipped over its proper end, and there keyed. The table may then be brought back, when its rack teeth will engage with those of the pinion.

# ASTRONOMICAL NOTES FOR MAY, 1885.

### The Sun.

| 26 | 11 56 48·08 ,, | 4 13 41 | 21 12 15 | 4 16 52·67 |
| 31 | 11 57 25·69 ,, | 4 34 1 | 21 58 51 | 4 36 35·45 |

The method of finding the Local Sidereal Time at Mean Noon at any other Station will be found on p. 355 of Vol. XL.

Spots and faculæ continue to appear on the disc of the Sun, although, as previously stated, the period of maxima has now definitely passed.

After May 22nd there will be no real night in any part of the British Islands.

### The Moon

Enters her Last Quarter at 8h. 43m. on May 7th, and is New at 3h. 17·5m. in the afternoon on the 14th. She will enter her First Quarter at 5h. 45·1m. in the early morning of the 21st, and be Full at 8h. 30·9m. p.m. on the 28th.

| Day of Month. | Moon's Age at Noon. | Souths. |
|---|---|---|
| | Days. | h. m. |
| 1 | 16·3 | 1 24·2 a.m. |
| 6 | 21·3 | 5 20·0 ,, |

| 16 | 1·9 | 1 52·1 p.m. |
| 21 | 6·9 | 6 35·6 ,, |
| 26 | 11·9 | 10 32·3 ,, |
| 31 | 16·9 | 1 42·8 a.m. |

The Moon will be in conjunction simultaneously with Mercury and Mars at 4 a.m. on the 13th; with Venus at 6 o'clock the next evening; with Saturn at 3 p.m. on the 16th; and with Jupiter at 3 a.m. on the 21st.

### Mercury

Is a Morning Star throughout the month, attaining his greatest elongation from the Sun West (21° 45′) at 1 p.m. on the 25th. In one sense he is not particularly well placed for the observer, inasmuch as he does not rise sufficiently long before the Sun to be readily caught with the naked eye. His angular diameter diminishes from 12″ on the 1st to 7·2″ by the last day of May.

| Day of Month. | Right Ascension. | Declination North. | Souths. |
|---|---|---|---|
| | h. m. | ° ′ | h. m. |
| 1 | 2 14·3 | 13 23·4 | 11 36·0 a.m. |

### Venus,

Coming as she does into superior conjunction with the Sun at 5 p.m. on the 4th, is actually invisible during the earlier part of May, and practically so during the whole of it; though, even could she be seen, her minute circular disc subtending an angle of 9·6″ only, would present a singularly uninteresting spectacle in the telescope.

|---|---|---|---|
| | h. m. | ° ′ | h. m. |
| 1 | 2 33·0 | 14 18·5 | 11 54·7 a.m. |
| 6 | 2 57·1 | 16 8·8 | Behind the Sun. |
| 11 | 3 21·8 | 17 58·9 | 0 4·0 p.m. |
| 16 | 3 46·9 | 19 37·3 | 0 9·4 ,, |
| 21 | 4 12·4 | 21 2·6 | 0 15·2 ,, |
| 26 | 4 38·4 | 22 13·3 | 0 21·5 ,, |
| 31 | 5 4·8 | 23 8·3 | 0 28·2 ,, |

It will be seen from the above Ephemeris that Venus travels over a good deal of Aries, and about half-way across Taurus.

### Mars,

For the purpose of the observer, is invisible. Of the Minor Planets,

### Ceres

Is rapidly approaching the West. We give, as usual, her places at intervals of ten days.

| Day of Month. | Right Ascension. | Declination North. | Souths. |
|---|---|---|---|
| | h. m. | ° ′ | h. m. |
| 1 | 12 50 7 | 9 49·3 | 10 10·7 p.m. |
| 11 | 12 46·0 | 9 18·2 | 9 26·8 ,, |
| 21 | 12 43·7 | 8 29·1 | 8 45·1 ,, |
| 31 | 12 43·8 | 7 25·0 | 8 5·8 ,, |

Starting thus from a point to the South-West of ε Virginis, Ceres travels in a retrograde direction away from that star.

### Pallas

Is nearer the West still.

| Day of Month. | Right Ascension. | Declination North. | Souths. |
|---|---|---|---|
| | h. m. | ° ′ | h. m. |
| 1 | 11 42·7 | 18 36·9 | 9 2·9 p.m. |
| 11 | 11 44·7 | 19 31·6 | 8 25·5 ,, |
| 21 | 11 49·0 | 19 55·6 | 7 50·5 ,, |
| 31 | 11 55·2 | 19 54·7 | 7 17·4 ,, |

The path thus indicated carries Pallas from a point some 3° North of β Leonis into the confines of Coma Berenices.

### Juno

Souths a little later on, and is, *pro tanto*, rather better placed for the observer.

| Day of Month. | Right Ascension. | Declination North. | Souths. |
|---|---|---|---|
| | h. m. | ° ′ | h. m. |
| 1 | 13 40·2 | 1 55·2 | 11 0·1 p.m. |
| 11 | 13 33·6 | 2 38·1 | 10 14·2 ,, |
| 21 | 13 28·6 | 3 4·3 | 9 29·9 ,, |
| 31 | 13 25·4 | 3 13·8 | 8 47·3 ,, |

The above Ephemeris shows that the short retrograde arc described by Juno lies wholly in a barren region in Virgo.

### Jupiter,

Too, is approaching the West, and must be looked at as soon as it is dark enough. His angular diameter decreases from 36·4″ to 33·4″ during the month, and he will be in quadrature with the Sun at 3 p.m. on the 17th. Of course, he is at vastly too great a distance from the earth to exhibit phases; but the careful observer with adequate telescopic power may now note a perceptible *shading* on that limb of the planet furthest from the sun.

### Jupiter.

| Day of Month. | Right Ascension. | | Declination North. | | Souths. | | |
|---|---|---|---|---|---|---|---|
| | h. | m. | ° | ′ | h. | m. | |
| 1 | 9 | 54·6 | 13 | 58·1 | 7 | 15·1 | p.m. |
| 6 | 9 | 55·3 | 13 | 53·5 | 6 | 56·1 | ,, |
| 11 | 9 | 56·3 | 13 | 47·5 | 6 | 37·5 | ,, |
| 16 | 9 | 57·5 | 13 | 40·1 | 6 | 19·1 | ,, |
| 21 | 9 | 59·1 | 13 | 31·3 | 6 | 0·9 | ,, |
| 26 | 10 | 0·8 | 13 | 21·1 | 5 | 43·0 | ,, |
| 31 | 10 | 2·8 | 13 | 9·7 | 5 | 15·3 | ,, |

So that Jupiter, starting from that part of Leo a little to the North of Regulus, travels in the direction of that Star, and will be found less than a degree North of it on the last night in May.

### Saturn,

Rising and Southing now in bright sunshine, may be held to have left us, for all purposes of the observer, until the autumn.

### Uranus

Souths not long after 9 p.m. at the beginning of May, and towards the end of it is on the meridian in twilight. Hence, he should be looked for as soon after dark as may be. His angular diameter decreases quite insensibly from 4″ to 3·8″ between the first and last days of the month.

| Day of Month. | Right Ascension. | | Declination North. | | Souths. | | |
|---|---|---|---|---|---|---|---|
| | h. | m. | ° | ′ | h. | m. | |
| 1 | 11 | 58·7 | 0 | 58·6 | 9 | 18·9 | p.m. |
| 6 | 11 | 58·2 | 1 | 1·7 | 8 | 58·7 | ,, |
| 11 | 11 | 57·8 | 1 | 4·2 | 8 | 38·6 | ,, |
| 16 | 11 | 57·4 | 1 | 6·3 | 8 | 18·6 | ,, |
| 21 | 11 | 57·1 | 1 | 7·9 | 7 | 58·6 | ,, |
| 26 | 11 | 56·9 | 1 | 9·0 | 7 | 38·7 | ,, |
| 31 | 11 | 56·8 | 1 | 9·6 | 7 | 19·0 | ,, |

This almost imperceptible retrograde path lies to the West of η Virginis, and trends in a direction beneath β in Virgo.

### Neptune

Comes into conjunction with the Sun at 4 p.m. on the 13th, and is, of course, wholly invisible.

### Shooting Stars

Are very uncommon in May. The night of the 18th is the likeliest one on which to watch for them with any prospect of being rewarded.

### Greenwich Mean Time of Southing of Ten of the Principal Fixed Stars on the Night of May 1st, 1885.

| Star. | Souths. h. | m. | s. | |
|---|---|---|---|---|
| δ Crateris | 8 | 33 | 54·16 | p.m. |
| β Leonis | 9 | 3 | 25·25 | ,, |
| β Corvi | 9 | 48 | 27·66 | ,, |
| α Canum Venaticorum | 10 | 10 | 41·60 | ,, |
| Spica Virginis | 10 | 39 | 6·61 | ,, |
| η Ursæ Majoris | 11 | 2 | 54·82 | ,, |
| Arcturus | 11 | 30 | 14·81 | ,, |
| α Libræ | 12 | 4 | 15·82 | ,, |
| α Coronæ | 12 | 49 | 26·00 | ,, |
| α Serpentis | 12 | 58 | 11·78 | ,, |

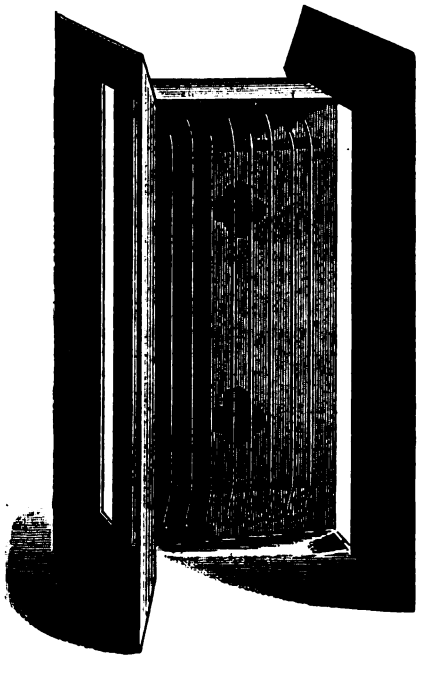
The method of finding the Greenwich Mean Time of Southing of either of the Stars in the above list for any other night in May, as also that of determining the local instant of its Transit at any other Station, will be found on p. 356 of Vol. XL.

## THE ÆOLIAN HARP.

THE following description of the Æolian harp with illustration of an improved form is extracted from an article in *La Nature*:—According to a generally credited opinion, it is to Father Kircher, who devised so many ingenious machines in the seventeenth century, that we owe the first systematically constructed model of an Æolian harp. We must add, however, that the fact of the spontaneous resonance of certain musical instruments when exposed to a current of air had struck the observers of nature in times of remotest antiquity.

Without dwelling upon the history of the Æolian harp, we may say that in modern times this instrument has been especially constructed in England, Scotland, Germany, and Alsace. The Æolian harp of the Castle of Baden Baden, and those of the four turrets of Strasburg Cathedral are celebrated.

We shall first describe Kircher's harp, which this Jesuit savant constructed according to an observation made by Porta in 1558. The instrument consists of a rectangular box, the sounding board of which, containing rose-shaped apertures, is provided with a certain number of strings stretched over two bridges and fastened to pegs at the extremities. This box carries a ring that serves for suspending it. Kircher recommends that the box be made of very sonorous fir wood, like that employed in the construction of stringed instruments. He would have it 1·085 metre (43in.) in length, 0·434 metre (17in.) in width, and 0·217 metre (9in.) in height, and would provide it with fifteen catgut strings, tuned, not like those of other instruments to the third, fourth, or fifth, but all in unison or to the octave, in order, says he, that its sound shall be very harmonious. The experiments of Kircher showed him the necessity of employing a sort of concentrator in order to increase the force of the wind, and to obtain all the advantage possible from the current of air that was directed against the strings. The place where the instrument is located should not, according to him, be exposed to the open air, but must be a closed one. The air, nevertheless, must have free access to it on both sides of the harp. The force of the wind may be concentrated upon such a point in different ways; either, for example, by means of conical channels, or spiral ones like those used for causing sounds to reach the interior of a house from a more elevated place, or by means of a sort of door. These latter, two in number, are adapted to a kind of receptacle made of boards, and presenting the appearance of a small closet. In the back part of this receptacle there is a slit, and in front of this the harp is hung in a slightly oblique position. The whole posterior portion of the apparatus must be situated in the apartment, while the doors must remain outside the window. In later times the Æolian harp has been improved by Messrs. Frost and Kastner, whose apparatus is represented in the figure. It consists of a rectangular box with two sounding boards, each provided with eight catgut strings. In order to limit the current of air and to bring it with more force against the strings, two wings are adapted near the thin surfaces opposed to the wind, so that the current may reach each group of cords on passing through the narrow aperture between the obliquely inclined wing and the body of the instrument. The dimensions of the resonant box are as follows: height, 1·28 metre (50½in.); width, 0·27 metre (10½in.); and thickness, 0 075 metre (3in.). Distance between the two bridges, or length of the sonorous portion of the cords, about 1 metre (39·3in.); width of the wings, 0·14 metre (5½in.). Distance between the sounding board and the wings, 0 42 metre (16½in.). Inclination of the wings, 50 degrees.



The celebrated Æolian harps of the old castle of Baden Baden are entirely different, and merit description. One of them is formed of a resonant box, the construction of which differs from that of Æolian harps with a rectangular box, in that it is prolonged beyond the place occupied by the strings, and is rounded off behind. In the opposite side there are two long and narrow apertures. To prevent the apparatus from being injured by the weather, it is inclosed in a sort of case occupying the recess of the window in the old ruined castle in which it is exposed. Behind the harp there is a wire lattice door, the purpose of which seems to be to protect the instrument against the attempts of robbers or the indiscreet contact of tourists.

## COLOURED LACQUERS.

LACQUERS are frequently required to be coloured, either yellow or red tints. For yellow tints turmeric, Cape aloes, saffron, or gamboge are employed; for red tints, annatto and dragon's blood are used—the proportions being varied according to the colour required. Thus, for a pale yellow, about 1oz. of gamboge and 2oz. of Cape aloes are powdered and mixed with 1lb. of shellac. For a full yellow, ½lb. of turmeric and 2oz. of gamboge, and for a red lacquer, ½lb. of dragon's blood and 1lb. of annatto. The colour is also modified by that of the lac employed, the best pale or orange shellac being used for light-coloured lacquers, and dark-coloured shellac or seed-lac is used for the darker tints. For pale lacquers, sandarac is sometimes used with the shellac. Thus a pale gold-coloured lacquer is made with 8oz. of shellac, 2oz. of sandarac, 8oz. of turmeric, 2oz. of annatto, and ¼oz. of dragon's blood to one gallon of methylated alcohol. The most convenient method, however, of colouring lacquers, is to make a saturated solution of spirit in each of the colouring matters, and to add the solutions in different proportion to the pale lacquer according to the tint required; but the whole of the colouring matters are not generally used by the same makers, and solutions of turmeric, gamboge, and dragon's blood afford sufficient choice for ordinary purposes. The turmeric gives a greenish-yellow tint, and with the addition of a little gamboge, is the colouring matter employed in making the so-called green lacquer used for bronzed works. Another mode of making lacquer: Four ounces of shellac and ¼oz. of gamboge are dissolved by agitation, without heat in 25oz. of pure pyro-acetic ether. The solution is allowed to stand until the gummy matters not taken up by the spirit subside; the clear liquid is then decanted, and when required for use is mixed with eight times its quantity of spirit. In this case, the pyro-acetic ether is employed for dissolving the shellac, in order to prevent any but the purely resinous portions being taken up, which is almost certain to occur with ordinary spirit, owing to the presence of water; but if the lacquers were made entirely with pyro-acetic ether, the latter would evaporate too rapidly to allow time for it to be equally applied.

## HOW AN AMATEUR CAN MAKE A HIGHLY-SENSITIVE GELATINE EMULSION.*

FOR the benefit of those for whom this is written, I will give Dr. Eder's emulsion formula, with my method of working:—Dissolve 24 grammes of pure air-dried potassium bromide in 300cc. of distilled water, 30 to 45 grammes of gelatine are introduced, and the whole, after soaking half an hour, is placed in a water-bath at a temperature of 35° C. to 45° C. (95°—113° Fahr.) till the gelatine has dissolved and become clear; then take 30 grammes of silver nitrate and dissolve in 300cc. of water, and add ammonia drop by drop, stirring all the time, till the precipitate formed is re-dissolved, and the liquid becomes perfectly clear. The above operation can be performed in daylight. Now, by a weak ruby light, add the silver solution to the gelatine, a third at a time, and shake vigorously between each addition, and allow to cool down to 35° C. (95° Fahr.); shake again after the whole of the silver has been added, and at intervals; and rinse out remains of silver with 50cc. of water. Then replace the bottle in the water-bath, which should be at a temperature not exceeding 35° C., let it remain for an hour, allowing the water in the bath at the same time to cool down gradually. The temperature may be allowed to sink as low as 25° C. (77° Fahr.) without any fear of the gelatine setting; but the quantity of water should be sufficient to prevent the temperature falling lower. In this method the chemicals used should be the best procurable. The temperature should never exceed 40° C. (104° Fahr.) in the preparation of this emulsion, or fog will be sure to follow. When it has digested the required time, it is poured out into a large dish to set and to cool for a couple of hours, or a larger dish may be partly filled with water, and the one with emulsion placed in it to hasten its setting. After it is thoroughly set, squeeze it through coarse canvas with meshes about 2 to 3mm. apart into a large bowl of water, and well stir. Have a box about 1ft. square by 4in. deep covered with fine muslin or linen, so that the water may be poured out of bowl into box, which will let all water through, but retain the small particles of emulsion. Repeat the washing four or five times, for here lies the resulting rapidity of the plates. After well washing, allow to drain well, for it contains an excess of water which must be got rid of. After well draining, it is put into a bottle, dissolved, and filtered through chamois leather; it is then ready for coating the plates.

---

* By E. G. Wales, extracted from the *Photographic News*.

I will now give a description of the articles I use for heating, filtering, coating, &c. A zinc tray, 18in. long by 9 broad by 5 deep, with funnel soldered in near left-hand corner, to stand ½in. above the level of tray, so as to prevent any water accidentally going down into jugs whilst filtering. In this zinc funnel I place a glass—one which has a chamois leather spread over. The heat of the water in tray is sufficient to cause the emulsion to filter through rapidly. I have a box let into the dark-room from outside, which has a flange 4in. deep all round for the purpose of nailing it to the partition; on one side it has a hole 6in. square cut out, and a small box with flange is riveted on to it, from which the heat in larger box enters. I place my jar to receive the emulsion as it passes through the filter. On the top of large box I place the tray containing the hot water and emulsion-bottle, then I place a small oil-stove in box from outside, which keeps the heat at any desired temperature; by this contrivance all gases are entirely shut out of the room. A support will be needed under the larger box. For coating, I use two small jugs, one for pouring, the other to receive any surplus from plates coated and returned to filter· I use slate slabs for setting, and I find these much cooler than glass. For drying-racks, I use shelves the length of the room, with rows of oval holes cut in diagonally, or so that there shall be a space between the first row and third; the holes are cut larger and wider at the top than at the bottom, so as to prevent any part of the plate becoming damaged. I find this plan exceedingly good. For ventilation I get two stove-pipe elbows, and insert one at one end of the room near the floor, the other I connect with the chimney, thereby securing a good current of air amongst the plates. I find one thickness of the paper supplied by most stock-dealers perfectly safe; it is a good plan to have a thick plate of glass outside to keep inquisitive people from pushing a hole through the paper. I mention this through losing over nine dozen 5 by 8 plates from the attempt of a friend to rear himself up inside my dark room. Almost any developer is good for these plates; but I prefer, for out-door work, ferrous oxalate iron solution, one to four of oxalate solution.

## PHOTOGRAPHY FOR AMATEURS.*

THE amateur of architectural photography has a field of usefulness before him which combines more, perhaps, than any other branch of photography, the agreeable with the useful. Travel, picturesqueness of subject-matter, and a peculiar adaptation of it to the photographer's methods; a remarkable choice of effect in light and shade, and the enjoyment to the highest degree of the peculiar power of the camera; the rendering of detail of the most exquisite delicacy without interfering with the general effect, to such a degree, in fact, that a photographic negative magnified will give details which the unaided eye would never have seen in the object itself, are all combined in architectural photography in an exceptional degree.

To the proper rendering of architecture it is necessary that the amateur should provide himself with a square-plate camera or one with a reversible back. We prefer, and have used for some years, the former, as we find that many architectural subjects are more complete when square than when shorter in one dimension, but the reversible back gives a lighter outfit. It must have a swing back, but the side swing is not necessary, nor, indeed, is it desirable to use it in architecture, as it alters the relative magnitude of the details on the two sides of the view. The lens must be of the symmetrical type, and it is better to have a series of different foci. On a 6½ × 4¾ plate we employ a series of 4, 6, 8, and 10 inch foci, portable, symmetrical lenses, fitting the same flange. For an 8 × 8 plate these are supplemented by a 13-inch rapid symmetrical for both architecture and instantaneous views or groups. It is best to use always the smallest diaphragm possible, for hazy or out-of-focus architectural details are an abomination.

The subject should be studied carefully to get the best light and shade, which is generally with the sun about midway between the back and one side, but so as, at any rate, to secure to a certain extent the three dimensions of the building, if only one view is wanted; but if the architectural elevation is desired it should be taken with the greatest exactitude, placing the camera precisely opposite centre of the façade. The absolute vertical position of the ground glass should be secured by the use of the plumb line, for which we use a conical pistol bullet at the end of a black silk thread. No eye can determine, from the subject as seen on the ground glass, the absolute correctness of the perpendiculars, which is necessary to secure the correctness of the image. Take for instance the east façade of the Parthenon, in which the columns all converge slightly to a point over the centre of the building. There is no absolutely vertical line and no straight horizontal line, so that to the eye there is no rigid measure, but, having the glass absolutely perpendicular, whatever variation from the perpendicular exists in the building is recorded and can be measured on the plate. The side swing is to be avoided, because by swinging one side of the glass further from the lens we increase the image on that side.

Extreme perspective is to be avoided, not because it is incorrect, but because to make it seem correct the photograph must be seen at the distance of the focal length of the lens, but this must be risked when the subject does not come on the plate with a long-focus lens. The focus must be short enough to get in a complete subject, but in any case, if possible, get far enough from the subject to include the whole of it with a lens of not less focal length than the base lens of the plate. Further, if possible, and if the distances, &c., permit, get the whole subject in angle of 40 degrees.

Focus with full opening of your lens on the most distant part of the building, and then stop down to the very smallest diaphragm. We had all our lenses furnished with diaphragm openings half the diameter of the smallest the lens is sent out with—*i.e.*, down to $\frac{F}{80}$. Give abundant exposures, with development to moderate intensity, so that no glittering high lights occur on one side, and no shadows conceal detail on the other. The brilliant effect which is obtained, and is sometimes desirable, in landscape by extreme intensity of light and shade, implies in an architectural subject loss of the general illumination indispensable to it.

Never stop out the sky of an architectural photograph. The views of the classical scenes for sale in Rome and Athens, the views in Venice, &c., by professional photographers, in most cases are "improved" by having the skies carefully stopped out. This destroys all the sky outline, and, like a wash on an antique statue, leaves no indication of where the original has its termination. A spotted or stained sky is not half so grave a defect as the glaring white, hard, painted-out sky which cuts the edge of the subject like tin, and destroys the space and atmosphere, while it leaves the mind in doubt whether part of the view is not cut out as well. In photographs of classical ruins, this defect is destructive of their value, and when to it is added, as it often is, careless levelling of the camera, and consequent converging or diverging perpendiculars, they are really not worth carrying home, because they belie the subject in some of its most important qualities.

## THE FORMS OF LEAVES.

AT the recent meeting of the Linnean Society, Sir John Lubbock read a paper on this subject, dwelling in more detail on some points to which he had alluded in a popular manner in his lecture at the Royal Institution, and entering into some considerations which time did not then permit him to discuss (see p. 533, Vol. XL.) He had long been puzzled at the reason why some plants have cordate leaves, more or less elongated, and others palmate. Starting from a foliaceous expansion of a stem, the former was evidently the simpler type. It might be considered as derived from a simple form, as, for instance, the leaf of a grass. Such a leaf, gradually widened near the base, would give the heart-shaped form. He mentioned several plants which, although when mature they have palmate leave, produce as seedlings one or more rounded ones before developing the final form. He had suggested that the cordate shape was the earlier from which the palmate was developed. The interesting consequence would follow that if in the same genus some species were cordate and others palmate, the latter were of later origin. This explanation presupposed that the palmate form, at any rate, under certain circumstances, presented greater advantages. Sir John suggested that this might have reference to the power of self-support and of resisting wind. The weight of the leaf and the force of the wind might be considered as if they were concentrated on the central point of the leaf. Now in palmate leaves the centre would be nearer the point of support, and the resistance to any given force, therefore, would be more effectual. This point was illustrated by experiment. Broad leaves, however, were of two main types—cordate, with veins following the curvature of the edge, and palmate, or lobed leaves, with veins running direct to the margin. Now, the fibres constituting the so-called veins of leaves contained elongated cells running parallel to the veins. Consequently the sap passing up the leaf stalk and into the leaves moved more readily along these fibrovascular bundles, having fewer cell walls to traverse. It was almost like going along a road instead of across country. The fibrovascular bundles then act as pipes conveying the sap, as it is clearly more economical that they should go straight to their destination rather than wind in a curve. As the sap passes more freely along the veins, the leaf also grows there more rapidly, which seems to explain the common lobed form of leaf with a vein running to the point of each lobe. Sir John Lubbock, with reference to some criticism on his views with reference to the relation between the size of leaves and the diameter of the stem, entered into certain particulars, especially with reference to conifers, pointing out that though the spruce fir, for instance, had shorter leaves than the Scotch fir, while the stem was as thick or thicker, yet the leaves remained on much longer—say seven or eight years, instead of two or three. He also discussed various other interesting problems presented by leaves, for instance, the probable reason for the larch having deciduous leaves, and for the presence of two kinds of leaves on certain cypresses and other trees.

## TIME REQUIRED TO DIGEST DIFFERENT FOODS.

IN a recent number of the *Monitor de la Salud* the results of some experiments lately made by E. Jessen on the time required for the digestion of certain kinds of foods are given. The stomach of the person on whom the experiments were made was emptied by means of a pump; 100 grammes, equal to 1,544 grains, or about 2⅔oz., of meat, finely chopped and mixed with three times the quantity of water, were introduced. The experiment was considered ended when the matter, on removal by the pump, was found to contain no muscular fibre.

It will be remembered that the gramme weighs nearly 15½ grains, and the cubic centigramme is equal to 1 gramme. The 2⅔oz. of meat were therefore mixed with nearly 8oz. of water, before being introduced into the stomach.

The results were as follows:—

| | | |
|---|---|---|
| Beef, raw, and finely chopped . | 2 | hours |
| „ half cooked ............ | 2½ | „ |
| „ well cooked ............ | 3 | „ |
| „ slightly roasted ........ | 3 | „ |
| „ well roasted ............ | 4 | „ |
| Mutton, raw .................. | 2 | „ |
| Veal ........................ | 2½ | „ |
| Pork ........................ | 3 | „ |

The digestibility of milk was examined in the same way. The quantity used was regulated so that the nitrogen should be the same as in the 100 grammes of beef.

| | | | |
|---|---|---|---|
| 602 cubic centimetres, nearly 16oz., of cow's milk, not boiled, required...... | | 3½ | hours |
| 602 cubic centimetres, boiled .......... | | 4 | „ |
| 602 „ „ | sour ............ | 3½ | „ |
| 675 „ „ | skimmed ........ | 3½ | „ |
| 656 „ „ | goat's milk, not boiled........ | 3½ | „ |

## MILLING TAPER WORK.*

HAVING had some experience at trying to make things *perfectly round*, I have some appreciation of the difficulty and expense connected with the process, and would hardly recommend such work to be used for keys, especially since they would be no better than ordinary round wire. I have used pieces of steel wire, cutting it into lengths a little less than the thickness of the cutters. This makes a half-round groove in the arbor, and the same in the cutter, and the advantages are that the distance-washers need not be made to go over the key, but can be left as they come from the key, and there being no key permanently fitted into the arbor, it is much less liable to be sprung out of truth; and there being no square corners in the key-way of the cutter, there is much less liability of starting a crack there in hardening; and, finally, the whole arrangement is cheaper, neater, and more convenient to use than square keys permanently fitted to the arbor in the usual way.

Some time ago, there appeared in this paper a drawing and description of a dog, for use with the Brown and Sharpe Universal Milling Machine, contributed, if I remember rightly, by a foreman of the Morse Twist Drill and Machine Company's Works. This dog was especially designed for use in milling taper work, and was supposed to adapt itself to any and all variations of angle between the centre line of the work and that of the dividing head spindle without cramping, and it was claimed for it that it did away with the only objection to the Brown and Sharpe machine. I believed all that was claimed in its behalf until I commenced to examine it closely, with a view to making one, when I dis-

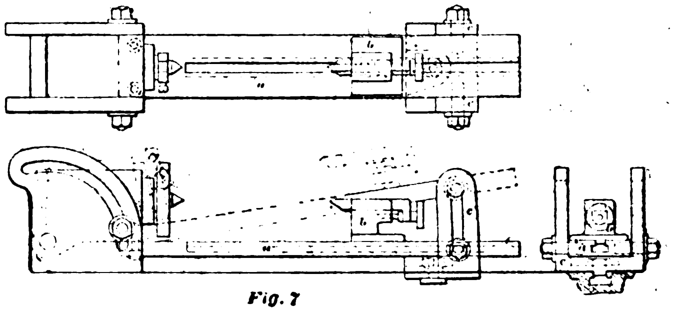

Fig. 7

covered that it only overcame one-half of the cramping difficulty, and that in order to make a truly universal dog it would have to be capable of several additional movements. Several of my mechanical friends became interested in the problem of devising one, and the fruits of our labours are represented by Figs. 1, 2, and 3, one of them being designed by a well-known M. E. They are all of them truly universal; that is to say, they cannot be cramped by any angle which comes within the limit of their motion. I trust they will readily be understood from the drawings; and it will be seen that they all require good workmanship in their construction to make them satisfactory.

Fig. 1, perhaps, needs no explanation: it seems to be capable of a good many motions, but, upon trial, none of them will be found unnecessary. It is a modification of the familiar universal joint.

In Fig 2 the pieces *b* and *c*, when the dog is in use, have a spiral oscillating motion in the pieces *a* and *d*, besides which use will be found for the joint between *b* and *c*.

In Fig. 3 the piece marked *b* has a ball upon its extremity, which is capable of motion of most any kind in the fork of the piece *a*. They all have their friends, some prefering one kind and some another, and the reader can take his choice.

Now, although any one of the above three breeds of dogs will be found to work very satisfactorily, so far as freedom from cramping in any position is concerned, yet I do not think they do away with the only objection to the Brown and Sharpe machine, because one objection consists in the necessity for any such dogs. And now, if, by presenting these dogs, I have conferred any benefit upon the fraternity of toolmakers, I can, perhaps, confer a greater benefit by showing how they may be dispensed with, and a common cur made to answer for all kinds of work.

No matter what kind of dog is used for holding taper work upon centres while being milled, if the centres must be placed out of line with each other, as in Fig. 4, in order to get the required taper, the accuracy of the divisions or indexing is entirely vitiated.

This is especially noticeable and annoying when a reamer such as is shown in Fig. 5, is to milled with continuous cuts or flutes from the small end to the shank *a*. On a piece of this kind it is necessary to depress one centre while milling the taper part; then when the centres are restored to the normal position for continuing the flutes over the straight portion, it will be found that only two of them will correspond at all, these two having been milled when the tail of the dog was in a vertical line above and beneath the centres.

Of course the others can be made to match, but this involves considerable trouble, and after it is done they will not be evenly spaced. The milling of a taper piece of square section would be almost an impossibility under such circumstances. By taking pains to have the dog in the proper position, as indicated above, two sides of the section might be made parallel with each other; but the other two would be neither parallel with each other nor at right angles to the first two, and the section, instead of being a square, would be what the geometricians would call a trapezoid.

A device for overcoming this difficulty is in use to some extent, and consists essentially of an adjustable tail block, or centre, in connection with the ordinary elevating head, something as shown at Fig. 6.

This is ingenious, and may be said to overcome the difficulty, inasmuch as it can be said that by its use it is possible to correctly index taper work. But the centres having to be adjusted separately, one after the other, it is exceedingly difficult to secure the precise adjustment necessary to do a good piece of work; indeed, it is almost what has been called a "corrugated impossibility." Taking the case of taper reamers, for instance: if the proper angle of elevation for the centres bore any fixed relation to the taper of the reamers and was computable, matters would be much simplified. But this is not the case, the angle at which the centres must be set depending upon the pitch of the teeth of the reamer and the shape of the cutter used in milling them, as well as upon the taper of the reamer, so that calculations are impracticable.

This makes it necessary to "cut and try" a process which, with a device in which the centres are capable of movement independent of each other, is anything but economical or pacifying.

I therefore submit the plan shown in Fig. 7, which is an attachment that may be adapted to any machine having an elevating head.

In this device the centres are perforce kept always in line with each other, consequently it is very little trouble to adjust, and it will produce taper work as accurately indexed as straight work can be. When used upon the Brown and Sharpe machine, it enables true spirals to be cut upon taper work, with the well known advantages of holding the work upon centres at the same time. It will also be found useful for bevel gearing within certain limits.

The piece *a* is a sort of supplementary table to the machine, which is attached to the elevating head by two screws as shown. Upon this is mounted the small tail block *b*, and its outer end is supported by the slotted arc *c*, which is secured to the table of the machine by the bolt shown.

It will be found easy to put on and remove from the machine, and obviates the necessity for any fancy breeds of dogs.

# DETERMINATION OF MIXTURES OF MILK-SUGAR AND CANE-SUGAR.

MIXTURES of milk-sugar and cane-sugar, such as are found in condensed milk, offer great difficulties to the analyst. These are such that usually only the milk-sugar is determined, the other being taken by difference. Messrs. A. W. Stokes, F.C.S., and R. Bodmer, F.C.S., describe in this month's number of *The Analyst*, a simple, rapid, and exact means of estimating both sugars volumetrically. They use an ammoniated cupric sulphate solution. Into a boiling measured quantity of this the diluted milk or mixed sugar solution is run from a burette till the blue colour disappears. This determines the milk-sugar. Another part of the milk solution is boiled with 2 per cent. of citric acid for ten minutes. The citric acid inverts the cane-sugar but does not affect the milk-sugar. This solution after neutralisation is titrated as in the former case. Thus the milk-sugar is determined. Results of various known mixtures are given and complete analyses of milks. A table is appended of the values of a quantity of the blue liquid (Pavy's fluid) in percentages of glucose, cane-sugar, and milk-sugar, so that calculation of results may be avoided. The advantages claimed are the sharpness of the end of the reaction, the ease and certainty with which all ordinary operators may rapidly attain the same exact results.

# BLEACHING OSTRICH FEATHERS.

THE following directions for bleaching ostrich feathers, though given on the commercial scale, may be found useful and suggestive:—Wash the feathers with Castile or curd soap and rinse thoroughly with lukewarm water in order to remove all the grease and soap which may stick to the flue; then soak in a bath composed of 1 gallon of ammonia (20° Be.) to every 8 gallons of plain water for about 8 to 10 hours. Take the feathers out of this bath, and squeeze out the excess of ammonia water which is in the flue. Put them in a bath composed of 5 gallons of peroxide of hydrogen, with the addition of 12 to 16oz. of liquor of ammonia; let it work slowly, stirring feathers from time to time, for about 6 hours; after 6 hours' working, put feathers on one side of the bath and add 5 gallons of peroxide of hydrogen and 3 to 4oz. of liquor of ammonia. Stir the bath well, so as to insure the mixture of the peroxide with the ammonia. Then let the bath work for 9 to 12 hours more, after that time add again 2 or 3oz. of ammonia. The peroxide will work for 12 hours more, until it gets exhausted, which may be ascertained by the following process:—Take a small quantity of the bath in a tumbler and throw in a few crystals of permanganate of potash. Should bubbles of gas appear, it is proof that the peroxide is working: if none appear, the peroxide is exhausted. The feathers have then to be rinsed three or four times in lukewarm water, and put into a second bath of peroxide of hydrogen, which is prepared as follows:—To 2½ gallons of peroxide of hydrogen add 2½ or 3 gallons of plain water and 8oz. of liquor of ammonia, and put in the feathers. Let the bath work so for 10 hours, and after that add again 2oz. of ammonia as before, and it will then work 12 hours more until it is exhausted.

It is said that this method will make white the darkest grey feathers—say, 10lb. of feathers, by using about 7 to 7½ gallons of peroxide. After the feathers have been taken out of the peroxide bath they must be rinsed thoroughly with lukewarm water two or three times, and after soaking them again in a soap solution for 6 to 8 hours, rinse them in lukewarm water, in order to remove all soap and dirt remaining in the flue.

# SCIENTIFIC SOCIETIES.

## ROYAL METEOROLOGICAL SOCIETY.

THE usual monthly meeting of this society was held on Wednesday evening, the 15th instant, at the Institution of Civil Engineers, 25, Great George-street, Westminster, Mr. R. H. Scott, F.R.S., president, in the chair, when the following papers were read:—

(1) "Report of Committee on Decrease of Water Supply." This Committee was appointed to take into consideration the question of the decrease of water in springs, streams, and rivers, and also the simultaneous rise of the flood-level in cultivated countries. As far as any inference can be drawn from the records collected by the Committee, it appears that the years 1820, 1821, 1824, 1835, 1838, 1845, 1847, 1850, 1854, 1855, 1858, 1859, 1864, 1865, 1871, 1874, 1875, and 1884 have been periods of marked low water. On the other hand, the years 1817, 1825, 1830, 1836, 1841, 1842, 1853, 1860, 1861, 1866, 1873, 1877, 1879, 1881, and 1883 have been periods when there has been exceptionally high water. In 1852 the water was very low in the early part of the year, while at the end of the year it was very high. In the intervening periods the water has been of moderate altitude. It does not appear from existing records that there is any diminution in the water supply of this country, and the large quantity of water which has been stored or has flowed off the ground between 1876 and 1884 is confirmatory of this view. There appear, however, to be periods when there is exceptionally low water, and these are almost immediately followed by periods of exceptionally high water. With reference to the increase of floods, it does not appear from the records that there is any great increase in the height to which the floods rise in this country. Whether or not the height to which floods have risen in recent years has been affected by river improvements and the greater facility with which floods can be got rid of, or whether there is a diminution in the quantity of water, are questions upon which the Committee have not at present sufficient information to speak positively.

(2) "Report of Committee on the Occurrences of the Helm Wind of Cross Fell, Cumberland, from 1871 to 1884." In response to a letter inserted in the Penrith newspapers, the Committee has received a number of communications bearing on the subject of the Helm Wind. With the view of ascertaining as far as possible the meteorological conditions which exist when the Helm Wind is blowing, all the recorded occurrences that have been received have been chronologically arranged. The first systematic record commences in 1871, and in this Report the Committee deals with all occurrences from that date to the end of 1884. Since that time more detailed records have been commenced at numerous stations in the locality at the instigation of the Royal Meteorological Society. Ninety-three instances of the Helm Wind were recorded from 1871 to 1884, the months with the greatest frequences being February, March, April, and November. On examining the Daily Weather Reports it was clearly seen that whenever the Helm Wind was blowing there was an easterly wind not only in the locality but generally over the entire country. As the Helm Wind seemed to occur so regularly with the easterly wind, the Committee further extended the inquiry with regard to the east wind. The daily weather charts were consequently examined for each day from January 1st, 1871, to December 31st, 1884, and every occurrence of east wind tabulated, the instances with general easterly conditions over the whole country being kept separate [from those instances in which the easterly wind was only partial, though of sufficient intensity to occasion the Helm Wind. This examination showed that, although the wind over the United Kingdom is generally easterly when the Helm occurs, yet the Helm by no means occurs whenever the wind is easterly. Indeed, this step in the inquiry has not at all tended to the elucidation of the phenomenon in question, for it frequently happens that the conditions are to all appearances precisely similar when the Helm is on, and yet no such occurrence has been recorded. This may in part be due to the occasional omission to record the Helm, although it cannot possibly be in the main attributable to such an omission; but it points to other conditions being necessary besides absolute agreement of wind direction and isobaric lines. Possibly the different hygrometric qualities of the air with the existing easterly winds may be an important factor in deciding whether or not the Helm will be formed, but it is not readily conceived why even in this case the Helm wind should not blow. It must, however, be borne in mind that the surface winds can only be examined, whilst those at a comparatively small elevation may be ultimately connected with the phenomenon. From the observations made prior to those started at the beginning of 1885, no idea can be formed of the behaviour of the upper currents even at the time of the occurrence of the Helm winds, far less with the occurrence of each east wind experienced. The society has, however, provided for the extension of the inquiry in this direction in the records which are now being collected, the observers supplying observations of the upper currents by means of the clouds, as well as the direction of the winds at the surface of the earth. As soon as a sufficient number of these observations have been received, the Committee hopes to present a further report, which will tend to explain the phenomenon of the Helm wind.

(3) "Results of Meteorological Observations made at Asuncion, Paraguay," by R. Strachan, F.R. Met. Soc.

## LIVERPOOL ASTRONOMICAL SOCIETY.

THE usual monthly meeting was held on April 13, the Rev. T. E. Espin, B.A. (president), in the chair. The Rev. J. H. Honeyburne, M.A., F.R.A.S., read a paper on "Evenings in Town with a Small Telescope." It was, he said, generally supposed that astronomical observation required an exceptionally good position besides every other convenience; but he had found a 3¼in. telescope in a little back yard in Liverpool quite sufficient to render the science a most delightful pursuit. He had noticed that members generally went in for a study and comparison of star magnitudes, or for an elaboration of mysterious hieroglyphics, supposed to represent the bottom of some ring-plain on the moon. No doubt this was all very important and interesting to the initiated; but he made no claim to originality, and would merely give an outline of the colours of some stars and the closeness or faintness of others. The tints of many of the stars were most lovely. β Cygni and δ Cephei he gave as examples; whilst the orange and blue of γ Persei fully entitled it to rank amongst the flowers of the sky.

Mr. T. G. Elger, F.R.A.S., hoped the important paper from Dr. Klein read at the last meeting would direct the attention of selenographers to the dark markings south of Copernicus. Since the publication of Schmidt's work he had carefully scrutinised this region, and on the 3rd November last had glimpsed two very minute black spots. These dusky features seemed to suggest an analogy to Mount Rossa, on the southern flank of Etna, which, according to Scrope, completely covered the surrounding country with a deposit of black sand during an eruption in 1669. Possibly something of this kind might now be occurring on the moon, and, if so, it would be amongst the smaller craters that we should look for changes due to present volcanic activity.

The President said he had lately, at Dr. Spitta's request, tested his new occulting eyepiece. It might briefly be described as a Ramsden eyepiece fitted with two pairs of movable shutters at the focus. Its work on double stars was excellent, especially when the companion happened to be faint and not too close, and he had by its aid discovered a new companion to 27 Hydræ. This was a wide and lovely pair *s. p.* α Hydræ, and was noted by the elder Herschel, though he did not think he had detected its triplicity. The pair was of 6·0 and 7·0 magnitude, but on examining them with this eyepiece a small *comes* of 11 mag. (Struve's scale) was at once seen about 8″ from the 7·0 mag. star, and at about 190°. Altogether, he thought the eyepiece supplied a want long felt, but, from the nature of the eyepiece, there was an unfortunate liability to "ghosts"; hence there was a danger of finding companions which had no existence.

Mr. J. E. Gore, F.R.A.S., contributed a series of observations of the remarkable variable star Mira Ceti. According to Argelander's formula, a maximum was due on January 28, but from his own observations this was not attained until Feb. 4, when he estimated it equal to α Ceti, or about 2·7 mag. The increase of light was at first very rapid, but it became afterwards much slower, and seemed to remain constant from Feb. 4 to Feb. 13. Mr. R. Wilding, hon. curator to Preston Observatory, announced his discovery of Tempel's comet. Its position on the 8th April was R.A. 12 hours and about 19° North dec. The nucleus appeared like a 13th mag. star surrounded by a nebulous disc.

The Secretary gave notice that he would bring forward for discussion at the next meeting a motion to enable members who reside at a distance to vote at the annual general meeting by proxy. Eleven gentlemen were elected members, and Dr. Copeland, of Dun Echt, was elected an associate of the society.

## LIVERPOOL SCIENCE STUDENTS' ASSOCIATION.

THIS Association has lately commenced a new session. At the annual meeting the officers were reappointed—president, Mr. A. Norman Tate, F.I.C.; vice-presidents, Mr. Henry A. Hill and Mr. Wm. Narramore; treasurer, Mr. John Edwards; and hon. secretaries, Mr. H. Leaton Edwards and Miss Helen Fryer. After the election, a paper, illustrated by limelight lantern views, was read by Mr. John Edwards on "A Visit to Rome." On Friday last there was a special meeting to make some alterations in the rules, and after that there was held the first ordinary meeting of the new session, when the president, Mr. Norman Tate, F.I.C., delivered a short introductory address, in which he strongly urged the members to be thoroughly systematic in their studies, not to be too superficial in their reading and observation, or to give attention to too many subjects, but rather to fix upon certain special subjects for inquiry, learn as far as possible all that is already known respecting them, test the facts and well weigh the opinions expressed concerning them, and then endeavour to further elucidate them by careful research. Mr. W. H. Read afterwards read a paper on "Astronomical Studies," in which he gave a comprehensive and interesting account of many astronomical discoveries, with an elaborate description of many of the bodies of the solar system, his remarks being illustrated by an excellent series of models, &c., prepared by himself, and by many diagrams shown by the limelight lantern of Mr. Knott. At the conclusion of the paper a brief discussion ensued, in which Messrs. Osmund, W. Jeffs, D. Clague, and M. Fitzpatrick took part, and the meeting concluded with a vote of thanks to Mr. Read for his paper.

## WESTERN MICROSCOPICAL CLUB.

ON Monday week this club met at the house of Mr. H. V. Tebbs, St. John's-gardens, Notting-hill, attracted by the subject of "Crystals under Polarised Light." The tables were loaded with apparatus for exhibiting the various phenomena connected with the "polarisation" of light, Mr. F. Crisp, LL.B., the hon. sec. of the Royal Microscopical Society, having kindly sent some exhibits from his ample stores. At the desire of the host, the Rev. Nicholas Brady, M.A., described the theory and method of polarisation, while Mr. Tebbs acted as demonstrator. The properties of crystals were described, especial reference being made to those in which the incident ray of light is split up. The methods of polarising by light incident at particular angles by bundles of plates, by Iceland spar, by tourmalines and herapathite, were all noticed. The changes produced in non-polarising substances by heat, strain, and electric currents, rendering them polar, were exhibited. Some of these were exceedingly beautiful. Large crystals of Iceland spar, cut at right angles to the different axes, showed the course of the ordinary and extraordinary rays. A very fine set of models, constructed by Mr. Brady, at the suggestion of Mr. Tebbs, exemplified the relation of the rays of light to the axes and surfaces of numerous crystalline forms. A cordial vote of thanks was presented to Mr. Brady for his valuable exposition, which was ordered to be printed.

Amongst the microscopical exhibits was a simple and inexpensive form of polariscope by Mr. Tebbs, in which the microscope was fitted with a plate of tourmaline below the eyepiece, the object being viewed on the stage without the objective; and some peculiar crystals deposited upon slips of glass from the smoke of coke, shown by Mr. E. Bartlett, L.D.S. Messrs. W. Gwinnell and B. B. Woodward exhibited a selection of the beautiful crystalline forms found in igneous and volcanic rocks. Mr. G. Karop brought out some beautiful effects in crystals by the use of Abbe's condenser and eyepiece analyser. Under the microscope of Mr. S. P. Moore, B.Sc., the diffraction bands were capitally shown in some polarised crystals of milk-sugar. Mr. E. M. Nelson contributed the exhibit of the evening—a polarised Podura scale magnified 2,500 diameters. But few exhibitors have managed to achieve this feat. Some crystals of erythrite (the colouring matter of lichens) glowed as perfect gems of colour under the microscope of the hon. sec., Mr. A. W. Stokes, F.C.S. Dr. Hart Vinen showed how beautiful the deadly crystals of nitrate of strychnia looked under polarised light.

At the next meeting of the club, on May 4, it is probable that Dr. Foulerton will demonstrate to the members a method of photographing microscopical objects. Mr. Tebbs announced that Mr. F. Crisp, LL.B., had invited the club to view at his house at a future meeting the effects produced by the electric polariscope.

According to a paper read before the Philosophical Society of Glasgow, by Mr. A. Williamson, the total area of the coalfields of China proper is about 400,000 square miles. Both the Shansi and Heenan coalfields are greater than that of the aggregate of the principal coal-producing countries of Europe, and in other districts of North China the coalfields are said to be seven times larger than all those of Great Britain. The coal is of various descriptions, and it is said that iron ores are found in all parts in close proximity to the coal.

Experiments are being made by the Government with a new locomotive torpedo steered by electricity from the shore. Very good results are said to have been obtained.

# SCIENTIFIC NEWS.

FROM Rear-Admiral Franklin, superintendent of the Naval Observatory, Washington, we have the official note of the observations of March last. First contact is given by Prof. A. Hall, using the great equatoreal, with aperture reduced to 4in., and a power of 383, as W. M. T., March 15, 23h. 57m. 6·9s. (probably one or two seconds late). Prof. Frisby, using the 9·6in. equatorial reduced to 4in., and a power of 90, made it 23h. 57m. 4·7s.; and Assistant-Astronomer Paul gives it as 23h. 57m. 7·5s., using an aperture of 5in., and power of 90; but does not think he could have observed it a second earlier on account of the state of the atmosphere. No observations of last contact could be made. The difference of R. A. of the second limbs of the moon and sun was observed by Lieut. Bowman on 11 wires of the east transit, and by Assistant-Astronomer Winlock on 9 wires of the transit circle, with the following results: B., Diff. 1m. 56·49s. ± ·028s.; W., 1m. 56·25 ± ·031s. Ninty-nine photographs of various stages of the eclipse were taken with the photo-heliographic apparatus.

Prof. Theodor von Oppolzer, in a note published in the *Monthly Notices* of March last says: "The words midnight and noon have a purely local character, like the words evening and morning. At a given instant it can be 0h. on the whole earth, if we have agreed to designate this given instant everywhere with this number; but there can be midnight only under one meridian at the same absolute instant; so the words midnight and noon are to be avoided when speaking of universal time." Prof. Von Oppolzer thinks that astronomers are more inclined to over than to under-estimate the trouble of a transition period; and that the uniformity of astronomical and civil reckoning is surely worth a little trouble at the beginning of the change.

Mr. Clement L. Wragge, in the course of his Mount Lofty meteorological observations, has discovered some extraordinary hygrometric conditions accompanying the northerly winds of an advancing barometric depression. Six observations from 9 a.m. to noon of Dec. 29 last, with the dry bulb giving a mean temperature of 78·8°, and the wet bulb a mean of 59·5°, disclosed the fact that the relative humidity of the atmosphere on Mount Lofty was 26. Similar observations made at the same time at Torrens Observatory gave means of 89° dry bulb, 63·5° wet bulb, and a relative humidity of only 18. It is only in such regions as the Soudan that similar hygrometric results would be obtained at such temperatures. Heavy rainfalls are sometimes registered in Australia. Mr. Wragge records for 24 hours ending Feb. 28 ·615in. at Torrens Observatory, and 1·1in., or 111 tons to the acre at Mount Lofty.

The Gresham lectures on Astronomy will be delivered on Tuesday, Wednesday, Thursday, and Friday next, by the Rev. E. Ledger. The lectures are given at Gresham College at six p.m.

The desirability of forming a British Textile Institute, somewhat on the model of the Iron and Steel Institute, has been mooted for some time, and in January last a preliminary meeting was held at which a committee was appointed to consider the various arguments *pro* and *con*. That committee has now reported in favour of the scheme, and has drawn up a constitution and rules as a basis upon which to found the institute. Forms of application for fellowship can be obtained from Mr. T. R. Ashenhurst, Technical College, Bradford, Yorkshire.

The Board of Trade return of railway accidents in 1884 is so far satisfactory that the numbers of persons killed and injured show a decrease on the previous year; but the number of persons who were killed from causes beyond their own control was 55 as compared with 22 of the previous year. Of these 31 were passengers, and 24 of them were killed in the Penistone disaster—singularly, the only passengers who were killed by the breaking of the 385 axles which failed during the year. Of these 223 were engine-axles and 24 tender-axles; the average mileage of 135 iron axles being 216,333, and of 59 steel axles 173,287 miles. There were 111 fractures of couplings, and the number of tires which gave way was 1,060, of which 1,005 were waggon tires, and 24 engine tires. Of the total number, 974 were made of iron and 86 of steel, 42 being fastened by Gibson's patent, 14 by Mansell's, and 5 by Beattie's. No life was lost through failure of a tire. There were 306 cases of broken rails.

Mr. Stretton's paper on the "Breaking of Locomotive Driving-Axles" is still being debated by the Leicester Branch of the Amalgamated Society of Railway Servants, the discussion having been adjourned to May 6.

Mr. Gugel, of the Central and South-Western Railroad of Georgia, is taking the reservoir of the Westinghouse-brake from under the footboard and placing it on the top of the boiler just behind the smoke-stack.

Dr. Dohrn's report on the zoological station at Naples states that it has been determined to add a physiological laboratory, and that the Italian Government has promised a grant of £4,000, £1,200 of which is to be paid this year.

The Royal Medals of the Royal Geographical Society will this year be awarded to Mr. Joseph Thomson and Mr. H. E. O'Neill—to the former for his well-known work in Africa, and to the latter for his thirteen journeys of exploration along the coast and in the interior of Mozambique. The Murchison Grant for 1885 will be awarded to the Pandit Kreshna for his four explorations made while attached to the Survey of India, and especially for his extensive and important journey in the interior of Tibet. The Back Grant goes to Mr. W. O. Hodkinson for his Australian explorations, and the Cuthbert Peek Grant to Mr. J. T. Last for his surveys and ethnological researches in the Southern Masai, Nguru, and other neighbouring countries.

The Institution of Mechanical Engineers will hold an ordinary general meeting on Thursday and Friday next, when amongst the papers to be read may be noted a description of the Maxim automatic machine gun, by Mr. Hiram S. Maxim, and a description of the Tripier Spherical Eccentric by M. Louis Poillon.

Thirty thousand "landlocked" salmon have been sent by the United States Government to the National Fish Culture Association.

The French Society for the Encouragement of National Industry have awarded the prize of £40, for the discovery of a useful new alloy, to M. Manhès. The alloy is prepared by mixing three parts of copper with one of manganese, and adding it in small quantities to the molten copper, after refining and just before casting. Copper so treated is said to be but slowly acted upon by sea-water.

# USEFUL AND SCIENTIFIC NOTES.

**Air-Tight Packages.**—According to the *American Druggist*, a German firm supplies chloride of lime packed in the following manner:—Quantities of quarter, half, and one kilo. are wrapped first in strong paper and sealed. The packet is then dipped for a moment in melted resin, which is as nearly cool as it can be to be fluid. This forms a perfectly air-tight varnish, and the parcel is lastly wrapped in a good paper and labelled. The idea is a good one, and may be adopted with advantage in packing photographic chemicals.

**Rugby Station.**—The work of building the new "island" railway station at Rugby, which is to cost some £70,000, and to be the biggest thing of its kind in Europe, continues to be rapidly pushed forward. Although it is expected that quite another year must elapse before the alterations are completed, yet it is hoped that the down side will be ready for use by about June next. The line has been widened 150ft. southwards, so as to give room for nine sets altogether of through metals, instead of four as now. For the greater safety at the junctions of the new Northampton line of the Stamford branch important works, presenting considerable engineering difficulties, have been effected. The traffic will be regulated by large signal boxes at each end of the platform, that at the south end having 180 levers.—*Engineer*.

**Grammatical Terminology.**—The Geneva Société pour le Progrès des Etudes offers a prize of 400 francs for the best memoir on a uniform system of grammatical terminology, applicable in the first place to the methodical study of the French language, and incidentally to the other languages studied in the cantonal schools of Geneva. The essays are to comprise a critical examination of the grammatical terms now in use, with the reasons in each case for retaining or rejecting them, and a complete list of the terms recommended for adoption, with their definitions and the words to which they correspond in the received system.

# LETTERS TO THE EDITOR.

*[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]*

*All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

*All Cheques and Post-office Orders to be made payable to* J. PASSMORE EDWARDS.

⁂ *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

> "I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks a vice from whence great inconveniences derive their original."
> —*Montaigne's Essays.*

## ERRATUM — THE SEASONS — LUNAR GLACIATION — CURIOUS OPTICAL EFFECT — ORRERY OR PLANETARIUM — THE "MONTHLY NOTICES" OF THE ROYAL ASTRONOMICAL SOCIETY—THE NEW TIME—"MAZZAROTH" AND THE MAGI—LENGTH OF FOCUS OF AN ACHROMATIC OBJECT GLASS — COLONEL DRAYSON'S "GLACIAL EPOCH."

[24136.]—I NOTICE a slight misprint in letter 24061, on p. 121, where, in paragraph two, "a whole wall" appears where I wrote a *white* wall.

There is a very obvious astronomical reason for the arrangement of the seasons in the form assailed by "Devoniensis" in letter 24070 (p. 124)—viz., that on March 20th the sun was on the Equator in his passage towards the Summer Solstice, or highest point above it, which he will attain on June 21st. After this his path tends downwards again, and on September 22nd he recrosses the Equator *en route* for the Winter Solstice, which he reaches on December 21st. Hence it will be seen that at the dates specified he occupies four perfectly well-defined points in his orbit. As for Midsummer and Christmas being "the middle or height of their respective seasons," I can scarcely imagine that many Englishmen will be found to endorse the views of your correspondent. Notoriously the greatest heat—or middle of summer—never occurs in June in this country. We get the very greatest heat towards the end of July or the beginning of August. So again with the greatest cold. I cannot recall an instance of Christmas day being the coldest day in the year. In this matter the mediæval couplet is scientifically accurate:

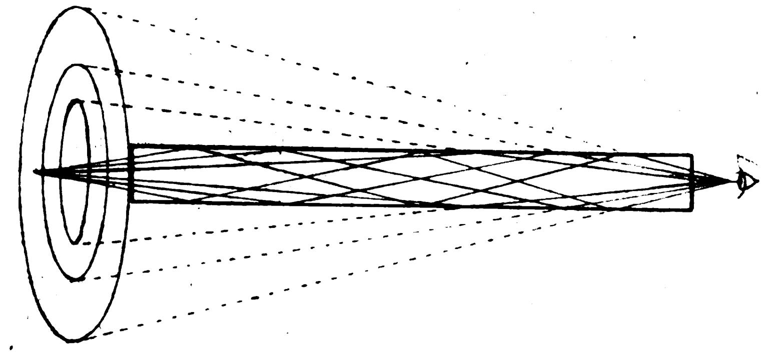
As the days lengthen,
So does the cold strengthen.

As for the etymology of the words used to describe the seasons, Spring comes from the old Saxon word meaning to sprout, or shoot forth: Summer is also Saxon; Autumn is the Latin *Autumnus*; Winter is Saxon. Our forefathers used to call December "Winter-monat," i.e., winter cometh."

May I ask Mr. Peal, in connection with letter 24082 (p. 126), if we are to understand that the "slow decline of . . . . atmosphere" took place unequally over the moon's surface; in other words, that it remained over the region of his equatorial seas, after it had disappeared from other parts of the lunar world? Because, if not, I do not see how his explanation quite meets my difficulty; for I quite fail to understand how an atmosphere could exist, so to speak, in patches round a globe? I ask purely for information. Mr. Peal must not imagine that I have discarded his theory as an absolutely untenable one, because, after due consideration, I do not feel justified in proceeding to that length. It does, undoubtedly, explain some of the visible lunar phenomena very neatly; but I still see considerable difficulties with regard to others.

What Mr. Culley (letter 24087, p. 127) saw in his gun-barrel was, I suspect, not a diffraction phenomenon at all, but one having its origin in multiplied reflections from the polished cylindrical interior. The rough sketch on next page will show what I mean. In it the course of the rays is traced from the source of light, assumed to be pretty near the muzzle, to the eye at the breech end.

I think that "Planetarium" (query 56353), p. 136), will find what he wants in Ferguson's books; but I have none of them at the place whence I write. If he lives in London, he should go to one of the second-hand scientific booksellers. Or he will find the numbers of the wheels for giving the relative motions of the various members of the Solar System in the article "Orrery," in the *Penny Cyclopædia*.



The letter (24105) of "Amateur Astronomer" on p. 146 comes particularly *apropos* of a discussion which (according to your report on p. 143) took place at the meeting of the Royal Astronomical Society on the 10th inst. As I am in entire ignorance as to the identity of your correspondent, I have no means of knowing whether he receives the *Monthly Notices* as a Fellow of the R. A. S., or as a purchaser of them. If in the latter capacity, he certainly has especially good grounds for his complaint. The cause, however, is not far to seek. Just so long as an almost purely Professional Council is allowed, year after year, to re-elect itself, just so long will its members and their friends be permitted to empty the contents of their observatory notebooks bodily into the columns of the *Notices*. It is not pretended for an instant that anybody will ever read—or, in fact, look at — such mere heaps of figures as those of which the "Amateur Astronomer" righteously complains. Whatever Professor Adams may say, I cannot but regard it as discreditable to the editing of our *Monthly Notices* that they should have been detained for such a paper as that which concludes the current number. It is simply ridiculous that the Country Fellows of the society should have been deprived of their right to receive them prior to the meeting, in order that this huge mass of figures should be read for the press: for the simple reason that they are of no *immediate* interest whatever, and would have been in ample time had they appeared in the supplementary number at the close of the session. The paper containing them certainly has the merit of being, in the legitimate sense of the word, an original communication; but I never remember one that would have kept better. Not that purely numerical tabular matter is necessarily devoid of either immediate or perennial interest, as is well illustrated by a communication by Mr. Stone on pp. 102 *et seq.* of Vol. XLIII. of the *Monthly Notices*. In fact, speaking impartially, I have little hesitation in saying that the papers of Mr. Stone, Professor Pritchard, and Mr. Downing in our *Proceedings* are worth the whole of the rest of those of their professional colleagues put together. A firm editorial hand would cure some of the evils complained of. The ruthless excision of such details as those of the runs of screws of particular micrometers, and an intimation to authors that if they were such very important people that they could not condescend to correct the proofs of their communications in time, they would be postponed until some future number, would introduce an immediate and manifest change for the better.

I am certainly in agreement with Mr. Hopkins (letter 24134, p. 151) as to the expediency of the adoption of the new time. Its initial inconvenience would be the veriest "nine days' wonder," and when once people got into the way of reckoning straight through the 24 hours (as they would in the course of a week or two), they would assuredly never dream of returning to the present unphilosophical mode of dividing the day. To the astronomer who has always adopted this notation in his own observatory, its adaptation to civil life would, of course, come as naturally as possible. I must admit that I am one of those people who are confused by railway timetables, as now arranged. Calculating as I do, every day of my life, and familiar with logarithms and mathematical tables generally as I am with the morning newspapers, I candidly confess that "Bradshaw" is too much for me. Stress has been laid on the chronological confusion which the commencement of the astronomical, equally with the civil, day at midnight would involve. But anyone who will study what was written in 1752, when 11 whole days were dropped out by Statute after September 2nd, will see what vaticinations were then uttered as to the utter derangement of all chronology whatever which must inevitably supervene on the change; and, in the light of subsequent events, be able to estimate the outcry at its true value.

If Mr. Arkwright wants to peruse a mass of wild and fanatical guesswork, destitute of any *scientific* value whatever, by all means let him get Miss Rolleston's "Testimony of the Stars," or "Mazzaroth," or whatever the stuff is called, as recommended by Mr. Mee in reply 56309, on p. 154.

In reply to "Perciverance" (sic) (query 56369, p. 156), I would never myself have the focal length of an achromatic cut down to less than one-fourteenth of the effective aperture of the object-glass. Obviously my querist is right in his proportions between the angular subtenses of the field of the same eyepiece when employed with objectives of varying foci. For example: suppose that the diameter of the diaphragm of our eyepiece were exactly 0·5in., then with a 60in. object-glass it would subtend an angle of 28′ 39″, and with an objective of 90in. in focal length an angle of 19′ 6″.

Mr. Richards (query 56380, p. 156) may well say, "But that 'if' is the difficulty." Mathematicians pay exactly the same amount of deference to Colonel Draysen's vagaries anent the centre of the earth's precessional motion, that they do the allegations of the late Mister "Parallax," concerning our world being a plane; or to the assertion of "Zadkiel Tao Tze," that the distance between the centres of the Earth and Sun is exactly 365,006 miles, neither more nor less!

**A Fellow of the Royal Astronomical Society.**

---

## DOUBLE STARS—θ AURIGÆ (O. Σ. 545).

[24137.]—In compliance with a request from Mr. H. Sadler, I have examined this star on five nights with my 10¼in. With (refigured by Calver), and send a few particulars which may interest our correspondents. I can most fully corroborate Mr. Hunt (letter 24103) as to the difficulty of seeing Mr. Sadler's *comes* at 170° 50″, it has only been seen on one night, and was then noted as "excessively faint." The small star at 340° is held pretty steadily, and the star marked C by Burnham in his 1878 measures 292° 45″ is very plain. With regard to the close pair I rated the small star as 8·5 or 9 mag. (certainly not more), and it looks still smaller from its colour (to me very blue). A rough measure without clockwork on the 17th inst. gave P.A. 3° ± dist. 1·7″ ±. Will some of our observers using larger apertures look up τ Boötis (O. Σ. 270) and report thereon? I think O. Σ.'s *comes* must be considerably below 11·7 now. Two years ago it was easily visible with an 8¼in. With. This year I have not as yet been able to see it; but on the 18th a very small star was suspected at about 260° 45″, possibly an illusion.

Letchford House, Pinner. **K. J. Tarrant.**

---

## TRANSIT OF JUPITER'S IV. SATELLITE.

[24138.]—On the 18th I watched the transit of the IV. Satellite from the time it had been on the disc about 35 minutes to its egress. It appeared as a black dot, and quite as dark to all appearances as that of the shadow of Sat. III., which was also on the disc of the planet at the same time. Inst. 3¼ Wray, pr. 120. **T. R. Clapham.**

---

[24139.]—On the 18th inst. I had the good fortune to observe this curious phenomenon. On first turning my 6½in. reflector on Jupiter, I saw what I thought was the shadow of a satellite in transit. On referring to the ephemeris I found it was the IV. Satellite. It was on the northern equatorial belt, about half-way across the ball; its shadow was about 8″ s. f. Both satellite and shadow were intensely black. Buildings interfering with view of reflector, the satellite was watched to egress with a 3in. achro., power 100.

When the satellite had got about 4″ from the limb it began to get fainter, and I soon lost sight of it until egress. For some time after egress the satellite was very faint, and could only be seen with close attention. **C. L. Tweedale.**

Crawshawbooth, Lancashire.

---

[24140.]—This evening, at 7.20, on turning telescope on Jupiter, I saw the shadow of Satellite III., and on looking for IV. saw in its place a very dark brown dot (almost black). I saw a similar occurrence March 26, 1873, when observing with the late G. W. Roberts, F.R.A.S. There has been a considerable break in my astronomical studies, and I am thus not competent to express any opinion as to the frequency of dark transits of IV. Sat. in the interval between 1873 and 1885. As this is just about equal to the period of Jupiter, can this have anything to do with the question?

In 1873 I was using an 8in. Wray, power 325, and under exceptionally favourable atmospherical steadiness. This evening I have been using a 6½in. Calver mirror, power 135, 144, and 250; but my position is very unfavourable, as a high hill to the south cuts off fully 15° of my view, and as the hillside becomes very hot in sunshine, radiation goes on for a very considerable time after sunset, and spoils definition. Thus, on returning to the observatory at 10 o'clock, the definition was very bad; but in moments of approximate steadiness I felt sure the satellite did not show as a perfectly circular dot. It was a little elongated. Shall be glad to hear if any other reader of "E. M." saw this somewhat rare phenomenon.

I should like to ask any telescopists who have used Brashear's silvering process for specula how they vary the quantity of reducing solution for varying temperature? Also if a paraffin-coated vessel will give a thicker film on speculum than if the silvering vessel were of ordinary glazed crockeryware, as I have found a heavy deposit of silver in the latter?

C. L. Tweedale (56368) had better be careful, as the model ventilator he saw is undoubtedly a patent. If he refers to the *Building News* he will probably find the ventilator advertised.

Ilkley, April 18. **Allan E. Kershaw.**

## THE DIAMETER OF MARS—AND CONCERNING ITS SATELLITES.

[24141.]—What is the real diameter of the planet Mars? I ask for information, because the textbooks are at loggerheads upon this interesting point. Taking down a few books at random from the shelves, here are some of the values assigned to it by various authors:—

| Miles | | Page |
|---|---|---|
| 3976 | Arago's "Popular Astronomy," Vol. II. | 472 |
| 4000 ± | Chambers' "Descriptive Astronomy," | 97 |
| 4070 | Proctor's "Saturn," .......................... | 219 |
| 4100 | Mitchel's "Stellar Worlds,".................. | 129 |
| 4184 | Beckett's "Astronomy Without Mathematics," .......................................... | 213 |
| 4200 ± | Lynn's "Celestial Motions,"................ | 14 |
| 4210 | Webb's "Celestial Objects," ............ | 140 |
| 4300 | Dunkin's "Heavens and the Earth,"... | 168 |
| 4363 | Guillemin's "Heavens," .................... | 178 |
| 4500 | Loomis' "Treatise on Astronomy," ... | 222 |
| 4546 | Herschel's "Outlines of Astronomy," | 730 |
| 4920 | Plummer's "Astronomy," ............... | 115 |
| 5000 ± | Proctor's "Other Worlds than Ours," | 87 |

Showing a difference between the extremes of more than 1,000 miles in the diameter of this small planet, and a very large fraction indeed of its total diameter. And yet several of the authorities quoted profess to give the value to a single mile! Surely such large discrepancies ought not to exist in works dealing with an exact science like astronomy.

Turning now to the satellites. In that remarkably veracious book "Gulliver's Travels" (Voyage to Laputa), occurs the following passage: "They have likewise discovered two lesser stars, or satellites, which revolve about Mars; whereof the innermost is distant from the centre of the primary planet exactly three of his diameters, and the outermost, five; the former revolves in the space of ten hours, and the latter in twenty-one and a half, so that the squares of their periodical times are very nearly in the same proportion as the cubes of their distance from the centre of Mars." Assuming the diameter of Mars as 4,200 miles, Dean Swift's hypothetical satellites would stand—

| | Distance. | Period. |
|---|---|---|
| Inner........ | 12,600 miles | 10 hours. |
| Outer........ | 21,000 ,, | ·21·5 ,, |

whilst the real ones are—

| | | | |
|---|---|---|---|
| Inner.... | 6,000 miles | 7h.39m. | (Phobos). |
| Outer.... | 15,000 ,, | 30h.18m. | (Deimos). |

Both sets satisfying Kepler's third law — the former giving the ratio 4·6, and the latter 15·6, between the respective cubed distances and squared periods. Looking at the state of astronomy in those days, it seems a pretty shrewd guess by the witty dean in 1727 of what was not discovered until 1877—150 years afterwards. **W. S. Franks.**

## ALARUM CLOCKS ADAPTED TO THE USE OF EXPERIMENTERS AND OTHERS.

[24142.]—In reply to "Abacus" (let. 24099), respecting the use of alarum clocks for giving one stroke upon a bell at given interval of time, the idea is a very old one.

Clocks with the verge escapement were used in connection with the work of astronomers in their observatories upwards of 60 years now passed and gone. The plan was a very simple one. A pin was fixed on the contrate-wheel, a slot being cut in the pillar-plate, from which another pin, made of an angular shape, protruded, planted at such a distance that the pin in the contrate-wheel began to lift a lever at the 45th second, which immediately discharged itself at the 60th second, and struck a good smart blow upon a bell, thus giving warning to the astronomer at the expiration of every minute.

Many years since I made a chronometer for a celebrated astronomer with a more elaborate attachment, which consisted of a pallet something after the shape of a pallet, to a duplex escapement. This was nicely fitted on to the fourth wheel or seconds pivot, the pallet lifting a nicely-balanced gold lever, which was brought back to its place by a delicate spring, not much stronger than the locking-spring of the chronometer; this lever lifting the tail of a hammer, which fell at the 60th second upon a very beautiful spring, or gong, fixed under the dial of the chronometer, which gave a very distinct blow at every revolution of the fourth wheel or at every minute.

An appliance, something similar to this, could be attached to the third wheel, which revolves twice in fifteen minutes; but then it would not always give a blow at the exact minute; the first blow would be at the 7½ minutes, or 7min. 30sec., and the second blow at the fifteenth minute. These applications can be made to any ordinary portable clock, without an additional train or winding up, similar to an alarum; but there would be some difficulty in constructing a train to denote a blow at egg-boiling time, or 3½ minutes, or any other irregular interval; but for the photographer or the astronomer, or for any observation consisting of any equal number of minutes, his attention is called exactly at the completion of every minute. My object in stating this to "Abacus" is to inform him that this method of denoting the exact expiration of every minute has been in operation for upwards of 60 years, and it is called the "journeyman clock" by astronomers and observers.

**W. B. Crisp,**
Author of the Prize Essay on "The Compensation Balance and its Adjustments."

---

## MICROSCOPE CONSTRUCTION.

[24143.]—It was with pleasure that I saw the promise of "Os" to supply the necessary instruction for making a micro. stand, for I have found much pleasure myself in similar work, and should have been glad to show how it was done without one *special* casting or piece of material; but then I am *insane*, for I ground all my own lenses, and *bought* none. I am also short of time, and should not do justice to a large task; but I will gladly supplement "Os's" papers on the brasswork by others on the glasswork. If "Os" will show how to make a stand as solid as his own mental condition, I will show also how to produce lenses as *free* from all aberrations as my mind may be judged full of them. **Rob. Crus.**

---

## "ENGINE-MAKING AT HOME."

[24144.]—As an old engineer myself, I have seen a great number of designs for the improvement of steam-engines, and if you think it of value to your readers I will briefly mention one or two of these as bearing on the subject in question. Now, from my experience of fixed steam-engines, whether large or small, if they were not fitted with either link motion or slip eccentrics, I should most decidedly use the form of guide for the piston-rod outlined at p. 533 of last volume, Fig. 4. The plan there shown is not exactly a practicable one, or one that could be used in practice on one point. But then the sketch in question is only intended to convey an idea, not a working detail. Now, I am not going to say anything on the question of appearance as regards the guide bars and motion work, as shown at Figs. 1 and 2, because if well made and properly proportioned the appearance is good, even showy. But how many amateur engineers can get such a job properly put together so that every part is true and square? Now, in my humble opinion, the fitting of parallel bar-guides is a very difficult matter, unless the maker is a practical engineer, and has efficient tools to do the work with. The number of the parts is much more than with a guide-shoe, whilst the bearing surfaces are rarely anything like the area that the guide-shoe plan gives.

If I was again making an engine for my own use, I should, in the first place, as we are on that point, use a guide-shoe, and I would undertake to get up the whole (for a small engine) without the use of a planing-machine. To make this easy, I should arrange the path of the guide-shoe, say, ½in. above the surface of the engine-bed; or make the guide itself to bolt on to the bed, thus allowing for lining up easier. Then I should most certainly have an overhanging cylinder—another advantage in finishing and use. I would desire to make it clear to "J. H.," or the writer of the articles in question, that I am not finding fault, or in any way attacking him or them, but that I state what my own views are on points of detail.

"X.," on page 128, reopens a question that I have many times had in mind—viz., that of heating a boiler by gas. I have not the early Vols. of the "E. M.," but I distinctly recollect a plan set out therein. It was to make the boiler of two half spheres of wrought iron, so that no stays were wanted, and the whole done on the anvil block. The edges were flanged out so that bolts held the two halves together. The sphere then was stood on a light casing with rings of gas underneath it. One peculiarity of it struck me at the time as not being so practical. It was the plan of partly shutting off the gas by a valve contracted by the steam. In other words, the pressure of the steam was made to force down or up a piston against a spring or resistance, and by a connection closing the gas supply partly. This is far better accomplished in the "Fontain" engine, where a corrugated tube is used for the same purpose. That the steam should regulate the source of heat is well enough; but there are practical difficulties with it, as when using a steam contracted gas cock. However, that is a problem we may yet solve.

"X." also mentions an oscillating cylinder for such small powers. Now perhaps I may, without trespassing on valuable space, just say that the class of model he mentions has no lead to the steam admission; hence the port is not wide open until mid-stroke, neither is the steam cut off until the very end of the stroke. Now such a thing with an engine of even ¼ h.p. would be very undesirable. To remedy this I have seen many plans, one successful one being a dodge to move the valve-face slightly either way, so that lead was given and an earlier cut-off. An ex-engineer in the Royal Navy, who subsequently started business as an engineer, brought to my notice a very good modification by placing the slide-valve in the bottom cover, the requisite lead and any cut-off being obtained by the oscillation of the cylinder and the action of a fixed link and block. This gave a very good result indeed. Still more recently in an engine I was invited to see in London the cylinder oscillated, but the slide-valve did not, being driven by an eccentric direct. The form in question was simple, and ran well. Contrary to my expectation, the flat surfaces did not leak steam or give trouble, as I should have supposed. Now I quite agree with "X." on the simplicity of an oscillating cylinder, and would willingly help him or others to practically solve this problem. That is to design a simple oscillator, but the valve to give a proper distribution of the steam. In my opinion it can be done with stationary valve-faces.

Having had experience with small high-speed motors, may I be allowed to say that I think there is not a question but that 1,000 revs. a minute could be got out of an engine with a cylinder 1¼in. by 3in. stroke. But the entire force of the steam would be wanted, or nearly so, to drive the engine. It must also be a special engine made for the speed, and with ports of unusual area. Then, again, if the engine be small, the boiler must be large, because a cylinder of that size and at that speed would want a great volume of steam, and the pressure kept up as well. So that I should be very strongly in favour of a moderate speed, say 200 revolutions a minute, with of course a larger cylinder than 1¼in., and longer proportional stroke, but the engine might be an oscillator, and of the simplest design possible.

A well-designed and made steam-engine in the shop of an amateur should be a thing of beauty and a joy for ever. I have had many engines, but few could ever come up to the horizontal of 2in. bore and 3in. stroke, made regardless of cost, and supplied with ample boiler power; the work it would do was wonderful, and nothing seemed (in reason) to be too much for it. On one point only it was originally troublesome, and that was the feed-pump from the speed was troublesome to start. But when it came into my hands I used a by-pass for the water and never had cause to grumble; the water was going into the boiler in a fine steady stream, thus not killing the steam, whilst at a moment's notice the full power of the pump was available if the steam began to blow off at the safety-valve. I trust more will be elicited on this subject. **Invicta.**

---

[24145.]—In a paper by Mr. Thornycroft, on "Torpedo Boats and Light Yachts," read before the Institution of Civil Engineers, in May, 1881, mention was made of a blowing-engine, which had "been worked at a speed of 1,700 revolutions per minute, or 56 strokes per second, without damage."

This was a reciprocating engine, with piston and connecting-rods, every part being properly balanced.

I forget the speed of the Tower spherical engine, but it is pretty high.

Can "J. H." give a sketch, illustrating Brotherhood's method of "moving his pistons by an eccentric," or refer me to one? (See letter on page 147.)

In all the drawings I have of these engines, the pistons have directly reciprocating connecting-rods and a crank.

The steam is admitted to all the three pistons on one side, the outer side of each being alternately connected to steam and exhaust.

The connecting-rods may, perhaps, be said to move the pistons, as, being single-acting, the steam only moves them outwards, and the inward stroke is made by the connecting-rod pulling the piston in again. **Glatton.**

---

## MINERAL-OIL LAMPS.

[24146.]—I should not again trespass on the courtesy of the Editor, or the patience of the readers of the English Mechanic, had not direct reference been made to me by two correspondents in this week's issue.

To Mr. P. Ward, I will only observe that in all my letters I carefully refrained from particularising any special lamp, as I desired to shun even the appearance of using the correspondence pages of this journal as an inexpensive advertisement medium. However, since Mr. Ward has mentioned the "Silber lamp," I cannot honestly permit his damaging statement, in reference to one lamp, to pass without recording my experience of many. I use (amongst others) six of these lamps, and though they have been in constant use for some years, and are lighted for sixteen consecutive hours in mid-winter, no explosion has ever taken place, nor has the carrying part of the opals ever, during those hours, been raised one degree in temperature, though they are freely carried about in a large house. Though far from being the best lamp, they are good, useful, and safely constructed, and in their cheap form have quite revolutionised the lamp trade, being at present the most popular lamp sold.

Colonel Shakespear says that I "ought to know that over-heating is caused by the metal wick-tube being in the oil," &c. I only reply that when he writes on a subject he ought to know more about it. Such long sheaths were only used in the old vegetable-oil lamps, but no well-made mineral oil lamp, raising oil by capillary attraction, has any such fitting, as it would simply prevent the lamp burning.

In initiating this correspondence, I had hoped some expert might have taken the subject up, and that I and other readers might have benefited by information thus imparted, as there is no subject more useful to the general public, and none so imperfectly understood. Perhaps my hopes may yet be realised; as it is, however, I will not further pursue it, as I may be informed, by some "well-instructed correspondent," of the demise of Her late lamented Majesty Queen Anne, and be expected to enter on a controversy on the subject.

**J. Hughes.**

---

## THE MUSICAL SCALE.

[24147.]—On p. 129, No. 1046, Mr. S. E. Hunt objects to my "method of arriving at the measures (of the scale) by a succession of perfect fifths as inaccurate, as no number of perfect fifths can exactly equal the number of octaves." Like Mr. Elphick's proof of the correctness of the harmonic scale, this objection applies equally to the scale advocated and to that objected to. The scale of equal temperament is the only one which will stand this test. When Mr. Hunt says that a comparison of the values given by me with those of the equal-tempered scale shows that in the former the errors (of the latter) are exaggerated, he simply begs the question and asumes as admitted what he desires to establish. But when he says "tune to his measures, and hear how they sound," he appeals to the only true test, the one which, having applied, I find conclusively supports my case. In its application, however, as in every testing experiment, proper precautions and conditions must be observed. The monochord is, perhaps, the best instrument to use; but care must be taken that in shortening the string to produce the different notes, its tension be not at the same time increased. Another condition is (and this is essential because the scale to be tested is simply melodic) that only one note at a time be sounded. Of course, one cannot do otherwise on a monochord; but still there is such a prejudice in some minds in favour of the idea that the pitch of a note must be regulated to form perfect harmony with some other note or notes sounded along with it, that this test is apt to be applied in substitution for that of simply listening to the single notes sounded in succession. If these conditions are fulfilled, it wil lbe found that upon a monochord, divided in accordance with the perfect-fifth plan througout, the natural scale may be played or a simple melody performed with the most correct intonation; while, if the harmonic divisions are used, the third, sixth, and seventh notes of the scale become decidedly flat. This flattening is especially noticeable in the third and seventh, because it makes the semitone intervals above these notes disagreeably wide. No doubt, when a tune is accompanied with chords of other notes than those of its own melody, it is best to employ notes having the harmonic values, because more pleasing harmony is thus obtained; and in this case the departure from correct intonation in the air is not noticed.

The violin, next to the human voice, has been considered to be the most perfect of musical instruments; in fact, that these two are alone capable of giving perfect intonation. But the four unstopped strings of the violin, when properly tuned, give at least four fixed notes at intervals of a perfect fifth apart. Now this tuning is inconsistent with the harmonic scale (or, rather, that scale is inconsistent with itself). The vibration ratio of the perfect fifth is $\frac{3}{2}$ (and in this the harmonic and melodic scale agree), therefore calling the vibration *rate* of the lowest or G string 12, that of the D string is 18, of the A string 27, and of the E string 40½. But according to the harmonic theory, E must also have a vibration rate, which is $\frac{5}{3}$ of that of the G immediately below it. This G (being the octave above the note of the open G string) has a relative rate of 24; $\frac{5}{3}$ of this only 40. Now will Mr. Hunt say to which of these two pitches, 40½ or 40, the E string ought to be tuned? They seem both to be required by the harmonic system. Shall we say that, as ordinarily tuned (E string 40½), the violin is not fitted for playing in the key of G?

The scale of equal temperament, as Mr. Hunt indicates, is nearer to the harmonic scale than is the melodic or natural one, and it allows of harmonic combinations which, if not perfect, are sufficiently near exactitude to satisfy ordinary musical ears, and not seriously to offend those of finer sensibility. This, no doubt, is one reason of its general adoption; but its chief advantages are that it simplifies the system of notes required for concerted music by restricting the number to 12 in the octave, and also gives the same limit to the number of digitals or claviers required in the organ, pianoforte, &c.

Joppa, April 13. **W. Hardie.**

---

## MUSICAL SCALE.

[24148.]—The question in dispute appears to hinge on the following: Is a major third to be made or not by taking $\frac{5}{4}$ or $\frac{81}{64}$ of a monochord to make it? I am quite alive to the fact that various series of fractions or ratios might be taken. Mr. H. has taken one, and with an appearance to differ from Nature's love to coincide with harmonics.

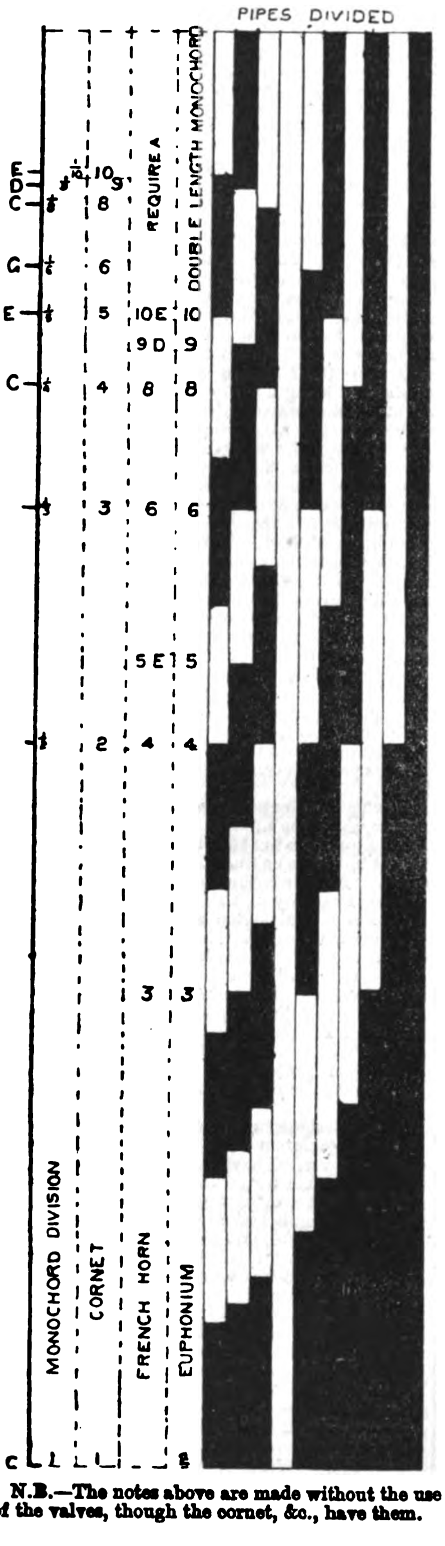
I will first take the over-blown pipes. Thus, a pipe having a certain size in *cross section* to a certain length, voiced properly, gives a full note (a one-wave tone); the same length pipe reduced in cross section by a little more pressure of wind would give the octave (a two-wave tone) most freely: still smaller, as a cornet, &c., you have great trouble to get the *one-wave tone*, if you do get it, that would depend on how much the tube had been reduced in the cross section, as all are not reduced alike; but it is rarely you can get what might really be called a note. In the French horn of the old kind, no valves, when long crooks are put on, the *two-wave note* is hard to get, even with very tender lipping; but the *three-wave tone* may be called its first division, then a four-wave, five, six, eight, nine, and ten waves follow.

In open pipes, at the end of every wave, we have what are called swells, in the centre of each wave what are called nodes; every open pipe or horn must have the swell at each end, if either divided by one or more waves; stop pipes divide in another manner, though in whole waves in them.

I herewith give a table as the best means to show what I mean; if W. H. will not accept it I cannot help that; but the thousands of readers of the "E. M." must judge—some may accept, others may not.

The fractions at the side give position to stop or bridge for certain pitches on the monochord to be tuned to C, the tenor C, and all the horns to be in C, though they are made in other keys; the pipes also tuned to C; the French horn and euphonium in their position, though they divide the same. I might hint at the wonderful number 7: it gives a sound, but not of use in harmony of music; in mathematics it is a most wonderful divisor.

Many writers on acoustics have given us divisions as I give, and as the question rests on the $\frac{5}{4}$ third or not in the table, we have four and five waves—C and E, and that divided by eight, nine and ten, C, D, and E. The table also shows how simple numbers in proportion can be used as fractions, and simply divides the monochord, pipes, or horns, and agrees with harmonics. Do we want to make them disagree? What for? Now if we take "W. H.'s" monochord, he also takes two numbers, or fractions, one for flats, the other for sharps (I do not agree with him how he has placed them), and to arrange for any key, like myself and others have taken the equal temperament, some might say, How does this affect the question? Let us test for a proof in another way, by the help of equal temperament. "W. H." puts his fifths all perfect ones; we will leave out his first fifth, the F to C; it won't affect the question, and start, as some pianoforte or organ tuners would do, what is called tenor C, tuned to a fork, then tune C to G above, now its octave G below, from this G to D above, from D to A, this A to its octave below, from this A to E, all in perfect fifths. Here we come to a test; by having a C E G on the perfect fifth principal, strike the chord. Does a tuner like this? I think not. He will say the *third is too sharp*—hardly bearable. This is the $\frac{9}{8} \times \frac{9}{8} = \frac{81}{64}$ third. To make the thirds more pleasant he makes the fifth slightly flatter. If done well, it will be the equal temperament. This third amounts to $\frac{51000}{40478}$, whereas the $\frac{5}{4}$, with the true fifth, which belongs to the harmonics, if struck as a chord, what ear can be offended at it? Its simple numbers, four, five, and six waves, repeat and repeat, whereas in the others would repeat but seldom, and only produce beats instead of a third tone, which would not mix pleasantly. A C of 128 and E of 160 waves would give a sub-harmonic 32 beats to the second, and with a fine ear can be heard as a sub-harmonic; a C and E, two or three octaves above, would give out a higher and stronger harmonic; if C and E a $\frac{81}{64}$ third we should have to chose those having 2048 and 2592 waves per second to give even the first recognised sub-harmonic, therefore beats or a shaking noise would be heard if lower thirds were used of $\frac{81}{64}$ kind.



N.B.—The notes above are made without the use of the valves, though the cornet, &c., have them.

"W. H." also says it's not a *fifth*, the B to F. Will he undertake to correct all those who write on "Thorough Bass," or show where our good composers of the past were wrong? They have shown us how to use this fifth, and call it a diminished, or an imperfect fifth. I know it is a discord, but it is used and resolved to a concord. I will not undertake to correct them.

I take this step to answer on account of the readers of the "E. M." Those who already know will excuse if I tell the "Old, old story." Those who live to learn, like myself—should I have given them any hints worth note, I shall feel thankful I have at least written for some one's good. I would ask every cornet or horn player of the "E. M." readers to test the table without the use of the valves. I have kept to the key, that no twisting or elastic arguments could call forward enlargement or side thrusts, as both readers and Editor might tire.

Before I close I will touch on the semitone, which makes up the fourth. Is not a $\frac{16}{15}$ more simple than the semitone fraction $\frac{256}{243}$? also $\frac{5}{4}$ for the third than $\frac{81}{64}$. In the table I have not the $\frac{16}{15}$; but that could have been shown if I had enlarged the table and divided the monochord, for 12 to 15 is as 4 is to 5, and 12 to 16 as 3 to 4; therefore the difference of a third and fourth.

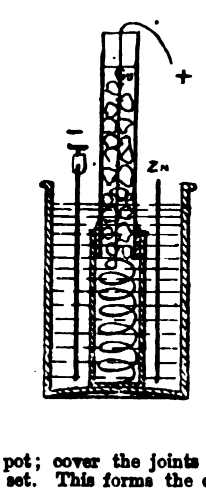
I will now conclude. I think I have not cut up and disagreed with harmonics, and what true lover of music would not feast on chords struck by them to his inmost soul's delight, and even now and again admire a diminished or imperfect fifth, that by contrast the harmony might be enriched, and thus gain rather than lose by there being more than one fifth, as well as more than one third, as the $\frac{5}{4}$ third, which is used.

New Cross, S.E. **W. H. Elphick.**

---

## IMPROVED DANIELL CELL.

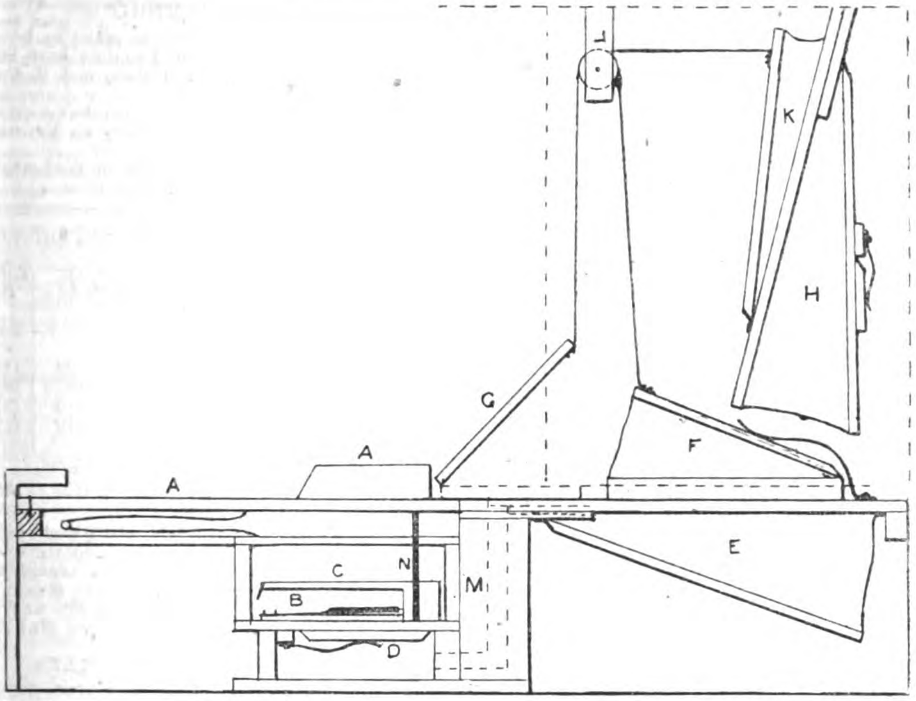
[24149.]—Hoping it will be interesting to some of your readers, I herewith send you a description of my new cell. All who have used the Daniell cell know what trouble there is to keep the copper solution out of the zinc division, because it always has a tendency to creep over the porous partition or pot, and so into the zinc sulphate. This arrangement which I am about to describe completely stops this action, and so adds to the life of the cell. The solutions still mix, but only by diffusion through the porous pot; this cannot be stopped by any means which we know of. In making up this cell, I take a porous pot 1in. shorter than the jar which forms the outside containing vessel, then take a piece of glass tube 4in. or 5in. long, and of a diameter slightly smaller than the inside of the porous pot, wind round one end of this a length of ¾in. tape until it fits the pot tightly; soak this end in melted wax and place it in



the porous pot; cover the joints with wax and allow it to set. This forms the cell to hold the copper solution. To form the negative pole, take a few yards of copper wire and wind it into a close spiral which just drops through the glass tube; leave a length of wire to form the outside connection. Bend a zinc plate to fit outer vessel, and the cell is complete. Charge in the usual way, and place a few crystals of sulphate of copper in the glass tube. It improves the cell to cork the glass tube, passing the wire through the centre of the cork. The solutions should be level with each other, and sufficiently high to cover the juncture of the glass tube with the porous pot. You will readily see that this form of cell makes it impossible for the copper sulphate to find its way into the zinc solution except by diffusion. This form of cell is well adapted for electric clockwork, and as I have seen many inquiring for a suitable battery for this purpose, I hope this will meet their wishes.

I inclose a rough sketch of the cell, which explains itself, if you think it worthy of publication.

**Clement H. Wragge.**



## SEPARATE PEDAL ORGANS FOR AMERICAN ORGANS OR HARMONIUMS.

[24150.]—Thinking that this subject may be interesting to the musical portion of your readers, I send rough sketch and brief description of a separate pedal organ, which can easily be attached or connected to an American organ or harmonium not affording the facilities for pedal practice at home. The pedal organ is contained in a frame not less than 6in. deep. The instrument, to which it is required to be connected, is placed over or on the back portion of the frame in which is situated the bellows, consisting of a large reservoir and two feeders. In reference to sketch, A A shows pedal board, B the reed, C the tube, D the pallet, E is the reservoir of pedal organ bellows, F is the feeder of same, H and K show reservoir and feeder of American organ bellows. The feeders of both instruments may be connected to the footboards by webbing attached in the usual way. G is the footboard of American organ. A separate roller, L, should be added, to pass the webbing over; that is connected to feeders of pedal organ bellows. N shows the plunger, which is actuated by the pedal. The dotted lines at M show how the air is conducted from windchamber to reservoir. The other dotted lines show position of side of American organ to which the pedal organ is connected. If the bellows of the latter is required to be worked by a separate blow-lever, with the bellows of the American organ, the mode of connecting the feeders will somewhat differ to that explained in sketch. The feeders of the pedal organ bellows may be connected to both footboards and separate blow-lever if desired. Munroe's pedal bass reeds are most suitable for the described arrangement, as it is constructed on the suction principle, with exhaust bellows. It is more convenient, and less trouble, to place the reeds in a tubeboard, with tubes spaced out to suit the compass of pedal board. The latter method does away with the inconveniences and complication of a radiating action, and is certainly more simple, and quite as effectual, as the other method. **G. Fryer.**

## TESTS FOR A 6½in. MIRROR.

[24151.]—If "Aleph" (letter 24102) would get Webb's "Celestial Objects for Common Telescopes," he would have no difficulty in finding plenty of tests for his mirror. He must not, however, flatter himself that ξ Ursæ Maj. is at all a test for a 4in. o.g.; I divide it easily with my 4in. Wray, power 160. Webb calls 52 Orionis an excellent test (for what aperture he does not say), but I divide it well with 250.

As comparative light tests, perhaps the following may be suggested:—

| | |
|---|---|
| ν Ursæ Maj. | 4, 12, – 7·8″ |
| ι Do. | 3·5, 13, – 12″ |
| θ Boötis | 4, 12, – 60″ |

The two 13th-mag. stars between $\varepsilon^1$ and $\varepsilon^2$ Lyræ.

As a test of separating power

| | |
|---|---|
| ξ Boötis | 3·5, 4·5, – 1″ |

These are all visible to the naked eye, and are now well placed for reflectors; but unless "Aleph" has a star map; I don't see how he is to identify them; and if he has a map, why request naked-eye tests, as almost any star can then be found if care be exercised, either by the finder or a very low power. I, of course, assume the absence of equatorial circles.

I saw ν Ursæ Maj. well, and the two debilissimæ in $\varepsilon^1$ and $\varepsilon^2$ Lyræ with difficulty (being low down) on the 6th inst., powers 160 and 290 respectively, though I am situated in the heart of the City. The others I have not yet examined.

London, April 18. **Beta.**

## A NEW METHOD OF FORMING CRYSTAL MODELS BY PLAITING.

[24152.]—I think it will be hardly necessary to define the models, which can be formed from the diagrams otherwise than by their names.

Fig. 10 gives the *Doubly Oblique Prism*, Fig. 11 the *acute rhombohedron*, Fig. 12 the *obtuse rhombohedron*, Fig. 13 the *Scalenohedron*, and Fig. 14 the *Double hexagonal pyramid*.

FIG. 10.

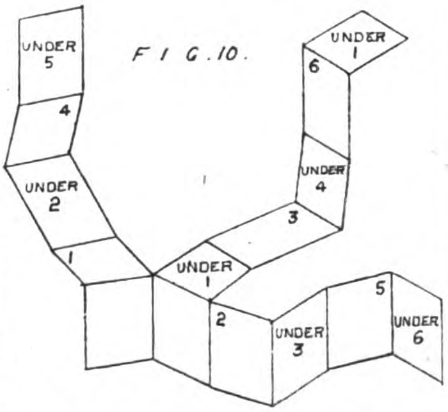


FIG. 11.

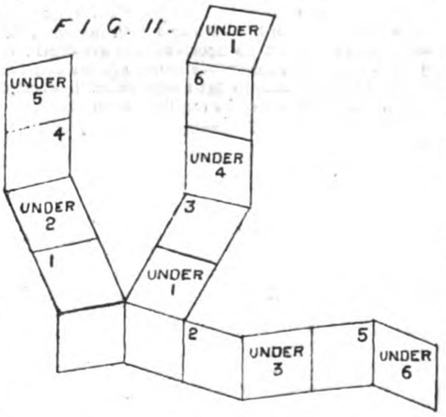
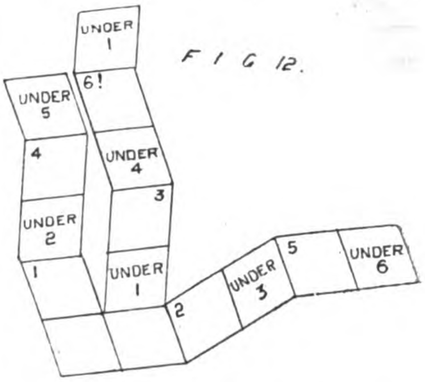


Many readers will be previously aware of the forms of these models, others will have little difficulty in plaiting from the figures; and if those who find any difficulty will send me a stamped envelope I shall be very happy to send them an explanation of their difficulties, and perhaps one of the models, from which they will get a better understanding of my meaning.

FIG 12.



Only one remark is, I think, really neeeded on the above-mentioned figures. In Fig. 12 the mark ! will be seen on the face marked 6. I put this there so as to mark the face which should be pulled, after the model is plaited, so as to undo it with the greatest ease.

FIG. 13.

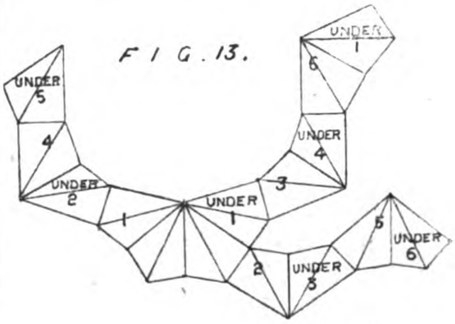


FIG. 14.

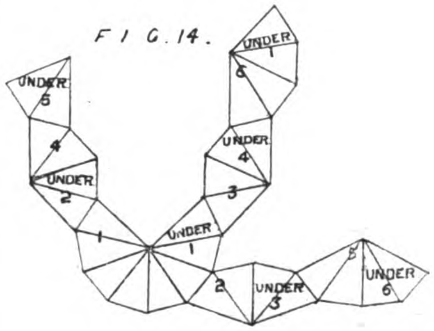

Errata.—In the heading of my first letter on this subject "crystals" should be crystal models; in the heading of my second letter "foming' should be forming. In my first letter I should have said that the best material for making the models is "glazed cambric pasted on white paper." In my second letter, in the formula for Fig. 7, "δ" should be S.

In the analytical table sent with my last letter, "scalenshedron" should be "scalenohedron," and "rectangular octohedron" should be "regular octohedron."

I quote from a letter I have just received from Mr. Gorham the following remarks:—"The models require *some* making to bring them home completely. You cannot make a model correctly by drawing it with compasses and ruler, but by making a plane of cardboard, and repeating it by tracing around it, and this in such a way that the proximity of the planes decreases from zero—say, from the two blank planes of a cube, which are to remain inside—to plane 6, which is to come outside, so that the two blanks and plane (1) and plane (under 1) are drawn as close as possible; plane (2) is a shade of a ghost of a line farther apart, but plane (under 2) is kept close; (3) is sensibly at a greater distance and (under 3) close; (4) is wider still, and so on. I find this is the only decent way of making a model after a trial of *some hundreds*."

Park House, Tonbridge. **E. A. Tindall.**

Comparison of Tides at Liverpool and Fleetwood for the Month of March, 1885.

| Date. | Calculation. | | Observation. | | Error. | Barometer | Wind. | Remarks. |
|---|---|---|---|---|---|---|---|---|
| | ft. | in. | ft. | in. | | | | |
| March 1 | 28 | 6 | 27 | 11 | − 7 | 30·1 | W.N.W. to E.S.E | Slight. |

| | 22 | 10 | 23 | 11 | +13 | 29·8 | S.W. | Strong to gale. |
| 27 | 23 | 9 | 24 | 4 | + 7 | 29·7 | W.S.W. | Strong to gale. |
| | 24 | 5 | 25 | 6 | +13 | 29·9 | N.W. | Very strong. |
| 28 | 25 | 7 | 25 | 0 | − 7 | 30·2 | W.S.W. | Fresh; sudden rise in bar. |
| | 25 | 11 | 25 | 9 | − 2 | 30·1 | W.S.W. | New depression approaching. |
| 29 | 26 | 10 | 27 | 4 | + 6 | 29·9 | N.W. to S.S.W. | Fresh to strong. |
| | 26 | 11 | 26 | 2 | − 9 | 30·0 | N. | Very strong. |
| 30 | 27 | 10 | 26 | 10 | −12 | 30·1 | S.S.E. to N.E. | Fresh. |
| | 27 | 8 | 27 | 8 | 0 | 30·3 | S. | Slight; bar. rising generally. |
| 31 | 28 | 0 | 27 | 7 | − 5 | 30·3 | N.E. to S.S.E. | Slight; anticyclone. |

## COMPARISONS OF TIDES.

[24153.]—The interest which attaches to the oscillations of the ocean as connected with the varying barometric conditions and the direction and steepness of the gradients of the atmosphere can only be appreciated by those who make the subject one of close observation and study, and who have the advantage of residing in localities where the tides are, if superimposed, of equal age and of extensive range. This is the case eminently on the Lancashire coast. During the last month, as is the case in March generally, the weather has been exceedingly unsettled; the fluctuations of the barometer have been very extreme, and the alternations of cyclone and anticyclone extraordinarily rapid. But a reference to the accompanying comparisons, which are drawn from simultaneous observations made at Liverpool and Fleetwood, will show how completely the sea-level is subservient to these changes, and with what amount of exactness their effects may be predicted. The "diurnal inequality" maintains its sway in spite of them all, and the law which regulates it is proved to be inexorable. As surely as the moon or "anti-moon" (i.e., the obverse attraction) is traversing from the southern to the northern hemisphere—from a region, in fact, where ocean predominates to a region in which there are only continents—so surely is the corresponding rise of tide due to the attraction greater than that of the following tide, and *vice versâ*. The month of March opened with strong winds, due to a large anticyclone, which was travelling from north to south. This was succeeded by cyclones of less area. From the 9th to the 23rd anticyclones prevailed almost continuously, and as these rotate in the direction of the hands of a watch, with barometer highest in the centre, they deluge us with cold airs from the north and east, and cause the prevailing low temperature, which is so generally objectionable. But the sea-level is thereby depressed, and each tide shows it; often the depression is in advance of the wind, though sometimes it lags behind it. A sudden shift in the motion of its centre seems to cause an equally sudden change of level, examples of which occur on the 24th and 26th instants. The accordance cannot be accidental or artificial; it is quite certain all such movements are submissively made in obedience to laws by which hydrostatic and pneumatic pressures regulate each other.

**James Pearson, M.A., F.R.A.S.**

Fleetwood, April 8.

## OLD LOCOMOTIVES.

[24154.]—Railway men who remember the opening of lines 55 years ago are few and far between, so it is always pleasing to hear from them. It is quite certain, from what Mr. Stretton and Mr. Read say (letter 24123, p. 150), that in 1830 there was an engine "Invicta" on the Whitstable line; but is it not strange that none of the locomotive books—Woods, Clarke, and others — say a word about either the line or the engine. Will Mr. Edw. P. Read kindly say how long the engine was at work, where she is now, who the line belongs to at the present day, and any other things he can tell us about the old rails and rolling stock?

**Anxious to Know.**

## NEW MIDLAND ENGINES.

[24155.]—Yes, sir, it is true, as asked in letter 24126, p. 150, that the big 1667 engines have less heating surface than the 800 class, and it does account for all lost time.

An engine that is short of steam is never a cheap working engine: she must be heavy on the coal heap.

Below I hand you a few figures about the heating surface of a few engines on the Midland—

| Number. | Date | Cylinder. | Stroke. | Wheels. | | Heating surface. | | |
|---|---|---|---|---|---|---|---|---|
| | | | | | | Of tubes. | Of firebox. | Total ft. |
| | | | | ft. | in | | | |
| 890 class. | 1871 | 17 | 24 | 6 | 8 | 1020 | 92 | 1112 |
| 800 rebuilt | 1877 | 18 | 26 | 6 | 8 | 1115 | 110 | 1225 |
| 1327 | 1877 | 18 | 26 | 7 | 0 | 1203 | 110 | 1313 |
| 1667 | 1884 | 19 | 26 | 7 | 0 | 1011 | 110 | 1121 |
| London and Brighton engine, Gladstone. | | | | | | | | |
| Gladstone | 1883 | 18½ | 26 | 6 | 6 | 1372 | 112½ | 1585 |

The figures tell their own tale, and I won't take up your room. Just look at the proportion of cylinder to heating surface: that is enough to account for all faults we hear of. There is not an engine on the line like the 800 class for fine work.

**An Old Locomotive Man.**

## LOCOMOTIVE DRIVING AXLES.

[24156.]—I entirely agree with your correspondent "Inquirer," p. 150, that the question of axles breaking should receive the careful attention of the railway contributors to the English Mechanic.

In your issue of 13th March, I gave a table, p. 34, which I hoped would form the subject of discussion, but it appears that it "has been passed over in silence."

The subject is certainly one of considerable difficulty, and further details and knowledge will be required before the subject is finally understood. "Inquirer" asks, "Is iron or steel the best material for crank-axles"? This is a very proper and a very natural question, but one that neither I nor any other engineer can correctly reply to in the present incomplete state of knowledge.

During the year 1883, 347 crank or driving axles failed; 173 were made of iron, and 74 of steel.

The average mileage of

171 iron axles = 213,719 miles;
72 steel axles = 199,471 miles.

The mileage of four axles being exceptional, it is not included in this average.

During the nine months ending 30th September, 1884, 152 crank or driving axles failed; 102 were of iron, and 50 of steel.

The average mileage of

99 iron axles = 216,857 miles;
47 steel axles = 156,115 miles.

From these figures it will be seen that the "iron" axles appear to have an advantage in mileage, yet it is a well-known fact that "steel" is much the stronger, and fewer steel axles failed. It is often stated, and is almost taken for granted, that a crank-axle is, and must be, weaker than a straight axle; but there seems to be no proof that this is the case in practice.

I have carefully worked out the various strains upon a crank-axle due to direct weight, leverage, and force of steam acting on the pistons; but they fall far short of the force which would be sufficient to break a good sound axle. What is it that breaks a crank-axle? This is a question constantly asked, but so far not clearly replied to. If the weight and pressure of steam is not enough to account for the failure, other reasons must be looked for.

When an engine is running at high speed there is a greater or less amount of oscillation; this is kept in check by the flanges of the wheels, and great strain is put on the axles. Points and crossings are generally laid to gauge or even tight, and it frequently happens that the flanges of the wheels are thus pinched, and it will be at once seen that this action must exert an enormous force upon the axle by the tendency to bend it upwards in the middle. This force is greatly increased with the size of the wheel, as the leverage or length of the spoke is greater.

It seems perfectly certain that the strains, which increase growing flaws, and ultimately end in a failure, are in a very great measure due to the force communicated to the axle by the wheels and flanges. This side thrust is therefore a matter for very serious attention, and having expressed the opinion that one of the principal causes of axles breaking is due to it, I have advocated the driving-wheel flanges being turned thinner than the others, in order to avoid the side shocks and pinching action as far as possible.

It may interest your readers to know that the whole subject of "axles-breaking" is engaging the most careful attention of the Leicester branch of the Amalgamated Society of Railway Servants; two evenings have already been devoted to it, and it again stands first on the notice paper. Various valuable details have already been brought to light in the course of the discussion by these practical men, and all possible data have been obtained from every important line in the kingdom. It is well known that axles break "at growing flaws"; now how do these "flaws" begin? Are they in the metal at first, or do they begin *after* the engine has been running? If the latter, what cause is it that starts the flaw? Should an axle, after running a certain number of miles, be taken out and disused? These are some of the points upon which, as I have already said, more information is required before a sound opinion can be expressed.

**Clement E. Stretton, C.E.,**
Hon. Mem. A.S. Ry. Servants.
Leicester, April 18.

### LATHE MATTERS.

[24157.]—I do not, myself, regard anything but an edge tool as legitimate to act on soft surfaces; but my experience is, as is that of others, really limited as yet, in many ways, and so I do not venture to express any opinion on the matter of diamond-set laps; they seem to have given satisfaction to Mr. Hines and others to a considerable extent, however.

Diamond, from its splinter-like nature, I should have been especially doubtful of, and, following my natural bent, should have first, on going to use it on soft metal, have tried to firmly imbed the sparks with a hard steel roller, afterwards going over a try-surface to test their hold and remove loose ones. The difficulty or impossibility of burnishing off the edges of any bits accidentally left in the surface acted on, would have made me additionally chary of using it. I have no present intention of either advocating its use, nor of trying it. It is my present opinion that a cutting tool would best give the amount of accuracy and finish necessary for a soft-nosed mandrel, with a hardened and accurate cylinder centring. If the outer end or tip of nose is preferred hardened, to prevent wear or bruising, without weakening the hold-fast strength of nose, I may have to change my plans.

I have had experience of getting soft bearings to great accuracy; I have no wish to add to it. You can hardly touch a soft surface with anything that will not set in it, more or less, and when you have got it up, by dint of carefully setting up your centres, straining spring out, or to a minimum, getting up high speed without vibration, extra hardening your tools, shaping them with a lens, and then polishing them up, then finishing, at much expense of time, with a soft bit and rouge; you have only to look at it to scratch it. When this latter feat is accomplished, you must either begin again, or be satisfied with unfaithful work, for the alternatives are either to true it up again, and re-polish all over, or to polish out the scratches, in the first case reducing the size, and in the second, producing little depressions where the scratches were. No measuring tests can, perhaps, detect the error; but it is there, and in the course of time would have its due influence and effect.

I am glad to note that "J. K. P." is satisfied with the accuracy obtained by "touches in a screwing lathe," and is not like some foolish workmen of whom we read, that they found their work but seldom to their liking. I have hopes that I may attain to about the same pitch of perfection in the tools and instruments I am designing and making. Dr. Edmunds, also, who is anxious to raise the particular branch of mechanical work he affects to such perfection as art and science may admit of, and industry accomplish, will be cheered greatly. I do not wish to "poke fun," but to hint that there is work to be done of a somewhat higher class than a screwing-lathe and edge-tools can accomplish; and that there is one section of the English Mechanic readers and correspondents who are aiming in this direction.

"What I know that I know," is impressive; but in a recent discussion on friction did not appear quite the case.

So (24115) I should, though tempted by the "cui bono" not to do so, like to point out that "a cutter with a distorted periphery" is not the tool in question; it is a lap-wheel to be set with diamond sparks, and of a true periphery. Has a Morse drill a distorted form because, though ground out by an angled circular cutter, it has a straight tip?

If it were a cutter, "in order to be an efficient workshop tool," the teeth would be cut out roughly by files, cutters, or sliding tools with ease and speed, and the edge would have to be given by grinding and sharpening after hardening. There would be no great difficulty in making one by hand, if the axial line to cut the teeth to were marked in place as turned; the lines would be straight, and of the true thread angle, though the edge of cutter would be axial to screw, and inclined to its own axis. After hardening, if distorted much—and it ought not to be if properly treated—there would be some trouble with it, perhaps; but in a workshop, amongst workmen, there would be no real trouble at all. If in demand, they could be had as cheaply as any other simple form.

If it is desirable to reverse chucks, how will the cone-nose advocates do, or how have they missed the point? In a cylindered mandrel the prevention of reversing would be a safeguard to centring.

I grow more and more astonished at the amount of discussion and quasi-relevant recriminations that can arise from trifles, more or less. I hope it will continue to be the case: otherwise we shall actually begin to make progress. **Vulcan.**

---

[24158.]—I had some doubt, after letter No. 24114 was written, whether I might not have blundered, by failing to make a distinction between the action of square or rounded-edged cutters (or grinders) as applied to cylinders, and those which have angular edges, whether symmetrical or not.

I have since made an experiment on a large scale, and am convinced thereby, as well as by the opinion of a very experienced practitioner in that direction, that I may let that letter go down to "die Ewigkeit" by only correcting a word or two.

In p. 149, first column, line 17, the fitting in question is a female mandrel, broad-flanged, commencing with a cylindrical hole, and the internal screw a good way inside from the front. This fitting, I learnt from Mr. Clements's lathes, for which I once had more reverence than I now have; but I like it for this purpose, as, in a drill spindle used in the slide-rest, the less the drill projects the better, and the drill-chuck and all the fitting portion of the drill-stem are in this construction contained within the body of the spindle.

Line 39 down, "referring" should read "refers," and about 31 lines lower, "mean depths" should be "mean depth." Four lines lower, for "in outline, is," read "is, in outline." Three lines from bottom, for "that purpose is," read "for that purpose mine is." I wish to repeat, that any knowledge I possess I will give freely to any ordinarily civil inquirer; but I will not argue. If I make a statement, I do so confidently, as knowing that what I say is right; if I have a doubt, I will admit the same. **J. K. P.**

### TRUEING MANDRELS.

[24159.]—It appears to me that the method of "trueing up" maudrels, described by Mr. Wenham, (in 28882, page 560), is not strictly or critically speaking, a method of "trueing up" at all; for though errors might be reduced by continued working, they could not, in the nature of the process, be eliminated; in fact, cutting tools, unless bent into rigidity, and set in mechanisms also rendered sufficiently rigid, and acting upon rigid or already true and homogeneous substances, cannot turn out true work—work that will stand critical tests.

Paper rolls of chilled iron are turned very approximately true by diamonds, but they are of comparatively large diameters, and rigid in themselves, and spring at point of tool is of less effect than for smaller diametered lathe mandrels. With the very light cuts, and a "stout rod," which, however, has its liability to spring, recognised in the directions "below the centre," &c., very approximate results might be got; but unless the mandrel was homogeneous and true to begin with, the tool and work would spring apart, more or less, at the hard portions and protruding portions, continually reducing inaccuracies, if kept constantly traversing to and fro, but never eliminating them. As "F. A. M." said, regarding his centre cone, the which he scraped into truth, "we cannot turn true,"—we cannot, that is, by the methods in vogue.

The attainable set-offs against uneven hardness or contours, to be made true, are high speeds and rigid tools; in the former case, the inertia of the work comes in as an equivalent of rigidity, and also, while there is no vibration, as a cause of true running, small disturbing causes have their actions equalised, or have not the time to produce the effects they would at slower speeds.

For "trueing," high-speeded revolving laps, such as are generally in vogue (I have seen some very large surfaces treated in this way), are certainly more capable than cutting tools at slow speeds; in the soft state, very good results can be got by very hard tools, light cuts, and high speeds; but for hard material, it appears to myself that a high speed on the object, a stretched or otherwise made rigid tool or apparatus, and fine multiple cutters—an abradant, in fact, first with one facet, to produce, as near as possible, circular contour, and then cylindrical form, and finally with multiple facets, and properly ordered motions—following in the wake of the opticians—and fine rouge, to produce the highest attained accuracy and polish,—would be the way to go to work on a really fine mandrel.

I think, also, there is room for tests, to detect lack of homogeneity in soft state, with a view to its correction in the hardening. It is more needed after hardening than before it. **Vulcan.**

### DIAMOND TOOLS.

[24160.]—Since writing my last letter I have paid a visit to my father, who, though no longer in business, still keeps on an amateur workshop. The business I now carry on was founded by Cawdron, my great uncle, who was a compeer in ornamental lathe-making with the original Holtzapffel. Cawdron used diamond tools for trueing up hardened steel mandrels. Three of these tools came into the possession of my father, all of which I recollect when a boy, and, though the largest of these has disappeared, my father has hunted up two of them, and they are now in my possession. These can be examined by any one who will give me a call. No. 1, which appears to have been most used, is a long triangular-shaped splinter, the greater part of which is buried in a copper rod, showing an angular point or edge, which is somewhat injured. No. 2 has evidently been fractured somewhat in use; but has still an edge or point which will cut.

No one doubts that the diamond is capable of paring down hard steel; the only question is, whether its use, now that we have modern methods of emery and other grinders, will ever become of workshop use except in very special cases? These tools will be found to be very expensive, difficult to set so as to stand their work without breaking off or getting loosened, and very uncertain in their work. They cannot be ground down to an effective edge upon a diamond lap, as Mr. Wenham thinks.

The only kind of diamond that will not break away is the carbonado. This is so hard that the skyfe will not touch it; or only with so much injury to itself that the professional diamond-cutters will have nothing to do with it, and, if they would, only at great expense. Then, again, Mr. Wenham is entirely wrong in this idea of sharpening up the above, like grinding up a lathe tool, for when once the natural angle with its outer skin is gone, that portion of the stone is useless, and the only way is to reset it so as to bring out another natural angle.

The work done by the diamond upon hard steel is not the most satisfactory, and such work can not, in this manner, be finally finished up suitable for such sliding work as the traversing mandrel; but in all cases must afterwards be laboriously lapped up true; consequently, the tool is really of but little practical use.

Mr. Wenham writes as if Dr. Edmunds had suggested to cut the screw-threads with diamond grinders. All he has suggested is, that in certain cases where hard steel hobs or screw-noses are required of extreme accuracy, they may be trued up to the extent of reducing the surface a fiftieth of an inch.

In fact, there is little need to take any such trouble with the Edmunds mandrel-thread, insomuch as it is left rather an easy fit, and the set of the chuck is secured by the true face-zone and the true cylinder-base. What Mr. Wenham says, is that "a revolving V-cutter (50°) does not cut the same groove as a fixed-point tool of the same angle and equally tilted for the rake of the thread."

That is a point upon which I say that Mr. Wenham is in error.

Griffin Works, Norwich. **Edward Hines.**

### MILD-CENTRE STEEL.

[24161.]—In reply to Mr. Wenham's remarks about mild-centre steel, I beg to inform you that it is made by all Sheffield steel makers nearly, and I believe is made thus:—A round bar of iron, heated to a certain point, is placed in the centre of the mould, and the steel poured round it.

**H. Gilbert.**

### MERCURY AS BALLAST.

[24162.]—Fill a quill with quicksilver, cork the ends tightly, place it in the middle of a loaf when being put into the oven; and the loaf is sure to jump out of the oven in the progress of baking. This is a statement of a curious experiment which I heard when a boy. I am now an old man, and I have never heard it contradicted; but, not being a baker, I have not been able to try it. However, it may go a great way to explain the value of mercury as ballast. **Rho.**

### POWERFUL OPERA-GLASSES.

[24163.]—Since my last (p. 522) of 6th February, some delay has occurred through maker No. 2 having proposed to raise his prices. Maker No. 1, however, undertook to replace his work for lower, instead of higher prices, and has now sent over excellent specimens of the three sizes of instruments, already fully described on page 285, Nov. 28, 1884. An advertisement showing how they may now be obtained has been inserted on the front page in this issue, to save correspondence with so many of our readers who have written about them.

For the benefit of tricycle riders, I should mention that, as the result of his visit to the above maker in Paris, "Faber" returned with a glass 1¾in. diameter of barrel, 3in. in length, with ½in. focal play, so as to be always ready at focus in his pocket, with a power of 4 diameters; being probably the maximum example of instantaneous utility, high power, and portability yet achieved, its weight in aluminium being only 2¼oz.

**Montmartre.**

23, Park-crescent, Portland-place, W.,
April 20.

### LECLANCHE CELLS.

[24164.]—I notice the reply of "Rho," letter 24108, on this subject, with which I concur, with the exception of the prices assigned for manganese, 6d., and carbon 4d. per pound.

Those are very much too high. Manganese of the best quality can be bought at 4d. per lb., and carbon 2d.

This, of course, will very materially reduce the cost of each cell. **Geo. G. Blackwell.**

26, Chapel-street, Liverpool.

## REPLIES TO QUERIES.

⁂ *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[54825.]—**Salt, &c.**—It appears to me that "F. W. H." overlooks the real point altogether in the questions he puts to "Marienberg," as well as merely word playing on the terms natural and non-natural. It's either true or not true that the cereals will perish if not cultivated by man; evidence has been asked for either way, and it has been given so far as to show that they will perish if left to themselves, for even "Backwoodsman" admits that by the fifth season the wheat was choked off, and I know in this climate it will not survive one if left to itself. I would also remind "F. W. H." that the existence of primitive man is ouly a supposition, which has never been proved. The remains of the earliest men found in Europe, who lived up to the ice border, show plainly enough that whether they lived 3,000 or 300,000 years ago, they were certainly not primitive, and although, so far as I know, a ploughshare has not been found, grains of corn and cakes of baked bread have been, and that fact will serve as well, I think, and perhaps better, than finding the "fossilised ploughshare."—Dens

[55484.] — **Water - Pressure (U.Q.)** — Your sketch shows sides of indefinite thickness, as in a reservoir. This looks as if you wished to know the pressure against sides per unit of area. If H = depth of water in feet, the mean pressure on sides is 31·2 H pounds per square foot. The pressure per square foot at any depth, H = 62·4 pounds. If the reservoir have sides, *t* inches thick at the point H, the stress per square inch on the material of which the tank is made is $2{\cdot}6\,\frac{HD}{t}$, where D = diameter of tank in feet. The shape of middle of tank has no influence on the pressure against the sides. The same rule, 62·4 H, gives the pressure per square foot on any part of the bottom.—Glatton.

[55700.] — **Strength of Shafting.** — "One Ignorant" must excuse my delay, as my "E. M." has been at the binder's, and I could not refer to his query. If he works out the power again, he will find that he has made a mistake: the 6in. shaft comes out exactly nine times as strong as the 2in. one. I inclose a demonstration of the fact that the strength of a shaft varies as the cube of its diameter. Let a shaft (Fig. 1) be broken by twisting. Just before twisting off, the fibres are distorted and stretched as shown in Fig. 5, and two marks, *a* and *b*, which coincided before applying force, are separated by a small angle. The distance of *a* from *b*, measured on the circumference of the shaft, shows how much the fibres are stretched, and is a measure of the stress, or pull per square inch, on each of the outer fibres. When this stress exceeds a certain limit the outer fibres break, the next ring of fibres have an undue load, and break also, and the whole shaft gives way. Let Fig. 2 represent one end of the broken shaft, and let it be divided into four rings, of which the width = W = ¼ the radius of the shaft. At a radius of half the outer one, the fibres are stretched only half so much as at *a b*; (*c d* = ½ *a b*) at ¾ the radius this stretch, and therefore this stress, or power of resisting torsion, is three-quarters that at the outside, and so on. At the outside of a shaft of half the diameter (see Fig. 3), the stress when breaking is again equal to the shearing stress of the material, and is thus the same for the outer layer of any shaft of the same material. Dividing this section into the same number of rings as Fig. 2, we again find that the nearer we get to the centre the less the strain becomes, and at a radius *r*, which is of course half the radius R, the fibres are stretched to the same amount. The width of the ring (1) in Fig. 2 is twice that in Fig. 3. The circumference is also twice that in Fig. 3. There are, therefore, 2 × 2 = 4 times the number of fibres acting. They are acting at a leverage R, which is twice that in Fig. 3, which is *r*. Four times the number of fibres, each set with the same average pull, means four times the total pull. This at twice the leverage = 4 × 2 = 8 times the total force acting at the centre of shaft. This may be proved to be the case for any number of similar rings in Figs. 2 and 3, and we therefore find that the resistance due to all the rings in Fig. 2 is four times that due to all the rings in Fig. 3. That is, a shaft which is double the diameter of another is four times as strong. In the same way, it may be shown that a shaft three times the diameter is nine times as strong, and so on.—Glatton.

FIG. 1.

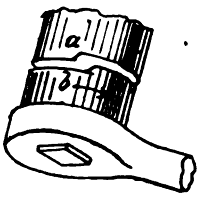

FIG. 2.

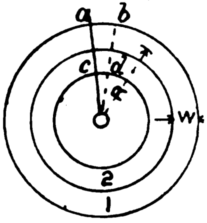

FIG. 5.

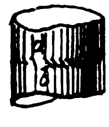

FIG. 3

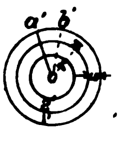


[55930.] — **Self-Winding Watch.**—I gather from the following that something superior to the self-winding movement depicted by "Annie," on p. 108, is in the market. Perhaps some of our American friends can give more particulars. The movement on p. 108 is Loehr's "Perpetual," but it appears that a watch has recently come into the market, which may justly claim every qualification called for by the term "self-winding," without possessing any of the drawbacks or imperfections hitherto encountered in all works of that description. In quality similar to the A. M. N. Waltham movement, as are also the whole train, escapement, balance, mainspring, &c., everything is correctly proportioned with due appreciation of the popular demand, and in strict obedience to the laws governing the manufacture of any first-class, well-regulated, and thoroughly reliable watch. The mechanism of the movement, by its very simplicity precludes possibilities of disarrangement, while the process of winding is as positive and thorough, whether the watch be carried by a person of sedentary habits or by one given to more or less violent exercise, such as riding, dancing, running, &c. No matter how severe or continuous the motion of the person carrying this watch, the mainspring can never be wound up beyond its last quarter, as the pendulum will then cease its motion. This peculiarity deserves special mention, for, in addition to its simplicity, its action is absolute. In former specimens of self-winding watches the process of winding was made more or less unpleasant to the sense of hearing, on account of a peculiar clattering movement of the pendulum. This defect, nor anything approaching it, does not exist in this movement. If required, the mainspring, when wound up, can be unwound at once, without removing any part of the mechanism; or, if so desired, the whole case containing the mainspring can be taken out singly without disturbing the rest of the movement. The patentee is Mr. H. von der Heydt, of Chicago, Ill., and if his winding movement will do what is asserted, it is certainly an improvement.—W. M.

[56025.] — **Trueing Grindstone. — Patent Law.**—One of the objects of the reply on p. 66 was to enforce and emphasise what I had before stated in connection with patent law, &c.—that it is morally wrong, and also illegal, to make and use a patented invention, unless, indeed, one is prepared to dispute the validity of the patent. On p. 277, Vol. XXXIX., I explained that the prohibition clause in the "Letters" had been altered, and now reads "make use of." It was also pointed out that it is legitimate to make a patented invention for the purposes of experiment; but not to use the invention in the ordinary meaning of the term. On p. 108 "Z. Y. X." wrote: "I agree with 'Nun. Dor.' that, notwithstanding the words of the prohibitory clause in a patent, a man may make a patented machine for the purpose of seeing whether it can be improved"; but previously (p. 40) he reminded your readers that the prohibition clause is against making, using, mending, or exercising the invention. Having already shown that the prohibition clause does not say that one shall not make, I do not see what purpose would be served by following "Z. Y. X." in his appeal to the granting clause. Does he contend that the granting clause is more potent than the prohibition clause? Does he hold that we must not make a patented invention for experiment, or what does he contend? I confess I cannot see his point. I do not know of a single judgment which refers to the granting clause, and I do not remember an advocate using its phrases as the foundation for an argument. If I were inclined to split hairs, I might point out that there is a considerable difference between "and" and "or"; but I am not. I would, therefore, ask "Z. Y. X." to kindly correct anything that may be wrong in what I have stated, and so help to convince some of your readers that they must not use patented inventions, even privately. Perhaps, without appearing egotistical, I might say that I quite appreciate the difference between the "granting" and the "prohibition" clauses, and yet I fail utterly to understand what "Z. Y. X." means in his latest reply (p. 152) when he says I have failed to see the true import of the words in the patent. Will he kindly explain what is their "true import"?—Nun. Dor.

[56041.]—**Gun-Metal.**—"Nun. Dor.," with all deference to him, confuses gun-metal with metal for guns. Metal for guns may be gun-metal (copper, tin, and zinc), or it may be bronze (copper, tin, zinc, and lead), or it may be cast iron chilled in its core, or it may be cast steel (very soft) or it may be steel (in strips like the Armstrong), or it may be Delta metal (which does, so they say, contain iron), or it may be any other material (whether ordinarily called a metal or not); but I venture to think, notwithstanding "Nun. Dor.'s" remarks (p. 152), that gun-metal is a well-known article of commerce used for many other purposes than for guns, and I again venture to ask whether gun-metal, as ordinarily spoken of, contains any iron at all. Now, oddly enough, the letter of "J. C." preceding "Nun. Dor.'s" (p. 152) gives, as I think, the true description of gun-metal—and for this information I thank him,—Copper, tin, and zinc, or copper and tin; and he quotes Tredgold and Smeaton as to the qualities, &c., of gun-metal. I well recollect Uchatius's great advent and subsequent disappearance; but I thought that was steel, and not bronze. Now for an answer to "Nun. Dor.'s" not unreasonable question "what he (I) meant by asking on p. 66 in the words 'Is it really the fact that these four metals can be melted together'?" Now, what I meant was this. Gun-metal, a well-known article composed of copper, zinc, and tin, or copper and tin only, is made in tons in almost every brass foundry. By the way, brass is first cousin to gun-metal, and is composed of copper and zinc, and tin being added to the copper, with or without zinc, forms gun-metal. This compound called gun-metal is generally supposed to be difficult to get of a uniform quality at different meltings (same with brass), in consequence of the difficulty of keeping the zinc from volatilising at the heat, which is necessary to keep the copper liquid, and all sorts of contrivances are resorted to to keep the zinc from flying off and being lost. Not so much difficulty when copper and tin are melted together. Now, I thought that the introduction of iron would add greatly to the difficulty, and I still think so, and, further, I believe still that gun-metal as a commercial article, and well known in the trade, never contains iron in large or even small quantities.—A. P. Bower.

[56082.]—**Telephone Transmitter.**—Suppose this querist refers to the back numbers containing diagrams of different transmitters—Nos. 695, 747, 865, for instance.—Lex.

[56093.] — **Pitch Grease.**—I don't know "pitch grease" by that name; but if the querist will melt his tallow and add one-seventh of its weight of sugar of lead, and when that is dissolved, about one-fifth of black antimony, stirring well together until cold, I think he will have something which should be very like what I imagine is meant by pitch grease.—Essar.

[56099.]—**Faulty Leclanche.**—This fault cannot well be detected without examination. I suppose the blocks are not exhausted.—C. J. M.

[56110.]—**Mill Bills.**—There are a variety of recipes for tempering mill bills given in back numbers, but there is no royal road to success. The querist must study the nature of the steel, and learn when he has it at the right heat. Then quench in water—plain water, for chemicals can certainly have little to do with the matter. Here is one recipe: To three gallons of water add 2oz. oil of vitriol, 2oz. of soda, and ½oz. of saltpetre. Here is another: 1oz. each of white arsenic, spirits of salts, and sal-ammoniac, dissolved in four gallons of spring (!) water. Will any of your readers tell me what possible effect any of these mixtures can have on the temper of steel? "P. M.'s" best plan will be to have a clear fire, and judge of the colour of the heat in the dark; for most cast steels it should be a bright red.—Essar.

[56112.]—**Testing for Arsenic in Wall Paper.**—Mr. R. Forrest, in his critique on my reply to the above, says: "The simplest and readiest way to distinguish arsenic from antimony is, &c." The query is not how to distinguish arsenic from antimony, neither does antimony, as far as I am aware, find a place as colouring matter in wall paper.—J. Kean, Northampton.

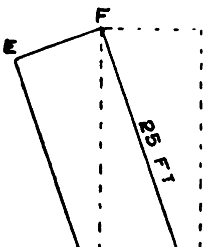
[56117.]—**Pacinotti Ring.**—"Electra" has evidently seen neither a Pacinotti ring, nor a Brush. In the Brush, every alternate coil is connected, in the Pacinotti, *not*. What Mr. Bottone illustrated are not "collecting strips, or collectors"; but the brass strips of the commutator. The collectors or brushes were not figured at all.—S. Bottone.

[56125.]—**Staining Buckskin.**—If "D. G." wants to stain or dye his gloves "mouse colour" why does he want to use pipeclay as the staining vehicle? I think the best plan will be to mordant with a weak solution of phosphate of soda, 1 to 100 water, brushing that over three or four times; then brush elderberry juice over twice, and finish with a weak solution of nigrosine—a one per cent. solution.—Dyer.

[56132.]—**Cutting Pipes.**—Mr. Geo. A. (F.) Walton and I are showing pretty clearly that—

> "'Tis with our judgments as our watches, none
> Go just alike, yet each believes his own."

Mr. Walton (p. 67) replied to this query, and I undertook to point out that he had got rather mixed in his calculations. As "M. B. M." asked for his required information in such very definite terms (viz., "B to E is the length I want"), I did not care (like Mr. Hardie) to tell him that that length alone would be of little or no use to him. I preferred (p. 109) to answer his question as it stood, and to suggest to him, in a gentle sort of way, what I thought would be a necessary change in his proposed mode of carrying out his ideas. As the matter stands now, Mr. Walton says that I am in error, and I think that he is in error. I would like to meet him half-way by pointing out where I think he was, and still is, in error; and I hope that, in return, he will point out where "my answer, as well as my method, is in error." It will put the matter before "M. B. M." in rather a clearer light. We will take "M. B. M.'s" sketch as it stands. (I may be allowed to reproduce part of it here.) Angle F B C is a right angle, so is F E B, and length of F C is 25ft. Find length of E B. Mr. Walton is in error in supposing E B to be equal to F B, and that error vitiates his whole work. I see now the slip to which Mr. W. alludes—he put 225 for 625—but taking it as corrected, the reply is still wrong, as it gives the length of F B, not of E B. The latter I have shown to be 23·56ft. in length. I hope that Mr. Walton will now show where my answer or method is in error; also, if he can suggest any fairer and more candid way of getting rid of the discrepancy between our replies, I will be glad to adopt it.—Jno. M. Adams.

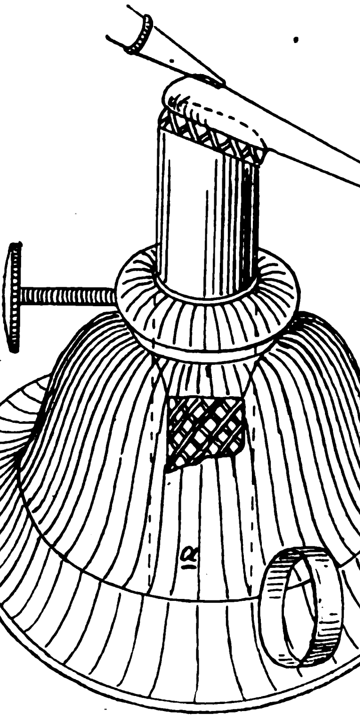


[56137.]—**Tracing Paper.**—After a number of experimental trials made years ago, and with a variety of ingredients, I found the following succeed so well that I adopted it for mechanical tracing. Melt by heat 1 part of fine rosin in 1 part of boiled nut oil, and, whilst still warm, add 6 parts of spirits of turpentine; all by weight. Apply the mixture when cold with a small bunch of calico. As each sheet of tissue-paper is done, hang it on a line to dry. It is very transparent, and takes on ink or colour well, and it does not turn brown by age.—Draughtsman.

[56142.]—**Wheatstone Bridge.**—The carbons, ⅜in. diameter and 2ft. long, are about 10 ohms resistance; some the same size are only 8 ohms, so must be tested to know accurately. If the querist has a 5-ohm coil, and wants to make another like it, the simplest way of going about it is to connect the 5-ohm in circuit with a constant battery and galvanometer—say, it gives 20°—remove the 5-ohm coil, and insert sufficient length of wire until a deflection of 20° is again given; then the wire inserted will be equal to the 5-ohm coil. If you use the bridge for this, you must have resistances in the two left-hand openings, A and C, or the galvanometer will be short-circuited. Make this the rule: let the two left-hand openings be fixed resistances—say, 10 ohms each; the bottom right-hand, D, the resistance to be measured, and the top right-hand, B, the adjustable coils. To give you the key to the whole affair (free from algebra or mathematics), I quote from "Culley," p. 216:—"To measure a resistance *greater* than that of the coils at B, the resistance of A is made less than that of C, and the reading at B is multiplied by the ratio between them. Let A be made 1 and C 1,000, or let them be in the proportion of 1 to 1,000, and let the reading at B be 2,000, then A : C : : B : D or 1 : 1,000 : : 2,000 is to 2,000,000, the resistance measured. When the resistance to be tested is *less* than can be measured by the coils at B, A is made greater than C; thus let A be 100 and C 10, or in the proportion of 10 to 1, and let the reading at B be 1, then A : C : : B : D or 100 : 10 : : 1 : ·1. Thus, the resistances of A and C can be varied at pleasure, until they bear such a ratio one to the other as will enable the coils at B to balance the resistance in D, when the resistance is found by direct rule-of-three."—M. S. E.

[56242.]—**Relation between Size of Dynamo and E.M.F.**—To Wm. Grey, F.C.S.—This is very little understood. Many suppose that the E.M.F. depends on the number of coils and the speed of rotation of armature. So it does to a certain extent; but if you have no iron in the fields you get very little or no current. According to my own experiments, which I will publish in full shortly, each 1lb. of best soft Swedish iron in the field and armature together, driven at the best speed, is capable of furnishing two volts of E.M.F. The current in ampères of course is decided by the sized wire employed. For instance, a dynamo, which weighs 10lb., wound with 7lb. of No. 16, R = 1·34 ohms on the fields, and with 6oz. No. 20, R = 0·5, total R = 1·84, has an E.M.F. of about 18·5 at 3,000 revs., and gives a current on short circuit of about 10 ampères.—S. Bottone.

[56250.]—**Engine Making at Home.**—Make the bedplate of solid stuff by all means. Respecting the dimensions, we agreed that lengths of rods and centres of motions should be halved exactly, but that dimensions for strength would have to be greater than half, which dimensions should be taken in detail. Go on with the cylinder to the new dimensions given; and for the bedplate prepare a block of mahogany not less than 2in. thick, more if you choose, and measuring roughly 2ft. in length by 5in. wide. Plane it to a parallel thickness, and square one edge. Draw a centre line down its face with a gauge laid against the squared edge. Draw the centre line of the cylinder across at a distance of about 4½in. from one rough end, and from thence mark the centres of guide-bar bosses and crank bearings. When the cylinder is made, screw it down with small wood screws. I should attach all the work before finishing the edges, since if the moulding were worked before the engine was fitted up, it would get dirty, and the screws would be more likely to split the grain.—J. H.



[56303.]—**Blowpipe Petroleum Lamp.**—I am glad to see one of your correspondents taking up this interesting subject to which I have referred in my last work in the following words, "I believe a good deal could be done with a petroleum lamp; but having never tried one, I shall, as Berzelius says, pass it by here ("The Blowpipe in Chemistry, &c."). The field is, therefore, entirely before your correspondent "$H_2$ S." ("E.M.," No. 1,045, page 113), for no one has yet described such a lamp, and I, for one, shall be very pleased to hear what results he obtains from this lamp, especially in using boric acid as a reagent. According to the custom which makes the "E.M." such a universal favourite in Britain, Germany, and America, I send the sketch of a petroleum lamp sent me some years ago for trial by my friend Mr. Frank P. Williams, the manager of some large metallurgical works in Llanelly, Wales, and, I believe designed and made by himself. He is an old Freiberg student, and a man of first-rate ability. A brief description of the Fig. will, no doubt, suffice for "$H_2$ S.'s" comprehension. The dotted lines show the section of a tinplate tube, which is carried through the centre of the lamp to its bottom. This tube is perforated by five large large vertical slits reaching nearly to the bottom, giving it the appearance of a series of railway arches. Through those slits cotton-wool is stuffed with a knitting needle, or similar instrument, until the lamp is loosely filled with it, except the lower part of the centre tube (at *a* in the Fig.), which is left vacant for the bottom of the plaited wick to hang, and suck up the fluid paraffin there. The lamp is thus rendered portable without fear of extensive leakage.—W. A. Ross.

[56271.]—**Portable Engines.**—To "Invicta."—Many thanks for reply to query. I can see by drawing the way to make barrel part of boiler, but do not quite understand how firebox is made. I want it suitable for a coal fire. Would this be large enough to work a sewing-machine?—A New Subscriber.

[56272.]—**Lifting Water.**—300 tons in 24 hours $= \frac{300 \times 2240}{24 \times 60} = 467$lb. per minute; $\frac{467 \times 90}{33000} \times 1·5 = 1·27$ horse-power. This allows for a loss of one-third of the power through friction. Allowing actual pump barrel to be 25 per cent. larger than the theoretical, the buckets will sweep at each stroke, if single acting, a volume $= 27·73 \times 467 \times 1·25 \times \frac{2}{12}$ cubic inches, supposing the twelve strokes to be six up and six down. If twelve up and twelve down, multiply by $\frac{1}{12}$ instead of $\frac{2}{12}$. If double-acting, the volume swept by bucket will be half that swept by a single-acting pump. Of course the diameter will depend on the length of stroke. The area of bucket multiplied by length of stroke will equal the volume swept by bucket per stroke.—Glatton.

[56273.]—**To Mr. E. Eaves, Coventry.**—I shall require the motor for about two hours one day a week. It is made from instructions given in the "E. M." by Mr. Chaster. Will you kindly give me instructions to make an accumulator to light three 10 c.p. lamps for about three hours, to be charged from a dynamo half the size given in No. 1007? Also, how long it will take to charge it, and how

I shall know when it is fully charged.—J. J. HAMMOND.

[56288.]—**Crankshaft.**—Depends a good deal on facility of construction, and on appearance in so small a model. I should say from $\frac{3}{16}$in. to $\frac{1}{4}$in. Balancing not worth while.—GLATTON.

[56289.]—**Exhaust-pipe.**—I will answer this query by asking another. On page 12 of this volume, "Exhaust" mentions an alteration in position of blast-pipe, with improved results. As presumably your blast is strong enough, it would appear that by lowering your blast nozzle you could enlarge its diameter without impairing its efficiency. Will "Exhaust" tell us if the noise of puffing was diminished in his case?—GLATTON.

[56296.]—**Sand-blast.**—Particulars and illustrations of three forms on p. 235, Vol. XVI. Another design, which I have not tried, on p. 314, Vol. XXVII.—GLATTON.

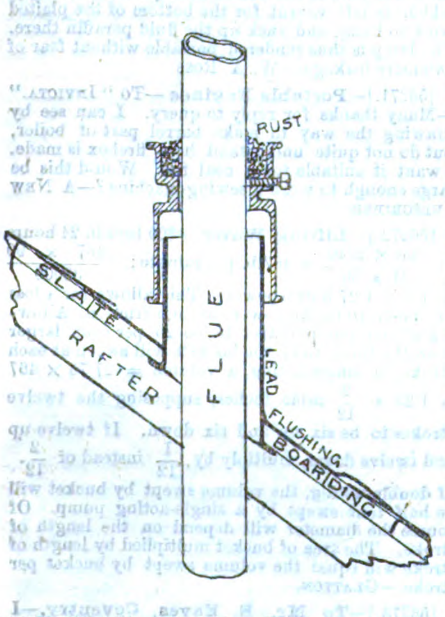
[56320.]—**Dynamo.**—If a good strong man were set to work at about 6 a.m. and ground away till about 6 p.m., he might (?) possibly charge the accumulator sufficiently to light the said lamps for a couple of hours or so. But I should advise the said man to invest in a cinglet beforehand, or he would most likely take a violent cold from the profuse perspiration into which he would be thrown.—S. BOTTONE.

[56321.]—**Indicator Diagram Paper.**—The paper for this, as for the indelible notebooks, is, in the making, loaded with China clay; the better sorts with fine bone dust from burnt bones. I find whiting, rubbed on with a bit of clean waste, answers nearly as well. A stroke with the blunt point of a brass pin makes an indelible mark. Writing paper too highly glazed, or if handled too much, will take ink perfectly if rubbed with a little whiting.—DRAUGHTSMAN.

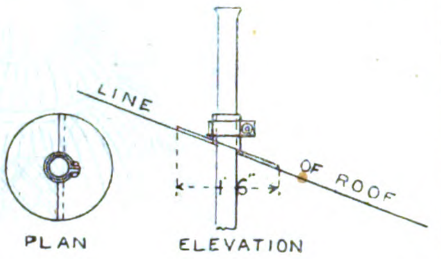
[56326.]—**Sketching.**—In sketching from nature, where accuracy is aimed at, great aid may be found by tying a card at the end of a thread, the other end knotted and held between the teeth. If the card is a strip nearly as long as your drawing, all the better; the thread to be of such length that the card will touch the drawing. Shut one eye, and holding the card in the direction of the object, measure by marks on the card any dimension you require, and transfer it in its proper position to your sketch. Those who have not tried this plan, which was shown me first by an artist relative, will be surprised at the accuracy in detail that a very little practice will achieve. I have sometimes used a scale for the purpose, but a card is handier. With a steady hand, the proper inclination of lines may be obtained as well as their apparent length.—DRAUGHTSMAN.

[56331.]—**Chimney Pipe.**—Fix a thin iron sheet on with set screws tapped into the cast iron. Make a tight joint with asbestos, if you are not a good enough workman to make a fit without. Joint the sheet with the slates as if it were a large slate.—GLATTON.

[56331.]—**Chimney Pipe.**—The annexed sketch will show "H." the method I adopt to keep the roof weathertight; but if my meaning is not clear to "H.," I will reply again. The hole in the roof is cut 2in. larger in diameter than the flue, and a lead or zinc pipe is fixed into it. This pipe should project at least 6in. from the roof at its lowest part, and must be flushed all round with lead or zinc. On to the flue is fixed a cast-iron cap which covers the lead pipe, but does not touch it, there being a space of 1in. all round. The cap is prevented from slipping by three set screws, which also serve to set it concentric with the flue. In the upper part of the cap a recess is cast, into which is packed rust or asbestos putty.—AREFES.

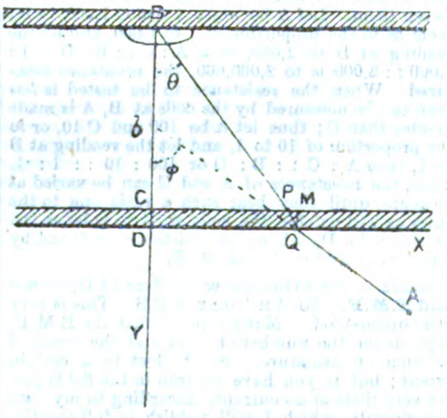


[56331.]—**Chimney Pipe.**—A rigid joint in roof would not do, because expansion must be allowed for. I have had the same difficulty with a pipe taking exhaust steam through slated roof, and have cured it by attaching to the pipe a circular disc of galvanised iron made in halves and overlapping at the joint. The disc is bent to the pitch of the roof and is placed over the slates, but not attached to the roof in any way. A semicircular collar is formed on each plate, the two, when brought together, forming a complete collar round the pipe. A wrought iron clip round the collar keeps the whole in position, and a lining of red sheet indiarubber (such as is used for steam joints) prevents water coursing down between collar and pipe. The sketch herewith will, I trust, serve to make the matter plain.—SILEX SEADRIFT.



[56331.]—**Chimney Pipe.**—Surely, if your pipe gets hot enough to melt solder, the rain that runs inside won't cause much trouble! It would vanish in the shape of steam. Try equal parts of red lead and white lead mixed for cement. That will take to the iron and slate; the heat won't affect it.—GWENT.

[56332.]—**Optical.**—Let B P Q A be the course of a ray of light proceeding from B to the eye at A. Let Q M be perpendicular to P C. Let A Q cut B C D at $b$. Let the angle C B P = $\theta$, and the angle C $b$ Q = $\phi$, $\mu_1$ and $\mu_2$ the indices of refraction from water into glass, and from air into glass. Then, $\sin.\,\theta = \mu_1 \sin.\,PQM = \frac{\mu_1}{\mu_2}\sin.\,\phi$. $DQ = PC + PM = BC\tan.\,\theta + CD\tan.\,PQM = BC$



$$\frac{\mu_1 \sin.\,\phi}{\sqrt{(\mu_2^2 - \mu_1^2 \sin.^2\phi)}} + CD\,\frac{\sin.\,\phi}{\sqrt{(\mu_2^2 - \sin.^2\phi)}}$$

Hence, taking D Q as axis of $x$, and B D produced downwards as axis of $y$, the equation to Q A is $(x - DQ) = y \tan.\,\phi$, and therefore, putting $x = 0$, $y = Db = -\frac{DQ}{\tan.\,\phi}$. Also, if $\alpha\,\beta$ be co-ordinates of A $(\alpha - DQ) = \beta\tan.\,\phi$. ∴ $Db = \beta - \frac{\alpha}{\tan.\,\phi}$ where $\phi$ is found from the equation. $\alpha\,\beta\tan.\,\phi$

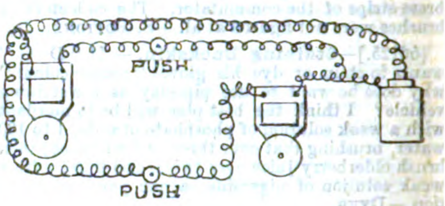
$$= BC\,\frac{\mu_1 \sin.\,\phi}{\sqrt{\mu_2^2 - \mu_1^2 \sin.^2\phi}} + CD\,\frac{\sin.\,\phi}{\sqrt{(\mu_2^2 - \sin.^2\phi)}}$$

$$= \left\{\frac{BC\,\mu_1}{\sqrt{(\mu_2^2 - (\mu_1^2 - \mu_2^2)\tan.^2\phi)}} + \frac{CD}{\sqrt{(\mu_2^2 - (\mu_1 - \mu_2^2)\tan.^2\phi)}}\right\}\tan.\,\phi.$$

If the thickness of the glass C D is neglected, it is seen by a geometrical construction (see Parkinson's "Optics," Third Edition, Art. 73) that the direction A Q is found by drawing from A a normal to an ellipse, centre D, focus B, and axis major, $2\,BD \div \frac{\mu_1}{\mu_2}$. It is clear that the position of $b$ will vary with that of A.—T. H. L.

[56336.]—**Glucose.**—Add to a solution of the substance a few drops of sulphate of copper, and enough solution of potash to form an intensely blue liquid. The oxide of copper is not precipitated in the presence of either of the sugars; but if the blue liquid be very gently heated, a red suboxide of copper will separate if glucose be present; whilst with pure cane-sugar the precipitation does not take place unless the solution is boiled.—A. R., King's Coll.

[56337.]—**Electrical.**—The sketch represents a method of ringing two bells on one circuit with two pushes, and battery at one end. If the circuit is a long one, you may require to increase the battery power.—BOBADIL.

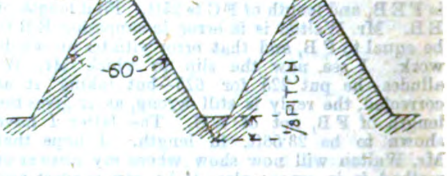


[56340.]—**To Mr. Bottone or Others.**—You would require about 6lb. of No. 16 on the fields, so connected that when a current from a battery is passed through, one pole piece becomes a N. pole and the other an S. The armature is wound in one length: about 6oz. of No. 20 will do very well; the two ends must not be connected together, but each end to its own commutator cheek. One brush must connect to one end of field magnet wire, while the other brush and the other field magnet wire must be attached to binding screws which form the poles of the machine. (See "The Dynamo: How Made and How Used.") You might be able to light seven or eight $2\frac{1}{2}$-candle lamps by driving the machine at 3,000 revs.; but at the end of twenty minutes the machine would become very warm indeed.—S. BOTTONE.

[56342.]—**Public Lighting.**—The town of Enniskillen, co. Fermanagh, is lighted with petroleum lamps placed in the old gas street lamps of the usual shape. This has been the case for the last three or four years, owing to a dispute with the gas company. If I remember rightly, it is the case also in the town of Cavan.—J. R.

[56342.]—**Public Lighting.**—About five or six years ago the Kensington High-street was lit in this way for some months. Perhaps the Kensington or Knightsbridge Vestry would give their experience, on application.—GLATTON.

[56346.]—**Seller's Screw Thread.**—In the American standard screw-thread the sides of the thread are inclined to each other at an angle of sixty degrees, and a part equal to one-eighth of the pitch is cut off the top of the thread, and off the bottom of the space, as shown in the annexed sketch. The following formula gives the pitch of the thread and the diameter at its base, when $p$ = pitch, $d$ = diameter of screw, and $d_1$ = diameter at bottom of thread



$$P = \cdot 1d + \cdot 025$$
$$d_1 = \cdot 87d - \cdot 03.$$

—AREFES.

[56356.]—**Telephone Battery.**—In some telephonic exchanges Leclanché cells are used, being connected zinc with carbon till the required strength is produced. The Leclanché battery consists of a rod of amalgamated zinc immersed in a solution of ammonic chloride, in the outer cell, and a porous cell containing a rod of carbon and a mixture of peroxide of manganese and powdered carbon. This form of battery is very weak, yielding only an E.M.F. of ·31 volt, therefore many cells must be used for heavy work. Daniell's battery is sometimes used, but it is too well known to need description.—J. KEAN, Northampton.

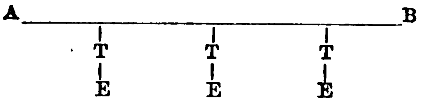
[56356.]—**Telephone Battery.**—When magneto-bells are in connection with telephone, one or two No. 2 Leclanché cells are used for the transmitter. If you do not use magneto-bells, a six-cell Leclanché battery at each station in circuit will meet your requirements, arranging it so as to use the whole battery for outward ringing and two cells for the transmitter.—R. F. S.

[56356.]—**Telephone Battery.**—The battery used is the Leclanché.—Accumulator.

[56356.]—**Telephone.**—The Leclanché battery is commonly used for telephone circuits which are not too constantly used; but where much work is required the Fuller is often substituted. I think that a saturated solution of salt might be used with the zinc in place of sulphuric acid; but should like the opinions of others on the subject; if so, it would not be so "expensive or troublesome."—F. Broadbent.

[56358.]—**Chronic Cold in Head.**—I have seen many cases, having "walked" all the great Continental hospitals for many years, but cannot offer great hopes of a permanent cure. I have seen it cured, however, by the use of cold water injections twice or thrice a day. The advice "Ora et Labora" received—viz., cod-liver oil, iron tonic, and water injections is the best he could have got.—B. Sc., Plymouth.

[56361.]—**Telephone System.**—I find the following arrangement works admirably, and have tried it successfully with as many as twelve stations in circuit:



A B is the line wire, T the telephones, and E earth. In this arrangement only one leading-in wire is required. You must be careful to obtain a good earth at each station.—R. F. S.

[56370.]—**Repairing Boilers.**—There is no great difficulty in repairing a shot hole in a boiler; in fact, the cause for admiration in the case the querist mentions, in my opinion, arises not from the way the repair was made, but from the fact that it was done in the face of an enemy, and under a heavy fire from the Arabs. Repairing shot holes in a boiler is a very simple matter, especially with a boiler for a paddle boat, which always uses steam of low pressure. Now, to put the matter clearer, no doubt the plan adopted was as follows:—The passage of the shot through the boiler plates would mean two jagged holes; through these the steam would rush out pretty quick, so that there would be no need to blow off the steam. Two pieces of wrought iron plate, a little larger than each hole, would then be procured—possibly such odd pieces were carried on board for such use. One piece being held up inside and the other one outside, bolts passing through the two plates would draw them together, and with the aid of cement or red lead and hemp, or any other material handy, a joint could be made—the manhole giving egress to the man holding up inside. I have repaired shot holes in even a ruder way—viz., with thick pieces of timber bolted together; but not in the face of an enemy actually firing on us. Where the point came in, was the coolness of undertaking such a work with most likely few tools and appliances and under a heavy fire. During river fighting, boilers carrying low pressures were repaired in many instances, and the steamer again ready to take her place in the fighting again in a few hours, in the war between the North and South.—Invicta.

[56371.]—**Spoiled Negative.**—Soak the plate for a long time in very strong solution of hyposulphite of soda, which will most likely remove it. I have cured very bad cases in this way; but it is never so good as if the accident had never happened, so take care not to let it happen again. The best way to make sure that a negative is dry is to pass the fingers lightly over it: if it feels shiny all will be right: but if there is the slightest sticky feeling about it, you will print it at your peril. If the hypo. does not remove it, try strong solution of potassium cyanide.—R. A. R. Bennett, Oxford.

[56374.]—**Microscopical—Mounting Sputa.**—Lift the sputa with a glass rod on to the glass slide and put on cover glass by the usual method, then take a clean glass rod and put a drop or two of your staining liquid (Beale's carmine or gentian violet) at the edge of the cover glass, and by capillary attraction the sputa will be stained in a few minutes; it can be ringed with asphalte and will keep for a few days. To make it permanent is more difficult. Frey recommends the addition of camphor water, chromic acid, or Pacini's solution in the same manner as the stain, and later xylol balsam has been used.—B. Sc., Plymouth.

[56378.]—**Launch Boiler.**—The reason why is that the heat from the fire, when first lit, is absorbed by the tubes and the cold water, consequently there is no warm air to cause an ascending current in the funnel. A partial remedy consists in opening the smoke-box door, and by burning shavings, &c., in the box, warm the funnel, and thus set up a primary current. On the smoke-box door being closed, the pull of the funnel will help matters. Another remedy is to start the fire nearer the bridge, allowing a space near the door where the bars are left uncovered. A current of air is quickly set up in some boilers, which, although lengthening the time of getting up steam, prevents the smoke coming out of the fire-door. A friend who has a small launch, and who was troubled in the same way, by my recommendation, got over it as follows: He uses a pair of bellows fitted with a non-return valve in the delivery; this is coupled by a piece of stout rubber pipe to a stop-cock in the steam space. By working the bellows, air is pumped in, and passes out by the ordinary blower-jet in the chimney. The steam space acts as a reservoir of air, and a very little jet at the blower sets up enough draft to keep the smoke passing through the tubes instead of out at the fire-door. Steam is got up much quicker too. Of course, long before there is any steam the funnel and tubes are hot, and the bellows are not needed to force the draught. In the case of a launch in which originally the exhaust was in the funnel, but which was subsequently fitted with a condenser to maintain the draught, an arrangement equivalent to a bellows was worked off the engine to supply air to a large low-pressure jet in the chimney. This also has answered well—Invicta.

[56379.]—**Bichromate Battery for Lighting.**—"In the Dark" must not expect to get the E.M.F. required for his lamp if the cells leak into each other (which reduces the E.M.F. to that of one cell, but gives more current); and I should advise him to buy flat earthenware ones (in place of the old one), or else he can make each cell as follows. Two boxes, one to go inside the other, so as to leave ¼in. at the sides and bottom, which is to be filled up with melted pitch. Two good coats of Brunswick black should now be given inside and outside. The cells should be screwed together and white leaded at the joints.—Accumulator.

[56379.]—**Bichromate Battery for Lighting.**—This battery, besides being wrongly coupled up, has no chance of giving out its best results. In the bichromate battery there should always be more of the negative element than of the positive, and consequently each of your cells will require two carbon plates with the zinc between. This will be 20 carbons for your 10 zincs. In coupling up, begin with, say, the cell on your left, connecting its zinc to the two carbons in the next cell, the two carbons in each cell being joined to each other by a short loop of wire between the terminals. Connect all the cells in this way, the zinc of each to the carbons of the next. This, if correctly done, will leave the two carbons vacant in the cell you begin with, and the zinc vacant in the cell you leave off at. From these you lead the wires to your lamp. Even if properly coupled up, the 10 cells may not light your 10-candle lamp; but the chances of success are increased by using two carbons for each zinc, and the lighting power will then depend on the freshness of the solution and the size of the plates. The cells leaking into each other will not much matter, so long as they do not leak out.—Bobadil.

[56383.]—**The New Station at Birmingham.**—The above station covers an area of 12 acres. There are seven through lines, and several bay sidings. The total length of platforms exceed a mile and a quarter. There are, likewise, five signal cabins, the largest of which requires seven men to attend to.—H. W. Hudson.

[56386.] — **Shuttles, Compressed Teak.**—Answer to queries 1 and 2—best Persian boxwood. Requisites: Colour, toughness, weight. Teak compressed will, no doubt, receive weight and closeness of grain. In a few cases only are shuttles now shod with iron. A few foreign woods are used besides boxwood for the purpose; but we are not quite out of boxwood yet, as there are 2,000 or 3,000 tons in Liverpool at this time which could be bought at a much lower price than in former years. Acout compressed teak taking the place, it—well, we shall see what we see.—Shuttle Maker.

[56388.]—**Motor.**—What battery are you using? If the motor starts all right and slackens afterwards, it is the battery, and not the motor, that is at fault. What *do* you mean when you say, "When the battery-current is divided between the armature and field-magnet, the machine will hardly go at all"? Unless the current does divide itself thus, the motor will certainly not work at all.—S. Bottone.

[56389.]—**Incandescent Lamp.** — Terminology wrong. There is no such thing as a 50-volt lamp. A lamp can have 50 ohms resistance, and require a current of 1 ampere to light it, which will require an electro-motive force of 50 volts to produce, since the current is equal to the electromotive force divided by the resistance. Hence it is impossible to light a single lamp having a resistance of 50 ohms with an E.M.F. of less than 50 volts, just in the same way that you could not expect to melt lead (which requires a temperature of nearly 600° Fahr. to melt it) by holding it in a ladle over a boiler full of boiling water (temperature 212° no matter how big that boiler were).—S. Bottone.

[56389.]—**Incandescent Lamp.**—In the first place, electrical power is measured in volts, the product of the current in ampères by the difference of potentials in volts. The heating in incandescent lamps is proportional to the current squared, as the resistance of incandescent lamps is high; if low difference of potentials is used, the current will be small; hence the heating will be much smaller in proportion, and the lamp will not be incandescent. Evidently, in order to get incandescence, the current must be increased—that is, the difference of potentials must be greater. It is, therefore, evident that the difference of potentials must be great enough to send a current of sufficient strength through the lamps to cause incandescence, and as the resistance of lamps is high numerically, the difference of potentials is much greater than the current.—J. Rance.

[56390.]—**Reamer.**—Our friend "Beginner" is ruthlessly trying, I am afraid, to do an impossibility. Supposing he could get the cutting edge to clean out the hole, it would not be even approximately round or true; and the plan he has tried is useless. It would be far better for him to get the steel blade of the reamer made out to the proper width at once by a smith, and do the job properly. "What is worth doing at all is worth doing well."—Invicta.

[56391.]—**Haydon's Cutter Bar.**—To "Bellicose."—I think I know about Haydon's cutter bar as much as anybody, except himself. I was grieved to hear from a friend some time ago that "D. H. G." (that is, D. Haydon, of Guildford) had been struck down by illness, and was unequal to doing any work. I use his bar constantly for the heaviest cuts, both in the lathe and in the planing machine, and would not be without it on any account. It is, in my opinion, the best cutter bar that I ever saw, and I have seen most, and have made many varieties. The whole thing lies—that is to say, if you have a real Haydon bar (and there have been many spurious ones of improper angle and unsuitable height), in the means applied for grinding. I was the first to suggest this to "D. H. G.," and he condemned my plan utterly at first; but subsequently wrote to say that my method was the only thing wanting to make his arrangement of stock and cutter a complete success. I do not go to the extent that he did of using all kinds of cutters in the bar. I restrict myself to one, or, at most, two—viz., a gouge for wood, with a chisel very seldom, and for metal, say, cast iron or wrought iron, the tool with front angle 120° for roughing out. There is nothing like it that I have ever met with, and with my method of grinding you can go to work in the dark. The last sentence of your query shows that you are in want of more light, which I shall be happy to show you. I explained the grinding years ago, Vol. XIV. p. 434.—J. K. P.

[56391.]—**Haydon's Cutter Bar.**—"Bellicose" should, at any rate, be prepared to conquer the difficulties he meets with in the use of the Haydon cutter bar. Every reader of the English Mechanic will regret, as I do myself, that the well-known initials of "D. H. G." are no longer seen, owing to an illness of the severest character, which, it is to be feared, will permanently incapacitate that clever and practical mechanic, to whom I myself, like many others, owe so much. Hence, as the foster-parent of the cutter bar in question, I feel in duty bound to reply to the above query. At the same time, I am fain to confess that I never succeeded in using the bar to the same extent as the inventor, in whose skilful hands it appeared capable of anything and everything except inside work. It was, however, never intended to be a mere amateur's tool, but to go into the regular workshop, and to bear all the rough-and-tumble of an ordinary tool. It should, therefore, be capable of as deep a cut as a solid tool; and as the principle of the cutting action of the little steel tools is absolutely correct, if they are rightly ground and the bar is rightly made, they should even be capable of a deeper cut than the solid tool shaped and ground by rule of thumb. Were the bars less capable than a solid tool of equal size, "D. H. G." would have chucked it into the rubbish-heap. In order, therefore, to qualify this bar for workshop use, it was necessary to devise a mode of accurate grinding of the cutters at the shop grindstone, with some readily adjustable contrivance which any ordinary workman could make and use. All that is necessary for the purpose is a block of wood to rest across the water trough, or top bars, of the frame, such block being exactly thick enough to give the proper clearance angle to the two lower faces of the cutters; but during this process of grinding the cutter is to be pushed up in the sling, so as to stand above the shank of the bar. Hence it is generally necessary to cut down a little the edges of the water-trough, or bearers, on which the grinding-block is to rest, the height of the latter being found by trial, and the height to which the little tool is to be pushed up in the sling being tested by a steel, or sheet metal, gauge. Once determined, these two measurements are constant for 3° of clearance (the standard), and to get more, or less, clearance, all that is necessary is to push the cutter up a little higher, or to use a thicker block. I may observe here that a common error is to test, not the face angle, but the front edge formed by the meeting of the two lower faces. The latter are to make 3° with the vertical line, not the front edge. Again, the *following* edge is to be so placed as to be nearly parallel with the surface of the work—*i.e.*, as nearly so as will enable it to escape a "hitch in," to which it is liable. If either edge is sharper than the other, it is to be the leading one, not the follower. But as a rule both are of equal sharpness. Observe that the tool is not to be placed "end on," except for a rough cut; and even then it will do far better if the following edge is placed a little towards parallelism with the work. For general sliding a front angle of 120° will be found the best—*i.e.*, a plane angle of that size. I must remind "Bellicose" that if he has merely bought a Haydon bar as he would buy an ordinary tool, without reading up the subject of double edges, so as to understand the principle of the thing, he is sure to get in a fog, and to fail in using the tool to the best advantage. Other bars, such as Tangye's, are excellent in their way, and are now very widely known and used, and with these there is far less trouble in grinding the tools. But Haydon's beats them all when once the principle is grasped, because you can shape the little tools to do any sort of work, and keep the angles of cutting edges, which are both theoretically and practically correct.—O. J. L.

[56393.]—**Cubic Feet of Air per Min.**—9·79815lb. weight of water. Accepting it that 15lb. pressure results from a 32ft. column or head, and, therefore, it requires 166·6ft. column or head to give 50lb. pressure.—G. Pinnington.

[56394.]—**Medical Battery.**—Are they chloride of silver cells? If so, perhaps the chloride requires revivifying, which is done by immersing it in aqua regia. Then charge either with sal-ammoniac or chloride of zinc.—F. Broadbent.

[56400.]—**Harmonium.**—From the wording of this query it seems tolerably clear that the querist is not well acquainted with harmoniums. An instrument 3ft. long might just as well have the regulation 5 octaves, or 61 keys, as 30. To make the reeds would be as profitable as making screws. "Working Man" should buy them, and the pan on which they are to be screwed. He must reflect that to make an instrument with 30 reeds only will mean almost as much work as a full-size 5 octave; and he will always find it more convenient to buy the keyboard, reeds, and pan. He can get a keyboard for, say, 20s., a set of reeds (5 octs.) for 10s., and a pan for 6s. If he will say whether or not he is handy with tools, I will see what I can do to help him; but if it is a question of money, I would advise him to wait until he can afford the full size, for, so far as 30 notes are concerned, he would do better to make it into an organ accordion. The pan for 5 octaves will be about 34in., and he can get that into a case 38in. long: it is not worth while to put 30 reeds only into a case 3ft. long, for 30 reeds will not make what is commonly called a harmonium, and will certainly not give satisfaction as a musical instrument. Directions for making pans have been given many times; but unless the "maker" is a good hand, it is more than likely he will make a mess of it, for 126 thoroughly sound glue joints have to be made in a single-row pan, besides sundry other special points to attend to. By all means buy the pan, the reeds, and the keys; you may try your hand at the bellows and the case. Four octaves, or 49 reeds, is the smallest size that it is worth while to make, and that only for a "portable."—Fliegen.

[56401.]—**Faulty Induction Coil.**—I do not see that steeping the coil in paraffin wax would restore the insulation. I have always found the best way was to rewind at once and thus save both time, temper, and expense, in trying to effect the object by an indirect method. With a new coil the simmering in melted paraffin I believe to be an excellent plan, because it converts the whole into one mass of solid paraffin practically.—Invicta.

[56403.]—**Skrivanoff Battery.**—To "Bobadil."—On referring to my reply you will observe that oxide of mercury is given, not chloride. The red oxide is used. 2. The precipitate formed after boiling is of a light grey colour. The boiling must be continued till the red of the oxide has disappeared, and this cannot be successfully done in much less than the time specified, if you wish to make as much paste with the precipitate as will be of any use. 3. The E.M.F. of the battery per cell is about 1·5 volt.—Bobadil.

The arrangements for electrically lighting the general offices and hotel at Paddington Terminus and the Royal Oak and Westbourne Park stations of the Great Western Railway with incandescent lamps, are nearly completed. The most improved machinery, an enormous mileage of wires, and myriads of lamps, will be employed in the installation, which will probably be the largest of its kind in this country.

# UNANSWERED QUERIES.

*The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.*

Since our last, "Glatton" has replied to 55484.

55871. American Organ.—To Mr. Fryer, p. 527.
55875. Cupola Blast.—To "Invicta," 527.

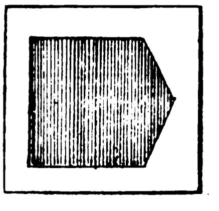
# QUERIES.

[56407.]—**Facing Stop Valve.**—I have an eight-h.p. Robey engine to see to, which does not stop when steam is cut off. I have faced valve to the best of my ability; but still, when steam is cut off, the engine continues in motion. Some engine drivers say there is a joint broke on steam pipe in boiler. Would some kind reader of this useful journal, more experienced than I, give me his opinion as to same, and oblige? I inclose sketch of valve face.—Robey.



[56408.]—**Preparing China for Oil Painting.**—Would some reader tell me how to prepare china for oil painting, so as to look very rough or honey-combed when done?—Constant Reader.

[56409.]—**Sulphur in Coal and Coke.**—Will some one oblige me with a ready mode of estimating percentage of sulphur in coal, coke, and other fuels? I have exhausted every other available source of information in vain.—Innes.

[56410.]—**Finance.**—It is proposed to renew a work at a cost of £700, and it is calculated it would then last twelve years, when it would require renewing again. On the other hand, I calculate, that by patching, at a cost of £316, the work will last six years, when it would require renewal at a cost of £700, and would then last twelve years, as in the first case. What should I save per annum by patching now, and renewing in six years' time, reckoning interest at 5 per cent.?—Sefton Park.

[56411.]—**Power of Electro-Motor.**—I have fitted up an electro-motor, but am not sure my calculation as to its power is correct. Perhaps some of your obliging correspondents will assist me in the matter, the conditions as follows:—The rotating drum is 1ft. in diameter; the magnets are arranged on the periphery; the weight of drum and magnets, 50lb.; the velocity, 220 revolutions per minute. Required, the amount of work done? also the formula by which it is worked out?—R. G.

[56412.]—**Fire for Brazing.**—Would any reader give, with the Editor's permission, a sketch of fire for brazing tricycle frames, also for tempering bicycle springs?—B. M.

[56413.]—**Green's Economiser.**—Will "Engineer, Dewsbury," or other of our correspondents, tell me how to take out a burst pipe, and to put in a new one in Green's Economiser? Please give as full details as possible.—Soho.

[56414.]—**Exhaust Pipe.**—I should be greatly obliged if "Invicta" will tell me of the two remedies he mentioned in last number but one, as I could create a draught as a substitute?—J. T. D.

[56415.]—**Electro-Motors.**—To Mr. Chaster.—Will Mr. Chaster give us a few more particulars of the winding of the F.M.'s of his motor? He says the N. poles of one F.M. must bed against the similar pole of other F.M.; as the whole is fitted up, we must make the poles similar in the winding, as we cannot reverse after fitting up. In winding, I suppose the F.M.'s on the bench in the position they would be when fit up, but resting on the commutator end, then with armature chamber farthest from me, wind on wire same way round as hands of clock, ditto with other F.M., but with armature chamber nearest me, then join end of wire, where I leave off winding in No. 1 F.M., to where I commence on No. 2 F.M.—is this right? Also would he say what position the slit of commutator takes on the spindle?—is it in a line with poles of armature, or with the wire on armature?—J. K.

[56416.]—**To "Invicta."**—Many thanks to "Invicta" for his reply to my query (No. 56040) and shall be very much obliged for any information he can give me concerning the construction of my machinery, also the distance the paddles should be placed from the bow. Would two boilers (the same as on p. 110) be better than one? Would vertical trunk engines do, as they would not take up so much room?—F. C. S.

[56417.]—**Dynamo.**—To Mr. Bottone.—I have wound the dynamo according to your instructions in query No. 55934; when connected, I can only get the current of about one Bunsen cell. I have wound F.M.'s with 9 cores on each leg of No. 18 d.c.c. wire, the weight of which is 5lb. in all, armature with ¼lb. No. 20 wire. I have connected the two upper ends of F.M. wire and soldered them, the lower ends to the brushes. Can you tell whether this is the right way?—P. G., Tooting, S.W.

[56418.]—**Gramme Dynamo.**—Can some of our readers help me out of the following difficulty? I was running my dyname with eight lamps in parallel arc, all working perfectly, suddenly they went dim, and no further efforts would raise them above a red heat. I have carefully examined and tested the dynamo and found it sound, and when a short wire is put between the binding screws, the machine works well, and will rapidly heat it, thus showing that all is right there. It will not, however, light up the lamps when coupled parallel, as it would before, but if a thin wire is put between the terminals and four lamps in parallel arc, coupled up to the bushes, it will keep them burning well. Where is the fault, and why, when all the conditions are the same, will not the machine light up the lamps?—D'Elgo.

[56419.]—**Veterinary.**—Will some pharmaceutical reader elucidate the annexed formula, viz:—

| | |
|---|---|
| Quinquinia, sic: | 16grs. |
| Tinc. nuc. vomicæ | 2drs. |
| Liq. ferri. dialysat conc. ad. | 1oz. |

This is a composition in use by the veterinarians. It is alleged by the druggist preparers to be a mixture of "quinine and solution of iron, which being prepared by a dialysed process, is a neutral and miscible preparation, and will keep any length of time." This clever laboratory rendering is accomplished, and to imitate it I have tried unsuccessfully the several cinchona alkaloids in the tinct. nuc. vom., and liq. ferri. dialy. Would the mother liquor of the quinine manufacturer allow the iron to dialyse, or how is it done?—Army Compounder.

[56420.]—**Waste Oil.**—I have a quantity of waste oil that has been used for an Otto gas engine. Can any of your readers tell me if it is possible to purify it, and use again for the same purpose, if so, by what means?—F. Edge.

[56421.]—**Bichromate Cells with Hydrochloric Acid instead of Sulphuric Acid.**—Will "Sigma," or some other gentleman well acquainted with this matter, inform me whether it is safe to use platinum foil instead of carbon plates in the solution, formed by mixing hydrochloric acid with the solution of potassic bichromate, and if there would be any advantage in the proposed substitution? An early and full answer will be much appreciated by—Bichromate Cell.

[56422.]—**Enamelling.**—To Mr. Lancaster.—I have followed your instructions (54648) page 433, Vol. XL., on the above, but have not been successful in obtaining an even gloss all over the photo., as this must be due to the enamel collodion not being put, which is the best method of coating the glass; also when mounted and trimmed on card with starch, they have a great tendency to curl at the corners? Which is the best mounting medium to use for them?—An Amateur.

[56423.]—**Electro Brazing.**—Could any fellow readers inform me of a good solution for deposition of brass on zinc; also mode and battery power required for working of the same?—Cathode.

[56424.]—**Sheepskin Rug.**—I have bought a white sheepskin hearthrug, and sent it to a professional dyer to be dyed. The wool has been dyed splendidly, but the skin has become as stiff as sheet iron. What can I use to soften it as before it was dyed? It is useless for my purpose in its present state.—Gwent.

[56425.]—**Brass Plate.**—Could any one give me any information how to hammer up a brass plate from a flat piece, and what tools I shall require? The centre has a worked pattern, and I want to dish it and form a flat rim, and wire it round the edge.—Repousse.

[56426.]—**Old Locomotive Engines.**—I have just seen a list, giving particulars of the size, weight, &c., of the following engines: Rocket, Meteor, Comet, Arrow, Dart, Phœnix, North Star, Northumberan (sic), Planet Migestic (sic), Mercury, Mars, Sampson, Jupiter, Goliath, Saturn, Venus, Vutern, Sun, Etna, Fury, Victory, Atlas, Vesta, Milo, Liver, Pluto, Caledonian, Ajax, Leeds, Fire Fly, Torch, Halk, Hecla, Diomed, Shark, Medea. Can any of your readers say to which railway they belonged? I may add that the list shows neither the line, the date, nor the maker, and, but for the fact that the engines are numbered from 1 to 37, I should be inclined to think that they belonged to various lines.—Mac Loco.

[56427.]—**Armature.**—Could some of our electrical readers tell me how to construct a small Gramme ring and commutator, and how to connect the sections for lighting incandescent lamps? A sketch would oblige.—Kernoozer.

[56428.]—**Hot-Air Valve.**—I have a hot-air chamber in which the air must not exceed 103deg. Fahr. I wish to have a valve on top of chamber to relieve the air when it reaches 103deg. Fahr. My plan to lift the valve is to have a lever outside on top of chamber, parallel with the top, working on fulcrum, the valve to be attached to one end, and to the other end of lever a small rod to go down through top of chamber, and connect to a flat rod of metal lying parallel to top of chamber, the lever to be lengthy with bend on the other end, the bend to be fast to the top of chamber. After all have been carefully balanced, I think the heat on rising would draw the inside lever down at one end, at the same time drawing the outside lever down at one end, the other end lifting the valve and relieving the hot air. Would any correspondent kindly tell me if this plan would do?—if so, what kind of metal would be best for the inside lever for the heat to act upon?—G. H. B.

[56429.]—**Mosses.**—Can any fellow reader recommend me a moderately cheap hand-book on mosses, and give me some hints for a formation of a collection of the same?—H. P. Hitchcock.

[56430.]—**Leaky Air-Cushions.**—I have a number of indiarubber air-cushions, but they all leak somewhat. I have tried elastic glue for stopping the leakage, but of no avail. Can any kind reader of the "E. M." assist?—Nimnim.

[56431.]—**Pickle for German Silver.**—Can any of "ours" give me the particulars how to make the above pickle? I thoroughly clean my German silver with oil and brick dust, and then stamp out small shapes in different sizes. I put these away until wanted, and then I find them tarnished, they are too small to clean again I have used weak acid (nit.), which has turned them very bright but they go green after. How can I prevent this, as I experience great disappointment at the dulness of the work?—Max Tour.

[56432.]—**New Midland Engines.**—Will "More Expansion" or "Helvellyn," kindly say why, if these engines were doing so much better through being worked more expansively, they have been taken off the Scotch expresses for the present?—A. Fireman, Lincoln.

[56433.]—**Object Glass.**—Will Mr. Wenham or any other reader give me the radius of curves for flint and crown lens of a ¼in. object-glass for a microscope? I think I have succeeded with the eyepiece, and would like to try my hand at an o.g. I quite indorse the remarks of "Nemo" (No. 24084) in last week's "E.M." I feel sure many amateurs, like myself, would be delighted if such a subject was clearly and simply explained by some of your able correspondents.—Micro.

[56434.]—**Pure Woollen Material.**—What are the tests for distinguishing this from adulterated stuff? Of what is the ordinary blanket composed?—A. C. G.

[56435.]—**Cutting Clock Wheels.**—Will some reader inform me what kind of machine is used for cutting small wheels for clocks? Can they be managed in a hand-turning lathe?—J. Dun.

[56436.]—**Chemical.**—What amount of sulphuric acid 1840 gravity is required to convert 1lb. crystallised Glauber's salts into sodium hydrogen sulphate?—Na$_2$ So$_4$.

[56437.]—**Chemical.**—I wish to start the manufacture of nitric acid, and I shall be obliged if someone will give me a few hints as to the setting of the cylinders with diagram. Are there any books published giving practical details of its manufacture in cylinders? The only books I have seen describe its manufacture in the old-fashioned retorts.—X. Y. Z.

[56438.]—**Fastening Fish Forks in their Handles.**—Will some one kindly inform me how to reset electro-plated fish forks with electro-plated handles, which have become loose in consequence of having been left too long in hot water?—Electro.

[56439.]—**Separating Potash and Magnesia.**—Will "Chemical Subscriber" inform me how to separate a solution of potash and magnesia? I have a large quantity of both, mixed by accident, in a barrel containing some water.—George Richmond, Peckham.

[56440.]—**Warnerising.**—Would someone kindly inform in what this process consists? It is a mode of waterproofing woollen and cotton cloths and lace without altering their appearance or texture.—R. M.

[56441.]—**Sensitive Flames.**—What form of jet is necessary to produce a flame that will respond to certain sounds by suddenly dipping?—W. Hobbs.

[56442.]—**Laminated Armature.**—Will Mr. Bottone kindly send outline sketch, full size, showing proper form of laminated armature 3in. in diameter? What thickness should sheet iron be for this size? How best fastened on shaft? What should be the space between each lamination, and how are they kept apart—by metal washers or non-conductors? I propose to make one of above size for motor. How would discs of malleable iron answer, ⅛in. thick? A thin boss could be cast on each piece to keep them apart, providing the separation may be metallic. Your special opinion on this point will oblige, as well as all the foregoing. Living out of England, I have not access to your book.—Electric Motor.

[56443.]—**Lathe Flywheel.**—Will a cord or gut for a three-speed cone pulley run well enough on an old-fashioned flat-surfaced belt flywheel? I wish to get a new mandrel with all the later improvements, but do not wish to be at the further expense of a new flywheel.—B. Sc., Plymouth.

[56444.]—**Dynamo.**—Could one of our electrical readers tell me how to wind a Victoria dynamo (together with a sketch of the same), and also how is the armature constructed?—Accumulator.

[56445.]—**Driving Sewing Machine.**—I have a No. 1 Wheeler and Wilson sewing machine. I took off all working parts and put on a 3in. circular saw on shaft. I have been using it for a year for grooving, but I find it is sore work to drive it if the cut is deep. I was thinking of putting on two teeth and pinion wheels on it and a handle. Will any of our practical readers give me a rough sketch of how to supply the power?—Joiner.

[56446.]—**Cement for Rain Water Pipe.**—Could any of the readers of the English Mechanic tell me of a cement that would do for an outside iron rain pipe from the roof, where two sections of the pipe are about ¾in. apart? The waste pipe from a bath runs into the rain pipe, so that every time the bath is used it causes the garden to be half-flooded with soapy, steaming water. As it would take a good deal of trouble as well as money to move the pipe, I should be very glad if any one could give me a recipe. Owing to a leakage of the taps there is a continual dropping of water down the pipe.—T. E. Ashworth.

[56447.]—**Pattern Making.**—Many thanks to "J. H." for his kind information. I have only been a subscriber this year and have not got the numbers you speak of; but I have written to the Editor for them. About the back gear spindle, I know how to make it slide out and in by eccentric; but I don't know how to put in the spindle, the holes being oblong, 2 by ¾, and the wheels being bored out to 1¼. If I turn a spindle to fit the wheels, and smaller at each end to receive bushes that go into the holes, then I cannot get it in. What size of driving wheel should I have? My cone on mandrel has three speeds, the largest are 6¾ and 5¼ and 4¼. What should be the size of the steps of driving wheel, so that strap would fit alike on each step?—Busby.

[56448.]—**Double Electric Bells.**—Under this heading, Mr. R. T. Lewis replied to J. James some weeks ago. Would he kindly instruct me how to adjust ordinary trembling bells, so as to make both ring in multiple arc as advised? Those I have are both good bells, coils of silk covered wire, one is a 3½in. bell, the other 4in. They are 250ft. apart, that is the line wire, No. 20 copper, is that length. I have three Leclanché cells connected to them; the porous pots are 7in. deep. Would more battery power be advisable? Why I ask is this; I noticed on some other bells an excess of battery power, caused the platinum contacts to go black—so often wanted scraping. Is the battery power likely to do so in this case? Each bell connected by itself to the cells and line wire rings perfectly, so it is evidently a question of adjustment when they are arranged in multiple arc.—M.M.I.Sc.S.

[56449.]—**Filling Sand Holes in Brass Rollers.**—Will any subscriber be kind enough to inform me how to solder up sand holes or any uneven places which show up after turning large rollers, covered with brass shell, for rolling leather?—Thos. Grey.

[56450.]—**Regenerative Gas Burners.**—Can any of your readers give me some practical information as to the relative advantages of the Wenham, Bowers, and (?) Clark regenerative burners? Do these burners give off excessive heat? Are they fit for a room in a private house? Do they blacken the ceiling, or can they be placed in direct communication with a ventilating tube which goes into a disused chimney? The Bower burner has an arrangement at the under part which will obstruct the light in its passage directly downwards which the Wenham has not, but from what I have seen the Bower gives a whiter light. Any other information about regenerative burners from those who have had practical experience will greatly oblige—Steatite.

[56451.]—**Preparation of Sodium.**—I have lately been trying to make some sodium. I heated strongly sodium carbonate, charcoal, and chalk, in a cast-iron tube, 2ft. long and 2½in. diameter, plugging up the ends with clay, and through one plug passing a piece of iron gas tubing 1ft. long. First a little water came off and then white fumes (CO) which burnt. I then passed the fumes into naphtha for a long time, keeping it cool, but I could collect no sodium. Would any reader tell me why I failed, and how I could do it with the above apparatus?—Perplexed.

[56452.]—**Tennis Lawn.**—Would any fellow reader tell me how to treat my lawn? The soil is very clayey, and it does not seem to come on very well.—Perplexed.

[56453.]—**Paper for Copying Process.**—There is a process of copying in black any number of copies, by means of minute perforations in a prepared paper. Can any reader tell me if ordinary tissue paper will do, and which is the best method to prepare it?—Rustic.

[56454.]—**Violoncello.**—To T. Lisle.—In reply 56300, you described the violoncello by Otto. As I am making a violin as near as possible on the Strad. model, I would like to know the exact thickness of back and belly, as left by Stradivarius while at his best. You will confer a favour by giving the sizes of the two plates all over.—J. Towns.

[56455.]—**Hancock's Inspirator.**—In description of a new American loco. (p. 58, March 20th) it is stated that instead of pumps, the boiler is supplied by a pair of Hancock's Inspirators. Will any reader conversant with the matter, kindly describe this plan, and say how long it is in use, and if satisfactory?—Inspirator.

[56456.]—**To Electrical Advisers.**—I have a battery of six pairs of copper and zinc plates, about 5in. by 5in., in square earthenware jars; using dilute sulphuric acid, the current lasts about a minute and a half only, owing, I suppose, to deposition of hydrogen on the copper plates; amalgamating the zincs has not greatly improved matters. What can I do to utilise the battery with least expense? I have tried to get porous cells, but cannot get any to fit the jars as they are rather narrow. How would bichromate of potash agree with the copper plates?—Friar Bacon.

[56457.]—**Employers' Liability Act.**—Apropos to Mr. Weatherfield's useful information in article 24088 (Employers' Liability Act), and perhaps I may be anticipating his last paragraph in putting the following questions:—Myself and some twenty fellow workmen as millwrights, are principally employed at a distance from our employers' works, in fixing or repairing machinery in corn mills and similar works, for our employers' various customers. With the late improvements, especially in flour mills, of fast-running and complicated machinery, we are invariably working in exceedingly dangerous positions, and in most cases the work is done under the immediate superintendence and order of the mill owner or his manager. Our employers merely send us to our destinations with instructions that we shall find out what is required when we arrive. My further reason for asking this question, is, that during the past week, one of my mates had a most miraculous escape from a serious accident which I witnessed; the work was ordered to proceed with the machinery in motion, though the foreman had been asked to stop for a short time, which he refused. Had an accident actually occurred, who would have been liable?—the owner of the mill, or our employer? or would the owner of mill shield himself by the fact that he did not pay us wages, consequently we are not his servants, and our employers on the grounds that we were not actually working under their instructions?—Bona Fide.

[56458.]—**Crank Bending.**—Will some of "ours" who have had some experience in bending cranks by blocks or other devices, such as are used in looms (they run about 6in. in crank and have rounded corners, and are made from 1½in. round iron) give a fellow-reader a few hints as to the construction of blocks used, and also the kind of lathe for turning inside of crank up? The method described in letter 56127, No 1046, is not practicable in this case, as we have to leave them 3ft. 6in. long over all, and the crank about the middle. It would be impossible to true the crank up without some support in the middle or near the crank.—Young Smith.

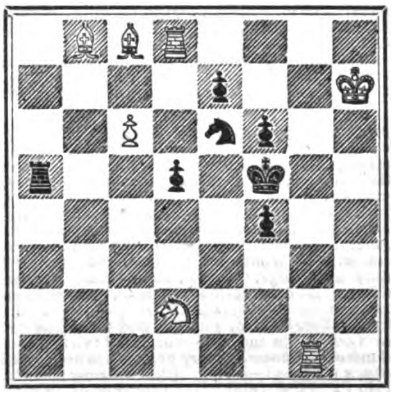
[56459.]—**Burning Oxygen in Hydrogen.**—Would some reader favour me with a description of an experiment, and a sketch of apparatus, showing how a jet of oxygen gas may be burnt in an atmosphere of hydrogen?—Charles Godfrey.

## CHESS.

All Communications for this department must be addressed to J. Pierce, Langley House, Dorking.

### PROBLEM DCCCCXXXVI.—By "Chess Struck."

*Black.*



*White.* [7+7

White to play and mate in three moves.

### Solution to 934.

### NOTICES TO CORRESPONDENTS.

Correct Solutions to 931 by H. Culmer; to 932, by C. Meiklejohn; to 933, by "Birmingham" (no name); J. A. M. (very good problem, but easy); Bronti, Jacobus (though not elaborate, well constructed; several near tries for second solution, but Black neatly escapes); L. S. Chivers (variations must be given in full; not too late for Tourney. The best way to become a composer is to study the problems of the best masters; get Miles's "Chess Gems" and "English Chess Problems," and begin with two-movers); G. J. S. (neat but rather commonplace); J. M. Brown (very good, has some points and is pleasing); J. Sunn, H. Culmer, W. Hewson, E. S., and C. Meiklejohn; to 934, by H. Culmer (but all variations not given); R. A. Bennett (first move difficult, but unfortunately marred by the duals); V. S. Pochin (very cleverly planned); Rev. W. Anderson, Old Romney (but only first move correct, except in one variation).

R. A. B.—Your are wrong as to second solution to 934. If $1\ \frac{\qquad}{\text{Q takes Kt,}}\ 2\ \frac{\text{B-K B 4}}{\text{K-Q 4}}$ and there is no mate.

E. S.—In reference to your attempt, see above notice to "R. A. B."

Double Pawns.—Corrected form substituted.

J. F. P.—Look again at 933.

Correspondents are requested to notice change in address.

The production of coal in Belgium, in 1884, is provisionally put at 18,300,000 tons, against an ascertained production of 18,177,754 tons in 1883.

## ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* Editor *of the* English Mechanic, 332, *Strand, W.C.*

### HINTS TO CORRESPONDENTS.

**1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.**

***** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.**

**The following are the initials, &c., of letters to hand up to Wednesday evening, April 22, and unacknowledged elsewhere:—**

Heaton and Co.—Selig, Sonnenthal, and Co.—Clement E. Stretton.—W. C. Hughes.—Cotton.—An E. M.—Beta.—S. Austel.—W. A. G.—S. S.—Aryas.—J. F.—R. W. J.—J. Broadbent.—Montmartre.—Phillip Vallance.—J. E. Chaster.—Micro.—Electrician.—T. Westlake.—Poser.—B. Boothroyd.—F. E. H.—A. Price.—X. N. X.—D. Booth.—Tubal Kain.—Quantum Libet.—Subscriber.—J. Kean.—J. R. Postlethwaite.

**F. Howard.** (For directions how to make a galvanometer see p. 544, No. 960.)—**Amateur.** (No book that we know of; but many articles in back volumes. See the indices from, say, Vol. XXVII. to the present.)—**One Anxious to Know.** (Certainly, provided it is properly signed and attested. 2. Because the valves were on the dead point, and steam could not get into either cylinder in forward gear. Backward gear allows steam to enter.)—**A Would-be Blacksmith.** (Get "The Smithy and Forge," 2s. 6d., from Crosby Lockwood and Co., Stationers' Hall-court, E.C., and ask them to send you their catalogue.)—**H. D.** (You mean silver, not quicksilver? If so, you will find directions in No. 794. Look in the index to Vol. XXXIV. for a dozen and more references. Every process has been given in the back volumes.)—**W. M.** (Boil a strong solution of soda in it, with the addition of a lump of quicklime. It is much more difficult to get it out of pipes. The easiest way is, perhaps, to take the pipes down and heat them, when the lining will sometimes drop out.)—**Somerset Lad.** (Yes, it is due to galvanic action; the remedy is to make burned joints instead of using solder. 2. See some recent replies. It is not economical, unless it is wanted occasionally only for short intervals.)—**W. H. Searle.** (We know nothing at all of the Cycle Company you mention, and much fear you have lost your money. We should write to the chief constable of the town in which they carried on business.)—**St. Aldates.** (Best thanks, but it is almost impossible to satisfactorily reproduce pencil drawings of astronomical phenomena.)—**X. Y. Z.** (We can hardly insert such queries. You should advertise for tenders for your proposed cottage in the *Building News.*)—**T. H.** (A mere sum, of no value or interest to any one.)—**W. C.** (If you make it in the ordinary way with white flour, it will be as white as you can well get it. You seem to have burnt yours.)—**W. Hobbs.** (See the rules given in the guide books of the game. The opponent must take or be huffed.)—**Tyro.** (See some calculations in last volume, or the formula in the pocket-books. 2. From the Secretary at the office, Gt. George-street, S.W., we suppose. 3. Not suited to the Query columns, because of no interest to any other reader. Must advertise for the loan of the drawings in the usual way.)—**Enquirer.** (They are "cold drawn," or solid drawn as it is called.)—**Anti-Friction.** (See p. 201, Vol. XXXVIII. A good grease is made with tallow 19lb., palm oil 12lb., soda 1lb., water 3 gallons. The proportions vary slightly for summer and winter use. Those for summer are given above.)—**Lewis Carter.** (See Mackrow's "Naval Architects' and Shipbuilders' Pocket-Book," Lockwood and Co., Stationers' Hall-court, E.C. For the designing of yachts, see Dixon Kemp's work, published at the *Field* office, Strand, W.C.)—**Chimes.** (You will find the information in Sir E. Beckett's work, "Clocks, and Watches, and Bells," Lockwood and Co.)—**A. B. C.** (On the principle of the gas-holders, or gasometers as they are called. The quantity can be regulated by a tap; the pressure by weight.)—**Frank.** (Brush it well, and, if necessary, clean with paraffin oil and a brush. Then apply a little linseed oil.)—**D.** (We are not aware that it is usual to enamel them; but no doubt any firm who do bicycle enamelling, nickelling, &c., will undertake the work.)—**G. R. K.** (Query inadmissible. See Hints No. 4. Pictures of the kind are sold by philosophical instrument dealers, such as Horne and Thornthwaite, Strand.)—**Sportsman.** (The usual plan is to run the molten metal through a sieve kept on the shake, and allow it to drop from a considerable height into water. See the cyclopædias.)—**Mso. Jno.** (The usual plan is to rub it over with hearthstone and water.)—**James Barclay.** (A holosteric barometer is practically one which dispenses with fluids, such as the aneroid, the Bourdon or bent tube, and the balance barometer, consisting of a short metallic and a long wooden arm. 2. We do not know where ground malt can be obtained, but imagine it could be had of corn-chandlers or millers, where there is a demand for it.)—**Cyanide.** (Read up back volumes and look in textbooks of chemistry and electricity. A Leclanché battery is quite unsuited for plating.)—**Young Beginner.** (Directions for making cameras have been given many times. See pp. 224, 287, Vol. XXXV.; p. 567, Vol. XXXIII. The common box forms consists simply of two square tubes sliding one within the other. For a portable tripod see pp. 130, 155, Vol. XXXVII. For articles on amateur photography see pp. 212, 381, 474, Vol. XXXVII.)—**Amateur.** (There is a paper on domestic brewing in No. 505, a series of articles in Vols. XVIII. and XIX. on the chemistry of the art, and many replies and letters in back volumes. Black's work on "Brewing," published by Longmans, is about the best, and Lockwood and Co., publish a useful handbook for young brewers by H. E. Wright. You can also have the "Art of Brewing," price 2s., from Mr. Calvert, Great Jackson-street, Manchester, which will perhaps suit you best of all.)

Together with 193,774 useful and valuable articles, worth from One to Two Shillings each, making a total of 200,000 valuable and useful articles to be given to our Subscribers on MAY 15th, 1885, so that each and every one who subscribes before that date will receive THE HOUSEHOLD JOURNAL six months and a beautiful Present besides. The Prizes will be awarded MAY 15th, 1885, full particulars of which will be given hereafter. Subscribers can have presents forwarded to any part of the United Kingdom.

THE HOUSEHOLD JOURNAL Is one of the most BEAUTIFUL and POPULAR MAGAZINES OF THE DAY. It contains Twenty Large Pages, and has an elegantly engraved, illustrated, and tinted Cover. It is replete with beautiful illustrations and choice literature. No expense is spared to make this publication one of the finest in the world.

REMEMBER, WE MAKE NO CHARGE for these presents. The Two Shillings is the regular subscription price for six months to the JOURNAL, and some one is sure to get a Grand Prize of £1,000. OUR PROFIT will come from our advertising patronage, which will be very large, at remunerative rates. We want 200,000 new subscribers before May 15th, and as we are now receiving daily as many as 3,000, we are sure to get the required number. There will be no postponement. Persons wishing to subscribe for a year will receive two receipts for Four Shillings or 52 stamps, entitling them to a year's subscription and two presents.

REMEMBER, we send the JOURNAL direct to your address, post paid, and enclose a numbered receipt for each six months' subscription in the first number you receive.

A FREE SUBSCRIPTION TO YOU.—If you will get five friends to join you, and send us Ten Shillings all at one time, we will send six subscriptions for six months and six numbered receipts, good for six presents. Send Twenty Shillings at one time, with the names of ten friends or acquaintances, and we will send twelve subscriptions and twelve numbered receipts, and so on, thus giving you an extra receipt and subscription for every five subscribers you send in, and each subscriber gets a numbered receipt, and will get one of the presents mentioned above. The JOURNAL is sent, post paid, direct to each subscriber's address you send us.

NOTICES FROM THE PRESS.

"It is an excellent journal of its kind, and is rightly named, for we believe it will speedily find its way into every family circle. The stories, which are illustrated by an artist of superior talent, are written with vigour, and are all-engrossing reading, being full of points that are calculated to hold the reader spell-bound, but at the same time they deviate not in the least from the paths of refinement."—Ilfracombe Observer.

"The 'Household Journal.'—It has started with three exciting serial stories, besides stories, general matter, and illustrations."—Sheffield Daily Telegraph.

"The contents comprise three excellent continued tales, interesting complete stories, instructive sketches and tit-bits, and several poetical pieces much above the average, the whole being tastefully illustrated. The Journal ought to be a welcome visitor in every household."—Wakefield Free Press.

"The 'Household Journal' is replete with high-class tales, poetry, and miscellaneous literature. It is handsome in appearance, and ought to prove a popular household journal."—Christian Commonwealth.

"The 'Household Journal.'—The 'matter' is from the pens of well-known writers, both English and American, and the illustrations are by the best artists. All tastes are catered for, and the 'Household Journal' is in all things what its name implies—a magazine for the home, the family circle, and the fireside hours. The price is 4d., and it is published at 31, Bouverie Street, Fleet Street."—Hull Times.

"The 'Household Journal' is admirably edited, clearly printed, and well illustrated, so that it contains all the elements of success, even with the large number of prizes offered to subscribers. The tales, anecdotes, &c., are capital, and suited to all classes of readers."—Taunton Courier.

TESTIMONIALS.

"Dear Sir,—I received the paper, the 'Household Journal' all right, and was very much pleased with it, and I have got ten subscribers to join me.—Yours truly, THOMAS ARSCOTT, 27, Concrete Buildings, Haverigg Walton, Cumberland."

"Mrs. G. Howlett received the 'Household Journal' yesterday, and is very much pleased with it. She has succeeded in getting five more subscribers, whose addresses she encloses, also P.O. for 10s.—Albert Terrace, Oxford Road, High Wycombe."

"I am so satisfied with it that I wish you to put my name down for another six months' subscription, for which I enclose Postal Order for 2s.—I am, Gentlemen, yours faithfully, GEORGE WILSON, 229, Walton Street, Newington, Hull."

"I may say that your paper far excels all that I have seen, and I wish you every success.—Truly, &c., JOHN WEBSTER, Bull's Head Inn, Upholland."

"Dear Sir,—I hope to send you another six subscribers in a few days. I am highly pleased with the 'Household Journal.' The printing is of a splendid taste, and the literary contents instructive, pleasant to read, and healthy to the minds of both young and old.—Yours truly, D. T. WILLIAMS, Engine Driver, Queen Street, Alltwen, Pontardawe, near Swansea."

"Sir,—I received the 'Household Journal' on the 19th inst., and I am very pleased with it. It far exceeds my expectations. I now enclose £1 for ten subscribers.—Yours, &c., R. E. COLLINS, 37, Picardy Street, Belvedere, Kent.

Thousands of such could be given if space would permit.

SEND MONEY by Registered Letter or P.O. Stamps should not be sent when P.O. can be obtained.
SPECIMEN COPY, 4d.

Address—THE HOUSEHOLD JOURNAL, H. C. Edwards, Manager, 31, Bouverie St.
FLEET STREET, LONDON, E.C.

CUT THIS OUT AND SHOW IT TO YOUR FRIENDS, NEIGHBOURS, AND ACQUAINTANCES, AND PERSUADE THEM TO JOIN YOU, AND THUS GET YOUR OWN SUBSCRIPTION AND RECEIPT FREE. AGENTS WANTED.

## NOTICE TO SUBSCRIBERS.

**Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a Pink Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.**

## CHARGES FOR ADVERTISING.

| | s. | d. |
|---|---|---|
| Thirty Words | 2 | 6 |
| Every additional eight words | 0 | 6 |

**Front Page Advertisements Five Shillings for the first 40 words, afterwards 9d. per line. Paragraph Advertisements One Shilling per line. No front page or paragraph advertisement inserted for less than Five Shillings. Reduced terms for series of more than; insertions may be ascertained on application to the Publisher.**

**ADVERTISEMENTS in EXCHANGE COLUMN—for**

| | s. | d. |
|---|---|---|
| Twenty-four words | 0 | 3 |
| For every succeeding Eight words | 0 | 3 |

**ADVERTISEMENTS in the SIXPENNY SALE COLUMN.**

| | s. | d. |
|---|---|---|
| Sixteen words | 0 | 6 |
| For every succeeding Eight Words | 0 | 6 |

***** It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions; and in cases where the amount sent exceeds One Shilling, the publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O's.**

**The address is included as part of the advertisement, and charged for.**

**Advertisements *must* reach the office by 1 p.m. on Wednesday to insure insertion in the following Friday's number.**

**Every Workman connected with the Building Trades** requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence at 332, Strand, London, W.C.

"THE BUILDING NEWS" is the Principal Journal representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is On Shilling for Twenty-four Words, and Sixpence for every Eight Words after

## TERMS OF SUBSCRIPTION.

### PAYABLE IN ADVANCE.

6s. 6d. for Six Months and 11s. for Twelve Months, Post-free to anypart of the United Kingdom. For the United States, 13s., or 3 dols. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 6d. each to cover extra postage.

Messrs. James W. Queen and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post-free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 6d. each copy, to cover extra postage.

Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX. bound in cloth, 7s. each. Post free, 7s. 9d.
Vol. XL. now ready, price 7s. Post free 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post-free from the office (except index numbers, which are 3d. each, or post-free 3½d.)

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XI. and to subsequent vols., 3d each, or post free, 3½d. Cases for binding, 1s. 6d. each.

**Epps's Cocoa.**—Grateful and Comforting:—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—*Civil Service Gazette.*—Made simply with boiling water or milk, Sold only in packets, labelled—"JAMES EPPS and CO., Homœopathic Chemists London."—Also makers of Epps's Chocolate Essence

**Holloway's Ointment.**—This celebrated remedy possesses unsurpassed healing qualities, relieves local congestions and inflammations and penetrates the pores of the skin to the deeper parts of the body. Chilblains, chaps and chafes of the skin, erysipelas, and glandular irritations are more quickly relieved by it than by any other remedy.

## OUR EXCHANGE COLUMN.

*The charge for Exchange Notices is 3d. for the first 24 words and 3d. for every succeeding 8 words.*

2in. by 3½in. Model Horizontal **Engine**, nearly new, price £4, a bargain.—H. C., 18, Poole's Park, Finsbury Park.

**Working Plan and Details** of 15ft. Launch, 5s. Templates of Frames, 10s.—A. Dorrington, West Gorton, Manchester.

Model Compound Condensing Marine **Screw Engine** Castings, 18s. Litho, 3 stamps.—A. Dorrington, West Gorton, Manchester.

Half horse-power Horizontal **Engine Castings**, ports in cylinders, 12s. 6d. Drawing, 1s. 6d. Litho, 2 stamps.—A. Dorrington, West Gorton, Manchester.

**Engine Castings.**—1 H.-P., 28s.; 2 H.-P., 50s. 3 H.-A., 70s. Litho, 2 stamps.—A. Dorrington, West Gorton Manchester.

Launch **Engine Castings**, 2in. cylinder, 12s. 6d.; 3in., 26s.; 4in., 50s.; 5in., 70s. Litho, 3 stamps.—A. Dorrington, West Gorton, Manchester.

Amateur's **Drilling Machine.** Castings, 3s. 9d. Forgings, 3s. Drawing, 8 stamps.—A. Dorrington, West Gorton, Manchester.

Double or single Oscillating **Paddle Engine Castings** for Boats from 15ft. to 25ft. Litho and particulars, 3 stamps.—A. Dorrington, West Gorton, Manchester.

The Amateur's **Gas Engine.** Complete Castings, 42s. Drawing, 5s. Litho, 3 stamps.—A. Dorrington, West Gorton, Manchester.

Stationary, Marine, and **Model Engine Castings**, List of Drawings and Castings. 1 stamp.—A. Dorrington, West Gorton, Manchester.

**Formulas Worked Out** for winding Dynamos from 10 c.-p. to 500 c.-p., 8 stamps each.—H. Jones.

**Dynamo Castings**, Jones's patent H: 8 c.-p., 5s.; 16, 5s. 6d.; 20, 6s. 6d.; 30, 7s.; 70, 16s. a set.—H. Jones.

**Dynamos**, finished: 8 c.-p., 30s.; 16, 36s.; 20, 40s.; 30, 50s.; 70, 100s. each.—H. Jones.

**Dynamo Armatures** of above wired after fitted up 1s. each, own make, warranted.—H. Jones.

**Dynamos** for house lighting. — Jones's Patent Laminated Felds and Armatures, 5, 6, and 7 lights, £6, £7, and £8 each.—H. Jones.

**Dynamos**, Jones's Patent, 2,122. Trade supplied on royalty. No agents. Motor Castings, 3s. a set.—H. Jones.

**Dynamo Machines Repaired.** Motors, with wire, 5s. 6d.—H. Jones, 48, High-street, Lambeth, S.E.

**Microscopes.** — Apparatus, Alterations, Repairs, and Objectives. R. G. Mason (from J. Swift), Microscope Maker to the trade. All kinds of scientific instruments repaired. Stamp for list.—24, Park-road, Clapham, London, S.W.

A first-class pair **Launch Engines**, quite new, cylinders, 6 inches diameter; stroke, 8 inches; steel crank, &c.; stands 3ft. 6in. high, by about 2ft. 1in. square, on bed-plate, price £60; cost nearly double.—Geo. F. North, 2, Marlborough-place, Brighton.

**Coca Leaves.**—The best and safest stimulant. A magnificent consignment just arrived. Its powers are marvellous.

**Coca or Cuca.**—Sample packet, including medical and scientific opinions, 13 stamps.—Marks and Co., 17, Newcastle-street, Farringdon-street, E.C.

**Chemical Glass-blowing.**—Sprengel and other exhaust pumps. Glass apparatus repaired. Lessons, &c.—Newbold, 25, Calthorpe-street, W.C.

5in. **Mirror**, 52in. focus, 1½ plane, £3 3s.; performance guaranteed.—C. Stocken, 17, West-road, West Ham.

**Battery**, bichromate, highest electrical efficiency. Contains 10 per cent. more chromic acid than potash bichromate. Lee's new double Bichrome. Soluble in own weight water. No crystals formed. Recommended in "E.M." No. 1044 (Reply 56016). 7d. 1lb., 7lb. sample parcels. 6½d. lb. in 56lb. lots.—R. A. Lee.

Chaster's **Electro-Motor Castings**, 3s. 6d. set As described in "E.M.," 1036, 1037, and 1039.—R. A. Lee.

Lee's Patent Primary **Battery** for above, or lighting 5 incandescent lamps. £3 10s.—R. A. Lee, 76, High Holborn London, W.C.

**Hand Dynamos**, £2 10s. each, sent free on receipt of cash.—Sledge, Wyatt, and Co., Clapham.

**Single Needle Instruments** (pedals), with battery, 30s. each.—Sledge, Wyatt, and Co., 95, Wirtemburg-street, Clapham.

**Sounder and Key**, with Battery (P. O. pattern). Complete set, 30s.—Sledge, Wyatt, and Co., Clapham.

Astronomical **Telescopes** of all kinds and Apparatus or Fittings made by A. Clarkson, 28, Bartlett's-buildings.

**Eyepieces.**—Huyghenian of any power to fit any telescope, 15s. each. Sun Diagonals, £1. Star Diagonals, 30s.

Astronomical **Telescopes**, second-hand, by best makers.—Clarkson, 28, Bartlett's-buildings, Holborn, E.C.

**Lathe Heads**, Slide-rests, Beds, Cranks, Rests, Chucks, Appliances, rough or finished. Send for list.—W. R. Smelt.

**Models** for Patentees and Manufacturers accurately made to scale. High-class workmanship. Moderate prices.—W. R. Smelt.

**Turning**, Boring, Planing, Screw-cutting, Pattern-making, Forgings, on customers' own materials. Send sketch for estimate.—W. R. Smelt.

**Price List** of Lathes, Parts, and Castings, 1 stamp.—W. R. Smelt, Engineer and Tool Maker, 7, Goldsmith's-row, Gough-square, E.C.

For sale, a fine **Model Locomotive**, 3ft. 6 inches long by 13½ inches wide, stands 1ft. 6 inches high to top of boiler, all motions from foot plate; it is a powerful and beautifully made engine. Price £70. Photo.—Geo. F. North, 2, Marlborough-place, Brighton.

## EARTHY AND OTHER MINERALS.*

If it is true that the wealth of a nation is indicated by the magnitude of its commerce, it is certain that the prosperity of a country depends mainly on the variety and extent of its natural productions and the manner in which they are utilised. It has been stated that the condition of the "chemical" trade is practically an indication of the commercial condition of this country, and, to a certain extent, the assertion is true; but "chemical" in this connection is a term of very wide meaning, for it includes not only those manufactures which deal with earthy and other minerals, but also those which are more properly designated metallurgical industries. The author of the work, the title of which we give below, has already published a treatise on "Metalliferous Minerals and Mining" (see p. 593, Vol. XXX.); but the present volume deals with a subject of even greater interest, for it describes the earthy minerals proper, then those which are compounds of earths and alkalies, and, noticing at some length such elements as carbon and sulphur, concludes with brief accounts of those metalliferous minerals which are distinguished by the extreme difficulty with which their metals are extracted and the rapidity with which the latter, when unalloyed, unite with oxygen. That, it will be seen, is a tolerably wide field; but though the work makes no pretensions to be a complete manual of mineralogy, it gives a sufficiently full account for those interested in mining pursuits and for the general reader in search of information. The volume opens with silicon, which, in one or other of its combinations, forms the most abundant mineral in the crust of the earth, and shares with oxygen the position of being the principal element of the 64 already known. Silicon combined with oxygen in the proportion of 52 to 48 forms about two-thirds of the crust of the earth, and is known as silica, the base of many more or less valuable natural products. In its pure state as rock crystal it stands high in the table of hardness, being 7 as compared with 10 for the diamond; and though infusible by itself, with soda it melts and forms glass. The behaviour of silica with the alkalies in the presence of heat and moisture has been exhaustively examined by M. Daubrée, and his experiments leave no room to doubt that silica has been dissolved out of the older rocks by the action of soda and potash, in company with water at high temperature, and has been redeposited in the various forms in which it occurs. The commonest of these is clay, a mixture of silica and alumina; the most beautiful those in which the dissolved silica has been mixed with iron, copper, manganese, &c., and under the influence of heat and pressure has become crystallised into transparent forms, more or less pleasingly coloured. The clear white varieties of quartz are pure silica; but quartz is usually either "smoky" or tinged yellow or rose, though nearly all shades of colour are to be found. Divided into the vitreous, chalcedonic, and jaspery varieties, quartz or silica is well known as rock crystal and amethyst; as chalcedony, agate, flint, onyx, &c.; and as jasper, opal, &c. The rock crystal is the material of which pebble spectacles and prisms for optical instruments are made, and the clearest and finest specimens come from Madagascar, where it is frequently found in blocks weighing from 50 to 100lb. The amethyst is quartz coloured with different shades of pale red to purplish blue and violet, owing to the presence of oxides of iron and manganese. Chalcedony ranges in colour from white through grey, green, and yellow to brown, and there are some bluish varieties not unfrequently called sapphire, which consists, however, mainly of alumina, and only about 5 per cent. of silica. In agate the colours are arranged in undulatory and zigzag lines, while the onyx has them in horizontal layers, white, brown, or black. Jasper has the colours in bands, dots, stripes, or flames, while opal is a hardened paste of silica, with from 5 to 13 per cent. of water, milk-white or pearl-grey in tint usually, but possessing a remarkable power of refracting the rays of light, and flashing with a rich variety of colour as the position of the specimen is changed. Silica is most generally associated with alumina—e.g., in the shape of clay; but those two substances combine to give us the more highly-prized gems, with the exception of the diamond, and such useful materials as corundum, emery, tourmaline, and mica. The sapphire is generally composed of 92 per cent. of alumina, with 5 or 6 per cent. of silica, and oxide of iron as the colouring agent; the ruby varies considerably in composition, and frequently contains a large percentage of magnesia; topaz contains from 50 to 60 per cent. of alumina, 29 to 34 per cent. of silica, and a quantity of fluorine; while in the emerald and beryl the proportion of alumina is reduced to about 16 per cent., and glucina in the proportion of about 12 per cent. helps the silica to form the substance of the gems. Pure alumina in the crystalline condition is called corundum; in an impurer state and mixed with other substances it is well known as emery; but it is chiefly because it is the oxide of the metal aluminium that alumina is considered as one of the most valuable of the earthy minerals. The other principal constituents of the rock masses are lime and magnesia, the former being an oxide of the metal calcium, while the latter is an oxide of the metal magnesium. Magnesia is an important component of talc, steatite, chlorite, asbestos, meerschaum, &c., and imparts to those substances the peculiar greasy feel which is well known in the case of steatite and asbestos. The second part of the work deals with the haloid minerals, the most important of which is common salt. Under that heading, Mr. Davies gives an interesting account of the rise and progress of the Cheshire salt-making industry, with a geological section of the country from the Hawkstone Hills to Delamere and Peckforton. The salt deposits of other parts of the United Kingdom are noticed with some detail, and there are useful notes on those of the Continent, and the various methods of obtaining chloride of sodium practised in different parts of the world. Mr. Davies supplies a section of the strata at the famous salt mine of Wieliczka, in Austria, and a page plate of the Hill of Salt at Bahadur Khel, in the Trans-Indus region, with a section through the locality. A short chapter on nitrate of soda, borax, baryta, gypsum, fluor spar, and alum shale is followed by four devoted to that important mineral phosphate of lime, so valuable in the preparation of manures. Commencing with the phosphatic deposit of Canada, the oldest stratigraphically, the author gives an account, illustrated in many cases by sections and diagrams, of the principal known deposits in various parts of the world, from which we learn that, owing to the high royalty demanded by the landowner, English phosphate digging is ceasing to be profitable in Cambridge, Suffolk, and Bedford, and will probably die out in the presence of a cheaper article from abroad. It is satisfactory to reflect that abundant supplies of this valuable, not to say indispensable, manure are available; but the geologist finds much to interest him in the fact that the phosphatic deposits of the Laurentian rocks of Canada and Norway are free from all traces of organic life, while in all the succeeding deposits, except those of Estremadura and Nassau, organic remains are found in abundance. Of all the earthy minerals, however, the diamond is at once the most interesting and the most valuable from the commercial point of view. The diamond is pure crystallised carbon, and is the principal amongst the carbonaceous substances which are classed as earthy minerals. It crystallises in several forms, and is often tinged yellow, green, red, orange, brown, and black; but when pure it is transparent, and is the hardest substance known. De Boordt, in 1607, suggested that the diamond is inflammable, and in 1673 Boyle proved that it is dissipated when exposed to great heat. Lavoisier determined that it is composed of carbon, and numerous experiments since have demonstrated the fact that, chemically speaking, the valuable diamond is exactly identical with a piece of coke. Mr. Davies says it is thought that the diamond is of vegetable origin, having been dissolved and redeposited in some such way as the rarer specimens of silica and alumina, which are known as gems; but on this point there is no evidence at all, and it is far more likely that diamonds are the results of the decomposition of carbonic acid under the combined influence of great heat and pressure. Mr. Davies gives much interesting information in connection with the statistics of diamond mining and the value and ownership of the most noted gems; but, so far as we have searched, has nothing to say about bort or carbonado, which is just at present attracting some attention in our columns. Next to the diamond the most interesting carbonaceous substance is plumbago or graphite, which in its unmixed state is also carbon pure and simple, but it is generally found conjoined with more or less alumina, iron, lime, &c. It is used in the manufacture of the so-called "blacklead" pencil, and blacklead for polishing fire-grates, and, although it is carbon, for the construction of crucibles intended to withstand the most intense heat. Where it occurs in masses it is usually mixed with iron pyrites, alumina, quartz, &c., but like most other minerals, when found in cracks and cavities, where it has been presumably redeposited, is generally pure. In New Mexico it is found in the coal-measures perfectly pure, intense heat having possibly driven off all bituminous matter. Some of the plumbago found in Ceylon only falls short of absolute purity by ·050 per cent. of ash. Jet is another of the carbonaceous substances which has a certain amount of interest, although its only use is for purposes of ornament. A good specimen of Whitby jet contained 79·97 carbon, 13·22 oxygen, 4·30 hydrogen, a little nitrogen and sulphur, and rather more than 1 per cent. of ash. Asphaltum has a higher percentage of carbon, less oxygen and more hydrogen (as a rule), but the proportions vary in specimens from different localities; while mineral caoutchouc, elaterite, or elastic bitumen, is composed mainly of carbon with hydrogen and a little oxygen. Mr. Davies gives some useful notes on the bituminous substances and the distillation of oil from the shales, with geological sections showing the position of the mineral in different localities. Amber is another carbonaceous substance in which the carbon is in the proportion of 72 per cent., with hydrogen and oxygen in equal amounts—viz., 10·5 per cent. It is most abundant on the Baltic coast of Germany,

* A Treatise on Earthy and Other Minerals and Mining. By D. C. Davies, F.G.S. London: Crosby Lockwood and Co.

VOL. XLI.—NO. 1,049.

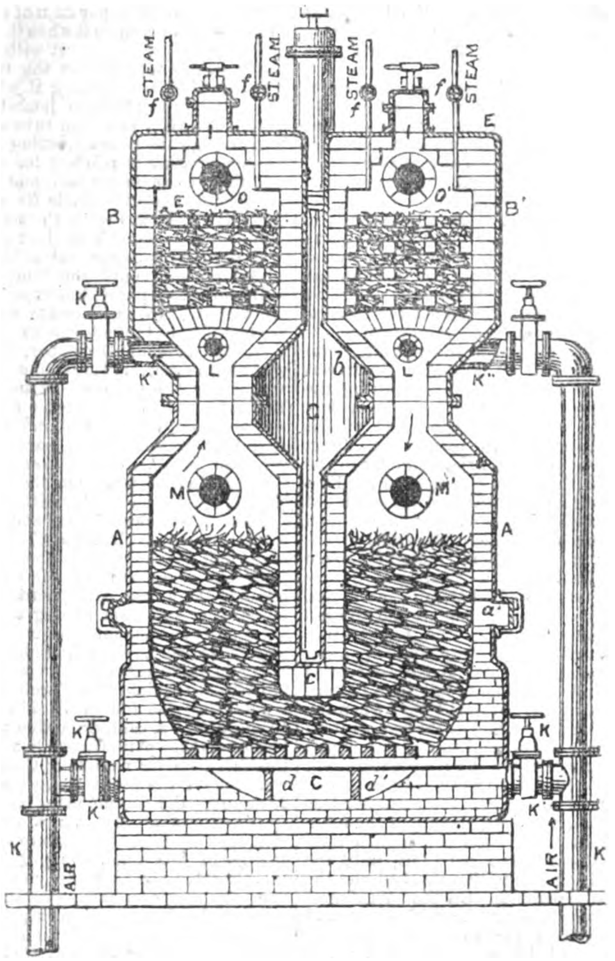
where it is found imbedded in clay of Tertiary age, out of which it is washed by the sea; but it is also obtained direct by digging, some portions of the land in the peninsula of Samland yielding amber at the rate of half a pound to a pound per cubic foot. Amber is undoubtedly of vegetable origin, being a gum which exuded from a class of trees called amber-pines. Sulphur is an abundant mineral in nature, occurring sometimes perfectly pure, or mixed with clay and bituminous substances, but is most extensively associated with the ores of the metalliferous minerals—notably iron and copper. The bulk of the copper pyrites now used in Great Britain comes from Spain and Portugal, the principal district from which the rich mineral is obtained being situated on the boundary line between the two countries. A very good idea of the extraordinary nature of the deposit is given by a general view of the Rio Tinto Mines. The fourth part of the work deals with certain metallic minerals, such as arsenic, cobalt, manganese, &c.; but as they are outside the title of this article, we must conclude with the intimation that, as a companion volume to "Metalliferous Minerals," Mr. Davies's work on "Earthy Minerals" is a useful addition to our library, and may be referred to by the student who wishes to know of what the earth's crust is composed, and in what manner the various substances have been utilised by man.

## TECHNICAL EDUCATION AND THE APPRENTICESHIP SYSTEM.

If any permanent good is to be obtained from the talk about technical education, it is time that some definite idea of what is meant by the phrase should be elicited. Every artisan and mechanic who has "served his time," is supposed to be, and is to a certain extent, technically educated in the rules and methods of his trade; but what is wanted is the technological education of those who are to be the employers, foremen, and workmen of the future—that is to say, they must be instructed in the principles of the processes they are to practise. That is the object of the City and Guilds of London Institute, and if the shorter word "technical" is used in that connection, it includes all that is meant by technological. In a paper read last week before the Society of Arts by Mr. Henry Cunynghame, the object to be aimed at is expressed in a few words:—"We require manual dexterity guided by wide views, and scientific knowledge accompanied by executive power." The technical school cannot therefore take the place of the workshop, nor a technological course of instruction replace the apprenticeship system. In the report of the Technical Education Commission, however, it is recommended that not only should charitable endowments be applied to technical instruction, but even that local authorities should be empowered to establish, maintain, and contribute to the establishment and maintenance of technical schools and colleges—a proposal which is calculated to alarm the ratepayers, especially those who already grumble at the School-board rate. Seeing that the majority of those who form the working classes leave school at the age of fourteen, there will be little spare time to instruct them in even the rudiments of a handicraft, while to supplant the apprenticeship system by technical training, schools may not be altogether profitable either to the pupils or to the trades into which they are to drafted. It is too often said that the system of training in classes is superior to the apprenticeship method, and so it undoubtedly is when compared to those instances in which apprentices were treated as errand boys and allowed to find out just what they could; but that is not what is meant by the apprenticeship system, by the indentures of which an employer or master binds himself to teach "all that art or mystery," &c. It is obviously to the interest of any firm employing mechanics or artisans, to make the best they can of the raw material which comes to them in the shape of apprentices, for their reputation depends on the quality of their goods, or on the manner in which they do their work. It is for that reason so many firms have supported the technological examinations' scheme of the City and Guilds Institute, for they understand that the solution of the problem does not consist in replacing workshop training with classes and lectures, but in supplementing that training by theoretical instruction at the period of life when the mind is most receptive. There is, however, a certain amount of technical instruction, which, if it could be imparted in the school, would be of considerable advantage: we mean that kind of instruction and examination which would discover the bent of the youthful mind, and enable boys to form some idea of their own inclinations. In Mr. Cunynghame's paper, however, we find some useful hints in connection with technical classes and the cost of the scientific apparatus necessary, for which the working classes cannot pay, and the expense of which it would not be fair to inflict upon the public. We quote a portion of the paper dealing with this point, because it will be found useful to many of our readers, some of whom, we are afraid, are not sufficiently aware that the majority of useful experiments can be performed with simple apparatus. "People are not sufficiently aware, because they have not been taught, that as far as the verification of the theory of light goes, such wave-lengths can be measured with all the accuracy that educational purposes require, with a small piece of a visiting card, a piece of fine wire gauze an inch square, and a two-foot rule, total cost, say, 1d. In the same way, a spectroscope can be made out of paper tubes, cheap lenses, a few pieces of glass, and a little bisulphide of carbon, at a total cost of, say 5s., which will divide the D sodium line in a manner quite sufficient for the instruction of mechanics. Instances of this kind might be multiplied indefinitely. There is no scientific instrument of any sort which cannot be made to serve for educational purposes, at a cost of as many shillings as it now costs pounds. But such a mode of study and teaching requires certain rules to be rigorously adhered to. In the first place all lacquer, French polish, ornamental paint, and varnish, must be strictly discouraged, and even forbidden. The students must be taught not to spend one moment on ornamentation of any kind. The one aim must be accurate fit and adjustment of essential parts, and absolute indifference to all others. This rule is harder to enforce in practice than might be imagined. When a new microscope comes home from the maker's, its polished mahogany case is opened, and to the eyes of the beginner, a vision of splendour is revealed in the golden gleam of the shining lacquered brass. All this he must studiously avoid. It is the mere joy of a child in a new toy. His only care or thought ought to be whether the lenses are optically true and achromatic, and, with these conditions satisfied, he should be carefully weaned from the prejudice in favour of varnish and veneer. . . . The first benefit of the adoption of the system of making the students construct their own apparatus is, therefore, economy. All that is needed is a store of flat glass, glass tubing, wood of different sizes, brass discs, screws, wire, and various chemicals, and a few simple tools, such as a fine tenon saw, pliers, and a few files, while, for general use, a glazier's diamond, a grindstone, and a large dividing protractor, and steel scale, a pair of accurate balances, and a few such apparatus, should be in every laboratory. . . . On the table I have here a set of tools and chemicals with which many of the apparatus here before you were made, and which is amply sufficient to make all that are given in the list. The cost of the whole comes to £6 10s. In this way a sum of £20 would go far to set up a technical class with the necessary tools and appliances, while if it were desired to do more elaborate work, the addition of a lathe, bench-vice, set of drills and other simple tools could be made for about £60. But not only is economy consulted by this system of teaching: the instruction is far more efficient. Suppose, for instance, it be desired to exhibit the qualities of polarised light. Whether will it be better to buy a shop-made polariscope with all the adjustments already made, or to cause the student to place his reflector at the true polarising angle, to secure it there with neat pieces of cork and sealing wax, to place his bundle of microscope glass plates in a tube; again securing the proper angle of inclination, and to tinker up the instrument till it works, at an outlay for materials of, say, a shilling? Which of two students will use a really fine instrument the best?—one who has been trained in the manner here advocated, or one who has always been provided with instruments ready made?" In concluding his paper, Mr. Cunynghame said:—"To attempt to do, at public expense, what can only be done in the workshop, is a mistake: it will fail in its results, and it is unjust to expect the nation to pay for it." There is abundant means in this country for the technical or technological education of the masses, and the problem is not so much how to do it, as to how to do it cheaply. With regard to the apparatus exhibited by Mr. Cunynghame, Prof. Guthrie said the author had spoken too slightingly of some of the instruments, for in Prof. Guthrie's opinion such apparatus as was shown was far more scientifically and absolutely accurate than that which would be produced by the ordinary optical instrument maker. It was simple in construction, but truthful in conception, and without any adornment. This method of bringing the hand and the mind to work together really lay at the basis of all true technical instruction; where the mind alone was employed, the knowledge acquired passed away; but when the mind and the hand had been educated together, the knowledge was never forgotten.

## THE MANUFACTURE OF ILLUMINATING AND HEATING GAS

Many processes for the manufacture of gas from water and its subsequent enrichment with hydrocarbons have been described in back volumes, but at the present time the United States seem to have a monopoly of new inventions in this connection, probably owing to the high price there charged for the ordinary coal-gas. Mr. Boult, of High Holborn, has recently patented in this country, on behalf of John Hanlon, of New York, an improved method of making illuminating and heating gas, the invention being more immediately connected with that process and apparatus in which steam is decomposed and bituminous coal is distilled in the same cupola or generating furnace; in which hydrocarbon oil is vaporised either in the generator or in a connected fixing-chamber which is heated by the waste gaseous products of combustion of the fuel in the generating-chamber; and in which the resulting gases and vapours are combined and converted into a fixed gas in the heated fixing-chamber. The object of the invention is to improve the manufacture of illuminating gas by so conducting the operation as to effect a great economy in the use of hydrocarbon liquid by which the gas is carburetted, that is, to prevent destructive decomposition or reduction to lamp-black or solid carbon, and consequent waste of the hydrocarbons which impart the illuminating quality to gas. Another object is to improve the apparatus in such manner as to better preserve the grate bars from the destructive action of steam and hot gases; to simplify and improve the coal-charging apparatus; and to provide a superheater so constructed and provided with discharge-pipes and valves that the carburetted gas may be discharged immediately upon being fixed, whereby injuriously long exposure of the hydrocarbons to a large body of heated refractory material is avoided, and gas of more uniform quality and candle-power is produced. The illustration represents the generating and steam superheating chambers in vertical section. The generating apparatus G is composed of two furnaces or chambers, $A\ A^1$, connected by a common base and freely communicating with each other above the grate C, which is common to both; and they are surmounted by steam superheating and decomposing chambers, $B\ B^1$, connected by the necks $b\ b^1$. The generators and superheaters are constructed of fire brick, covered by jackets of plate iron, and mounted on a brick or stone foundation. The decomposing chambers, $A\ A^1$, are represented as independent structures, slightly separated from each other down to near their bases, a short distance above the grate—each having a distinct inclosing wall and jacket down to the arch *c* above the grate chamber, but it is obvious that they might both be built in one structure, inclosed in a common wall and covered by a single jacket, and separated by a division wall resting upon the arch *c*: this division wall might be strengthened and made tight by a central iron plate. The chambers, $A\ A^1$, have their bottoms curved and sloping from their outer sides down to the bottom of the ash-pit, in order to reduce the grate surface, and so that the chambers may be more readily cleaned. The ash-pit is divided into three separate compartments by the partition walls, $d\ d^1$, extending from front to rear thereof, so that the gases from



from one generating chamber are not allowed to pass down through the grate, and thereby corrode and burn it out, but are compelled to pass above the grate to the adjoining generating chamber. Tight-fitting doors, *a*, close passages into each compartment of the ash-pit. The steam superheating and decomposing chambers, B $B^1$, are connected with the generating chambers by contracted necks, *b* $b^1$, and have near their bases arches of masonry supporting the cellular brickwork, E $E^1$, and iron scrap; they are also provided with short smoke stacks or passages, I $I^1$, having tight-fitting lids or caps; these passages also serve as man-holes, to give access to the chambers for the purpose of laying, repairing, and cleaning the cellular brick-work. Steam-pipes having valves, *f*, are connected with the top of each superheating chamber. A coal-charging hopper (not shown in the figure) connects by a chute with the upper portion of each generator, and the hopper has at its bottom a water-cooled valve, provided with a stem and operating lever. The conical portion of the hopper is constructed of sufficient size to hold a single charge of coal, and this chamber is separated from the main fuel chamber by a cut-off slide, constructed with separated bars like a grid-iron. The fuel chamber should be made large enough to hold a number of charges of coal, and it is closed at the top by a tight-fitting lid. An air-blast pipe, K, connects by branch, $K^1$, having valve, *k*, with the base of each generating chamber below the grate, and by a branch, $K^{11}$, having a valve, $k^1$, with the base of each steam superheating chamber. A sliding oil supply pipe (not shown in the figure), having a pivoted operating lever, passes through a stuffing-box and sleeve near the base of each steam superheating and decomposing chamber, to supply oil for enriching the gases passed from each generating chamber. When oil is admitted the supply-pipe is projected some distance into the chamber, in order that the oil may drop freely through the passage in the neck, *b* or $b^1$, down into the rising and outgoing current of hot gas. Each generating chamber is provided with a number of openings, $a^1$, closed by tight-fitting caps; one set just above the grate bars, and another set higher up, for the insertion of bars to break up the coal or coke, and break down the clinker. Gas discharge-pipes, M $M^1$, having water-cooled valves, connect near the tops of the generating chambers, A $A^1$, and with vertical stand-pipes (not shown). Pipes, M $M^1$, are for the escape of gases resulting from the decomposed steam, coal, and oil on their way to the fixing-chamber, and also for the escape of products of combustion. The superheating and decomposing chambers have, connecting near their tops, the outlet-pipes, O $O^1$, having water-cooled valves leading to the stand-pipes, for the escape of products of combustion. The stand-pipes connect at their lower ends with the base of the fixing chamber. The lower ends of the stand-pipes, from just above the connecting-pipes, M $M^1$, downward, and where they are exposed to the greatest heat, are lined with fire brick, while the upper ends, through which but a small proportion of hot products pass, are simple iron pipes. The fixing-chamber is constructed of firebrick, covered with a tight jacket of plate iron, and is mounted on a brick or stone foundation; it is provided near the base with a perforated arch for supporting the cellular brickwork filling. This brickwork is separated into three sections or bodies by intermediate spaces, and at each space, above each body of brickwork there connects a gas eduction-pipe leading to the hydraulic seal-box. An air-blast pipe, having a valve, connects with the base of the fixing-chamber below the arch, for supplying air to produce complete combustion of gaseous products from the generator while heating up the apparatus. The two generating chambers are operated reciprocally, the superheated steam being passed alternately down into one, and the resulting gases up through the other, while the fresh charge of bituminous coal is also distilled alternately, first in one and then in the other chamber, but always being freshly charged into that chamber least highly heated, and up through which the gases are passed on their way to the outlet-pipe and fixing-chamber. A fire is first kindled on the grate, and it is urged by air-blasts admitted through pipes, $K^1$, by opening valves, *k*, on each side of the grate, while fuel, preferably anthracite coal, or coke, is gradually fed in, till a bed of highly-heated or incandescent fuel, several feet thick, is formed in each chamber. During the admission of the air-blasts below the grate, the cap of smoke stack is open, and at first the valves on outlet pipes, M $M^1$, are opened for the escape of products of combustion into fixing-chamber; then, as the beds of fuel increase in the generators, and carbonic oxide is given off, air is admitted to the base of fixing-chamber, for causing complete combustion of the hot carbonic oxide, and thereby heating the refractory brickwork in the fixing-chamber. Near the end of the operation of heating up, air-blasts are admitted by branch pipes, $K^{11}$, into the bases of chambers, B $B^1$, for burning hot products therein, and heating the contained brickwork and iron scrap. The beds of fuel in the generators being raised to incandescence, and all the chambers being properly heated, the valves of the air-blast pipes are closed, and other operations having been performed, steam is admitted by pipes, *f*, into the top of superheating-chamber, B, where it is superheated and partially decomposed by passage down through the highly-heated brickwork and iron scrap contained therein, and the resulting hydrogen and superheated steam are passed down into the incandescent fuel in chamber A, where decomposition is completed: the resulting gases passing below arch, *c*, and above the grate up through the hot fuel in chamber, $A^1$, where any carbonic acid present is converted into carbonic oxide. The partitions, *d*, $d^1$, in the ash-pit prevent the current of gases from passing through and below the grate, whereby it is preserved from corrosion. About the time that steam is admitted to superheater, B, a charge of bituminous coal is dropped upon the bed of hot fuel in chamber, $A^1$, so that the gases resulting from the steam are passed up through the distilling charge of coal, and thereby combine with the rich hydrocarbon vapours, and carry them into the fixing-chamber. If a rich gas is desired for illuminating purposes, hydrocarbon oil is admitted by pipe into chamber $A^1$ where it is vapourised, and the vapours mingled with the outgoing gas pass through pipe $M^1$, to the fixing-chamber. If the heat in chamber $A^1$, is so great as to be destructive of the oil, it may be admitted at any desired point in the stand-pipe, or even into the fixing-chamber, for carburetting the gas. It is intended, however, that the generating-chamber in which coal is last fed, and up through, and out of which the gas is passed, shall not be at such high temperature as to change the hydrocarbons of the coal, or the liquid, into lamp black or hard carbon. The large volume of hydrogen entering from the adjacent chamber assists materially in carrying the hydrocarbons forward, and preventing them from burning. The iron, which is oxidised by the passage of steam through it, is revivified by carbonic oxide, the steam and gases being taken in the reverse direction, the alternating processes forming part of the claim in the patent.

## DR. HENRY DRAPER'S EXPERIMENTS ON THE USE OF CARBON BISULPHIDE IN PRISMS.[*]

THE photographs which were taken in the research on the presence of oxygen in the sun, in the earlier as well as in the later series of experiments,[†] were obtained by the use of two hollow prisms filled with carbon bisulphide. These prisms were loaned for this purpose by Mr. Rutherfurd, having been made by him for producing his celebrated solar prismatic spectrum. The photographic work for the oxygen research was done in New York in a back room of the third story of Dr. Draper's residence. The temperature of this room proved to be remarkably uniform, the quality of the photographs, and especially the sharpness of definition, being all that could be desired. When, however, the preliminary experiments required for the continuation and extension of this research were undertaken in the new physical laboratory (which Dr. Draper had built above his stable in the rear of his house, and which was completed in 1880) it was found practically impossible to use carbon bisulphide prisms in this room owing to the rapid variations of the temperature there. No definition whatever could be obtained with the same prisms which had performed so well in the main house. In consequence, the use of these prisms had to be abandoned and a series of experiments was made to obtain the spectrum by other means. First a Rutherfurd silvered glass grating of 8,640 lines to the inch was employed, and subsequently a train of six flint-glass prisms made by Steinheil and loaned by Mr. Rutherfurd. With reference to these experiments, Dr. Draper says: "The exposures required when using the silvered grating were so long that experimentation was very tedious; but when, in addition, the definition did not equal that of the two bisulphide prisms formerly used, a change became necessary. If we could overcome the effect of temperature on bisulphide it would doubtless serve our purpose best, because it is more transparent, less coloured, and loses less light by reflection than glass prisms, since there are only two prisms needed to do the work of four flints. But the instability of a bisulphide train is so marked in the new laboratory on account of the fluctuations of temperature that we have not been able to depend upon it. Possibly, if the prisms were inclosed in cotton batting, or immersed in water, these difficulties might be overcome."

---

[*] From the *American Journal of Science*.

[†] The results which were obtained by Dr. Draper in his investigations on the cause of the difficulties encountered in the use of carbon bisulphide in prisms seemed so valuable and so likely to be of service to others engaged in photographing the prismatic spectrum, that at the suggestion of several of his scientific friends it was decided to publish them. At the request of Mrs. Draper, therefore, and with her kind assistance, I have collected from Dr. Draper's copious notes the facts in relation to his experiments which are detailed in the following pages; and have also made some supplementary measurements to test the efficiency of the apparatus.—GEORGE F. BARKER.

With the flint prisms, the definition of the sun spectrum was excellent, but it was found impossible to get the line H on the photographic plate through the train. The silvered glass grating permitted the spectrum from F to a long distance above H to be obtained at one exposure on an eight-inch plate; but the definition given by it on the sun spectrum was inferior to that obtained with the prisms. The definition of the flint train, however, good as it was, only equalled and did not surpass that of the bisulphide prisms used in the oxygen research; "the rippled line below G is as well defined," Dr. Draper says, "as I have ever seen it with the two bisulphide prisms." On the spectrum of the carbon arc, the dispersion given by the train between G and H was double that given by the silvered grating in the spectrum of the first order; while that given by "the two bisulphide prisms between G and H is slightly greater than that of the six flint prisms." Moreover, while the definition on the lines of the sun spectrum was best with the flint prisms, that on the spark spectrum lines was best with the grating. These experiments extended through nearly two years, from March, 1880, until early in the winter of 1881-2.

Among the earliest experiments which were undertaken in the new laboratory was a series made to test the performance of a bisulphide prism of Thollon's construction, made by Hilger, of London, and obtained from him by Dr. Draper when in Europe, early in 1879. This prism consists of a glass bottle having two plane sides making an angle of 90° with one another, upon which are cemented two prisms of flint glass four by two inches on the face, having each a refracting angle of 18°. The refracting edges of these glass prisms are opposed to that of the bisulphide prism. Hence the refracting angle of the compound prism is 54°. The same difficulties were experienced with this prism as with the Rutherfurd bisulphide prisms. Owing to the temperature variations, the spectrum lines were "woolly," and no definition was possible. Dr. Draper says: "The bisulphide prism touched with the finger or breathed on loses all definition at once." It was found, however, that the dispersive power of the Thollon prism was equal to that of about four of the Steinheil flint prisms; and this fact, together with the unsatisfactory character of the results obtained with the train of prisms as well as with the grating, led Dr. Draper to undertake an investigation into the causes of this unsteadiness of the bisulphide, with a view to remedying it if practicable.

The same difficulty has been encountered by all experimenters who have endeavoured to use bisulphide prisms. Mr. Rutherfurd himself found it to be very serious, and M. Thollon says such prisms must be protected carefully from temperature variations. It was while using these prisms that Mr. Rutherfurd made an important observation. He noticed that "if a good prism which, with a high power, refuses to define the soda line (a more stringent test than solar lines) is violently shaken and then placed in position, it will for a few minutes define beautifully, but gradually settle into its former condition. It occurred to Dr. Draper, therefore, that possibly the striæ caused by convection currents produced by inequalities of temperature, and which caused the bad definition, might be destroyed by an active agitation of the liquid. Acting on this suggestion, on the 19th November, 1881, he placed a small propeller wheel in the bisulphide contained in the Thollon prism, its shaft passing out through the stopper. By means of a small electric motor, this propeller could be rotated with any convenient speed. The result was marvellous; by thus keeping the liquid in agitation all inequalities in its density were prevented and the definition became excellent. On the 21st November, with the stirrer revolving five times a second, the definition was so perfect that even with a faint flame the sodium line could be seen distinctly reversed. A series of comparisons was now undertaken between the train of Steinheil prisms and the Thollon prism as arranged with the stirrer. On December 2nd, using sunlight, the relative dispersion of the two was found to be very nearly equal, the flint train giving perhaps one-eighth more; but the amount of light transmitted by the bisulphide prism was at least four times and in the region about G eight times as great as that obtained from the Steinheil prisms.

But now another source of error was developed. Although when the propeller was running the definition of the bisulphide prism was not affected by changes of temperature, yet now these changes of temperature, by changing the refractive index of the liquid, caused a continual shifting of the position of the lines in the spectrum, either in one direction or the other. It is obvious, therefore, that during an exposure of any considerable duration, such as is often necessary with faint spectra, this change of position in the lines due to temperature change would absolutely destroy the definition on the photographic plate. In the hope of correcting this new difficulty, an even temperature box was constructed about the prism, and was filled with cotton. On the morning of December 8th it was found that the thermometer had fallen during the night 9° F., and that the sodium lines had shifted toward the more refrangible end of the spectrum a distance of 0·75 inch.[*] A direct experiment, made by placing a thermometer in the bisulphide, showed that for a change of 3·75° F. a change took place in the position of these lines of 0·375in. The box containing the prism was then enlarged to 30in. on a side and a plate of iron 6in. square was let in to the bottom, and so arranged that it could be heated by a gas flame. Subsequently an iron tube closed at the upper end and 9in. long was passed through the plate and allowed to project 7in. into the box. The temperature within was regulated by two compound expansion bars made of strips of vulcanite and brass riveted together and included in the circuit of a battery and an electromagnet so arranged that when the ends of the bars came in contact as the temperature rose the circuit was closed and the electromagnet turned down the gas. When the temperature fell, the circuit was opened and the gas was again turned on. On the 16th of December the regulator was adjusted for 77° F., the temperature of the room being 63° F. After four hours the sodium lines ceased to move towards the red; but, until the stirrer was started, the definition was bad and the lines could not be separated. On the morning of December 20th the thermometer in the box had fallen over night from 79° to 65° F., and the sodium lines had receded toward the violet end of the spectrum a distance of 1·375in. On turning on the heat, the prism did not appear to feel the effect for half an hour. Then the lines began to move toward the red end of the spectrum and continued to do so for more than five hours. On turning off the heat, the lines began to recede in half an hour; but although it was again turned on, they did not become stationary for an hour. On the 23rd the even temperature box was enlarged and a second box constructed within it, the space between the two being filled with cotton. On the 29th the regulator was started at 7 a.m. At 1 p.m. the temperature became stationary at 70° F., and the spectrum remained at rest for two hours. On the morning of January 1st, 1882, the temperature of the box was 54° F., having cooled from 72° F. over night, and the sodium lines had moved a distance of 1·8in. From these experiments, the conclusion was reached that if a change of over 10° F. is to be made in the box, it is doubtful whether with this apparatus the spectrum can be made stationary on the same day. The heat was, therefore, left on over night, and the temperature was found to be readily controlled the next day. There were fluctuations of course, but they were not enough to injure the definition if the exposure was not over 15 or 20 minutes. On the 25th of January some changes were made in the heating tube by placing a funnel upon its lower end, by continuing it up through the top of the box, and by making an opening on one side of it within the box. A relay was also arranged with a damper so as to close the top of this tube whenever the circuit was broken by the separation of the differential bars in the box, and to open it when the circuit was closed. This relay acted in concert with the electromagnet above mentioned, closing the tube when the gas was turned on and opening it when it was turned off. On lighting the gas jet below the funnel, the heated air rises into the tube and passes into the box through the lateral opening in the tube. When the temperature is reached for which the bars are set, they come in contact and close the circuit. The electromagnet attracts its armature and thus turns down the gas while the relay also closes, and thus opens the damper on the top of the tube. The heated air now passes out of the box through the lateral opening until the temperature has fallen sufficiently to separate the expansion bars and open the circuit. No experiments with this apparatus are recorded in the note-books.

On the 27th of December, 1884, the apparatus was put in order, and some experiments were made with it for the purposes of testing its efficiency. The automatic arrangement for regulating the heat was easily adjusted and found to work well. The definition of the sodium lines, which at first was very bad, became admirable in a few moments after starting the stirrer. On the 30th the first systematic test was made with it. The gas was lighted at 9 o'clock a.m., and at 11h. 20m. the temperature of the box was 67·5° F. The cross wires of a small telescope were then set on the less refrangible component of the sodium line. In 15 minutes the other component was on the cross wires, the spectrum having shifted the distance between these sodium lines in this time. The displacement was toward the red, and the prism was rising in temperature. The second similar change in position required also 15 minutes; but the third required 19, the fourth 35 minutes, and the fifth 49 minutes. A centigrade thermometer reading to tenths was then placed in the box. At 5h. 20m. p.m. this thermometer read 21·3° C., and the cross wires were set on the less refrangible sodium line. In 25 minutes the thermometer read 21·4° C., and the spectrum had moved over a little more than the distance between the components. A second change of this amount required 41 minutes, the thermometer showing no change. At 1h. 2m. a.m. the spectrum had again shifted by a distance equal to that between the components of the sodium line, but had required 97 minutes to accomplish it, the thermometer reading 22·3° C. at the beginning and at the close of the experiment. The latter part of the time the spectrum shifted by only the width of one of the components in an hour. In a second experiment an hour and six minutes was required for this amount of displacement. The thermostat was then left in action over night. At 9h. 10m. the next morning the thermometer read 22° C., not having perceptibly changed since the last reading, while the sodium lines had shifted in seven hours by only a little more than the distance between them.

The gas was then turned off and the entire apparatus allowed to remain at rest for several days, the temperature of the box, the position of the sodium lines, and their definition being observed by Mrs. Draper from time to time. The following are the values obtained:—

| Date. | Time. | Temp. of Room. | Temp. of Box. | Definition. | Displacement. |
|---|---|---|---|---|---|
| Dec. 31st. | 10 p.m. | 68° F. | 18·2° C. | Excellent. | 1·25 inches. |
| Jan. 1st. | 12 m. | 69° F. | 18 4° C. | " | 1·166 " |
| " | 3 p.m. | 68° F. | 18·6° C. | " | 1·083 " |
| Jan. 2nd. | 10.45 a.m. | 56° F. | 13·0° C. | Good. | 2·416 " |
| Jan. 4th. | 12.30 p.m. | 50° F. | 9 6° C. | Fair. | 3·583 " |
| " | 4.40 p.m. | " | " | Excellent. | 3·583 " |
| (*Gas lighted in thermostat.*) | | | | | |
| " | 7.30 p.m. | 50° F. | 15·2° C. | Entirely gone. | 2 083 " |
| Jan. 5th. | 10.25 a.m. | 50° F. | 9·4° C. | Excellent. | — |
| (*Gas lighted in thermostat.*) | | | | | |
| " | 10.30 a.m. | 50° F. | 10 2° C. | Fair. | — |
| " | 10.45 a.m. | " | 10 9° C. | Bad. | — |
| " | 10.55 a.m. | " | 12·2° C. | Entirely gone. | — |
| (Started the motor and in five minutes the definition was good. Put out gas and a few minutes later stopped the motor. Definition lessened very slowly.) | | | | | |
| " | 11·15 a.m. | 50° F. | 11·2° C. | Entirely gone. | — |

The results which have been given in the preceding pages seem to have a two-fold bearing. In the first place they prove that by the simple expedient of stirring the liquid in a prism by means of a propeller or other device, so as to keep it in active motion, all striæ due to temperature changes may be prevented and the definition rendered perfect. Even carbon bisulphide, whose extreme mobility and high expansion-coefficient make it extremely sensitive to variations of temperature, may be made in this way to give the most admirable definition; so complete, indeed, that in the spectrum given by such a prism a fine reversed line has been seen in one of the components of the sodium line. The practical value of this simple device is very considerable. The Thollon bisulphide prism above mentioned, while giving 7-8ths as much dispersion as six flint prisms, gives four times the light in the entire spectrum and eight times the light in the region near G. For photographic purposes, now that the definition can be made permanently sharp and the shifting prevented, this prism must replace trains of glass prisms, and even gratings unless these are of large size and are used with telescopes of proportionately large apertures.

---

[*] These measurements were made by Mr. C. D. Chapman, who at that time was acting as Dr. Draper's assistant.

In the second place this investigation has called attention in a very marked manner to the change in refracting power with change of temperature. This subject has already been discussed with reference to liquids by several authors, especially by Gladstone and Dale in 1858, and with reference to glass by Mendenhall in 1876 and Hastings in 1878 Both these physicists confirm the statement of Arago and Neumann that for glass the law is precisely the reverse of that given for liquids, and that the refractive index increases with the temperature. Mendenhall calls attention to the effect of this change upon the determination of the position of spectrum lines, especially with a train of prisms, and suggests that it may account for the discrepancies observed in the values given by different observers for the same line. In the case of the Thollon prism described in this paper, it will be observed that the deviation, and consequently the refractive index, increases in a very marked manner as the temperature diminishes; confirming Gladstone and Dale's law for carbon bisulphide. When the prism was cooled from 22° C. to 9·6°, the double sodium line moved toward the violet end of the spectrum over a distance of 3·583in.[*] As Mendenhall has shown that no change takes place in the angle of a glass prism with change of temperature, it follows that the flint-glass prisms composing the sides of the Thollon prism change only in their specific refraction with change of temperature. Hence the change of the refractive index observed in this prism as above stated is a differential result due to the excess of the change in the index of the bisulphide in one direction over that of the flint glass in the other.

Moreover it has now been most clearly shown that by means of a suitable thermostatic arrangement it is quiet possible to preserve the temperature of the prism so uniform that no material change of position shall take place in the spectrum lines, at least during any reasonable exposure. The numerical results above given prove that in the apparatus as arranged by Dr. Draper the temperature did not vary 0·1° C. for more than seven hours, and that during that time the sodium lines did not change their position by an amount equal to the distance between them. Hence this source of difficulty, hitherto so serious in spectrum photography, especially when the exposure is a long one, is entirely obviated.

These experiments, moreover, confirm the opinion that the irregularities in the bisulphide, which are the cause of its bad definition, are produced by an inequality between the temperature of the liquid and that of its inclosing vessel, thus producing convection currents in the liquid. So long as the temperatures of the prism and of its contents rise and fall together, and with the surrounding objects, so long the definition remains perfect, notwithstanding the temperature change. It is only when considerable changes of temperature take place suddenly that the striæ due to these convection currents appear and spoil the definition. As this is the condition in most working laboratories, the advantages there of a method of completely obviating the evil by agitation enables the experimenter to secure good definition with any changes of temperature. But now these changes of temperature, though they cannot produce bad definition, do cause shifting of the lines. The even temperature box already described cures this trouble completely. When this box has been at a constant temperature for a sufficient time, the definition is good even without the stirrer. Even when the temperature of the box is changing quite rapidly, good definition can be always secured by starting the stirrer.

It will ever be a source of profound regret to the many friends of Dr. Henry Draper that he did not live to complete the research to which the foregoing investigation was preliminary. With his new and admirably equipped laboratory, and with this powerful and thoroughly corrected photographic spectroscope at his command as one of its first fruits, no one can doubt that he would have secured with it results of the highest value to astronomical, and especially to solar, physics.

## ADJUSTABLE BEADING, RABBETING, AND SLITTING PLANE.

THE tool shown in the annexed engravings has been patented in the United States by Mr. Franks, and is one of merit, covering a large field of operations, and being very efficient in each, besides being light and handy and occupying much less room in the toolbox than would be required for the several tools whose place it fills. Fig. 1 is a side, and Fig. 2 a top view of the tool as a whole. Pieces A and B form the body of the plane, between which the bits and the tools are carried, except the slitting knife, which is carried by A above. In the figure, T is a beading tool shown in position, having a bearing or seating in both A and B, so as to support it on both sides, and being locked in position by the thread screw C. At G is a depth gauge, which is moved over into the hole at D, when that position is most suitable for the kind of work in hand. Piece B is made adjustable in its distance from A, so as to accommodate different widths of bits by sliding it on the arms M, securing it in its adjusted position by the set-screws S. Similarly, the fence F slides on arms M, and is secured in its adjusted position by the set-screws H, thus enabling it to regulate the distance from the edge of the board at which the bits shall operate, and also to guide the bits true to the edge of the board or work. F is provided with an upper and a lower power of holes, so that it may be set on the arms H at two different heights, as may best suit the nature of the work. W in Fig 1 is a spur for cutting the end grain of the wood in advance of the bit, as it is necessary on dado and other cross-grain work. The construction of the spur is seen more clearly in Fig. 3. The pieces A and B are provided with a recess, having four arms or branches, while the spur itself has but three, so that the spur may be set as in Fig. 1, and be out of action; its screw being loosened, it may be given a half-turn, so that one of its arms will come below B, as at X in Fig. 5. The cutting edges of the spurs come exactly flush with the outside faces of A and B, and the bits are so held in their seats that their edges also come exactly flush with their outside faces, which therefore act as guides to the bit. Fig. 4 shows a plough in position on the work, A and B being shown in section. It is seen that their inner edges being bevelled will, in using a beading tool, act as a gauge regulating the depth of the cut, which will equal the amount to which the cutting edge of the bit projects beyond the bevels of A and B. Similarly in grooving or ploughing, the amount to which the bit projects below the lowest points or edges of A and B regulates the thickness of the shaving, and as A and B follow the bit into the work, the blade being once set, the work may proceed without altering or touching the bit, which will operate until prevented by the depth-gauge meeting the surface of the work. This principle of the side pieces A and B entering the work with the bit and being adjustable in width apart to suit various widths of bits, gives to the tool the capacity to serve for a very wide range of work. It will be seen that this tool, which is made by the Stanley Rule and Level Company, of New York, is capable of doing a great variety of work, and it is supplied with nine bits, nine beading tools, and a tonguing bit, provided with an adjustable depth gauge.

## PROF. LANGLEY ON THE SOLAR RAYS AND THE ATMOSPHERE.

AT the Royal Institution Prof. Langley, of the Allegheny Observatory, Pennsylvania, recently delivered his promised lecture on "Sunlight, and its Absorption by the Earth's Atmosphere," in the course of which he said that Plato once asked what would be the feelings of a man who had lived in a cavern all his life when he was brought for the first time out into the glorious sunlight? Are not the dwellers upon earth somewhat in the same condition? The supposed transparency of the atmosphere above us is deceptive in many ways;

---

[*] In the earlier series of experiments the change in position of the Na lines was very closely 0·1in. for one degree Fahrenheit. In the later series it was almost exactly 0·8in. for one degree Centigrade. The results of the two series cannot be compared together owing to a change in the adjustment of the apparatus during the interval.

we have never seen the sun as it really is, and there is reason to suppose that the true colour of the sun is blue, or bluish white. Our atmosphere forms a kind of coloured ceiling, so we do not see the normal colour of the sun; if we lived always under a transparent roof of a red colour, should we not believe the colour of the sun to be red, because we had never had an opportunity of getting outside the roof? Might not some of those fishes with large eyes, dredged up from great depths, have been of opinion that the sun has a greenish hue? His own researches tended to prove that our atmosphere has an orange tinge, and that the rays of the sun, with their large proportion of blue, reach the surface of the earth of the colour we call white.

is the experience of every one, in all parts of the world, that when the sun is low on the horizon his rays are more orange than at other times, and this is due to the large volume of the earth's atmosphere through which they then pass before reaching the eye. Prof. Tyndall discovered that the blue colour of the sky is due to fine particles in the air, which exercise selective absorption of the rays of the solar light. Prof. Langley, by the aid of the electric light, threw a bluish white disc of light upon the screen; then he made known that he was using blue light, which appeared nearly white upon the screen, because he passed it through orange glass, representing the atmosphere of the earth. In analysing light, a glass prism squeezes the rays of the red end of the spectrum together; a Rowland's grating gives the effect of twenty or thirty prisms, without unduly compressing the red end of the spectrum; the one he held in his hand contained a hundred lines within the width of a single human hair. When measuring the influence of the invisible ultra-red rays, they had to work in the dark; he found that the thermopile was not sensitive enough for the purpose, so invented the bolometer, in which an infinitely fine wire of platinum, or iron, has its temperature changed in different parts of the spectrum; as its temperature changes, it varies in electrical conductivity, and the amount of such change is indicated on a very sensitive galvanometer. An iron wire, sometimes used in the bolometer, was made by him out of a leaf of iron so thin that 15,000 would occupy but 1in.; these leaves were made in a competition between English and American iron manufacturers. To get as high as he could above the bottom of the earth's atmosphere, he at first thought of the Peak of Teneriffe, but it was too cloudy there; the same objection applied to the Rocky Mountains; he wanted the driest place he could get. As he had a military escort to help him, one of the peaks of the Allegheny Mountains, in California, was chosen, where the mountains rise from a torrid, burning desert, peopled only with grey rattlesnakes with a most venomous bite—a desert dotted with the skeletons of animals and emigrants. The mountain selected rose 12,000ft. above the plain and 15,000ft. above sea level. The heat at the bottom was intense, tanning them like Indians, and the first forest trees began to grow only at a height of 6,000ft. above that level. It took four days to climb the mountain, and the mules, which carried the instruments, ascended by a longer route. Measurements of the heating power of different parts of the spectrum were taken at the top and bottom of this mountain, with the result that at the higher station he found the ultra-red end greatly elongated. He measured the heating power of rays far beyond the point where the radiation had been previously thought to cease, and beyond the point where Captain Abney had photographed them with so much precision. He had also discovered that some of the blue rays were ten to twenty times more intense at the top of the mountain than at the bottom. His expedition to Mount Whitney had discovered that without the protecting veil of aqueous vapour in the atmosphere mercury would freeze in the direct rays of the sun, also that the power of the solar radiation had been previously underestimated, likewise that the absorption of the atmosphere is nearly double that previously supposed. Some of these experiments were carried on at the expense of a citizen of Pittsburgh.

## SOLDERING AND REPAIRING PLATINUM VESSELS IN THE LABORATORY.*

It frequently happens in the laboratory that platinum vessels, after long-continued use, begin to show signs of wear, and become perforated with minute pinholes. When they have reached this stage they are usually accounted of no further utility, and are disposed of as scrap; not that it is impossible to repair them—for with fine gold wire and an oxyhydrogen jet this is easily feasible—but that the proper appliances and skill are not in possession of all. Irrespective of the manipulation of the hydrogen jet, it is rather difficult without long practice to hold the end of the fine wire precisely over the aperture and to keep it in position. It occurred to me that if the gold in a finely-divided condition could be placed in very intimate contact with the platinum, judging from the fusibility of gold-platinum alloys, union could be effected at a lower temperature over the ordinary gas blowpipe. I tried the experiment, and found the supposition correct. The substance I used was auric chloride, $AuCl_3$, which, as is well known, splits up on heating, first into aurous chloride, and at a higher temperature gives off all its chlorine and leaves metallic gold. Operating on a perforated platinum basin, in the first instance, I placed a few milligrammes of the aurous chloride from a 15-grain tube precisely over the perforation, and then gently heated to about 200° C. till the salt melted and ran through the holes. A little further heating caused the reduced gold to solidify on each side of the basin. The blowpipe was now brought to bear on the bottom of the dish, right over the particular spots it was wished to solder, and in a few moments, at a yellow-red heat (in daylight), the gold was seen to "run." On the vessel being immediately withdrawn a very neat soldering was evident. The operation was repeated several times, till in a few minutes the dish had been rendered quite tight and serviceable.

Using the gold salt in this way the principal difficulty experienced in holding gold wire unflinchingly in the exact position vanishes, while only a comparatively low temperature and small amount of gold is necessary. Care must be taken to withdraw the platinum from the flame just at the moment the gold is seen to run, for if the heat be continued longer the gold alloys with a larger surface of platinum spreads, and leaves the aperture empty. As in the case of all gold-soldered vessels, the article cannot afterwards be safely exposed to a temperature higher than that at which the soldering was effected, and on this account it is advisable to use as small an amount of auric chloride as possible. When the perforations are of comparatively large size the repairing is not so easy, owing to the auric chloride, on fusing, refusing to fill them. I find, however, that if some spongy platinum be mixed with a few milligrammes of the gold salt, pressed into the perforation, and heat applied as directed, a very good soldering can be effected. It is well to hammer the surface of the platinum while hot, so as to secure perfect union and welding of the two surfaces. This may be done in a few minutes in such a manner as to render the repair indistinguishable. Strips of platinum may be joined together in much the same way as already described. A few crystals of auric chloride placed on each clean surface and gently heated till nearly black, then bound together, and further heated for a few moments in the blowpipe flame. Rings and tubes can also be formed on a mandrel, and soldered in the same fashion, and the chemist thus enabled to build up small pieces of apparatus from sheet platinum in the laboratory.

## BIRKMANN'S LATHE AND DRILL PRESS CHUCK.

This chuck, the invention of George Birkmann, 258, West 29th street, New York City, is represented in the accompanying detail engravings. It consists of a conical sleeve adapted to be screwed It the spindle, or to be otherwise attached to either the loose or fast spindle. This sleeve is connected by means of a screw collar with a cylindrical socket adapted to receive smaller sockets or bushings for holding pieces of different sizes. Fig. 1 is a section of chuck with detachable sockets in place, Fig 1*a*, a side view of the smallest tool socket; Fig. 2 is a section of the chuck arranged to hold a shaft; Fig. 3 represents the chuck attached to the tail stock spindle of a lathe, and Fig. 4 is an end elevation and part section of chuck. In these engravings A represents the conical sleeve that screws to the spindle S, shown in Figs. 1 and 2; C is the threaded collar that holds the main socket D in place. The main socket receives one or more smaller sockets, $D_1$, $D^2$, $D^3$, as clearly shown. When the chuck is to be used for shafts, cylinders, sockets E, Fig. 2 are used, which are secured by set screws; collar $E^1$ prevents longitudinal motion. Fig. 3, representing the chuck on the tool spindle, requires no explanation. This chuck, we (*American Machinist*) are informed by Mr. Birkmann, is in use by himself and others for various kinds of work for which it is suited with satisfactory results.

**Mercuric Chloride as a Disinfectant.**—Dr. George M. Sternberg, in his recent reports to the American Public Health Association, confirms the opinion arrived at of late years in more than one quarter as to the very powerful antiseptic action of perchloride of mercury. He relates experiments in proof of the inhibiting action of very dilute solutions upon the development of the bacilli of anthrax and other micro-organisms, and sums up his conclusions thus:—"Mercuric chloride, in aqueous solution, in the proportion of 1 in 10,000, is a reliable agent for the destruction of micrococci and bacilli in active growth not containing spores; and in the proportion of 1 in 1,000 it destroys the spores of bacilli, provided that the micro-organisms to be destroyed are fairly exposed to its action for a sufficient length of time. A standard solution of 1 in 1,000 may be safely recommended for the disinfection of bedding and clothing which can be washed, for washing the floors and walls of infected apartments, for disinfecting the hands and instruments of surgeons and gynæcologists, and as a disinfecting wash for superficial wounds or mucous surfaces. For continuous application to wounds, &c., a solution of 1 in 10,000, or less, should be effective. A standard solution of 1 in 500, with the same quantity of potassium permanganate, may be safely recommended for the disinfection of liquid fæcal discharges, and other fluid material supposed to contained 'disease germs,' provided the time of exposure is not less than two hours, and the quantity of material to be disinfected is not in excess of that of the standard solution used."

In Prussia all express trains are to be provided with means of communication before the close of the current year, and all other passenger trains within a year more. The Prussian railways simply use a cord, running outside and just above the level of the window. This cord is to be connected with the locomotive whistle for giving the signal.

# SCIENTIFIC NEWS.

THE death is announced, at the untimely age of 28, of Mr. Alan Bagot, the author of several well-known works on colliery ventilation, mining accidents, and lately of the "Principles of Civil Engineering as applied to Agriculture and Estate Management." He was also the inventor of apparatus for saving life and preventing accidents in mines.

The death is also announced of Mr. J. D'Aguilar Samuda, the famous shipbuilder of Millwall.

The results of a large number of observations of comets and small planets made during 1884 at the Vienna Observatory are given in Nos. 2658-9 of the *Astronomische Nachrichten*, which also contain a series of observations of Hyperion made at Washington in 1881-1885 by Prof. Asaph Hall.

It has been pointed out that at the time of totality in the solar eclipse of Sept. 9 next, Jupiter will be within the coronal limits. At the middle of the eclipse, as observed from Castle Point, south-east coast of the North Island, New Zealand, the distance of Jupiter from the moon's limb will be 46′. Saturn was within the coronal limits during the eclipse of Dec., 1870, but does not appear to have been observed.

The two small planets, Nos. 245 and 247, discovered respectively by Mr. Pogson, of Madras, on Feb. 6, and by Dr. Luther, of Düsseldorf, on March 14, have been named Vera and Eukrate.

The arrangements for the meeting of the British Association at Aberdeen in September next are being completed, in accordance with the suggestions of Prof. Bonney. Upwards of £2,000 has been promised to the guarantee fund. The Artists' Society will hold its exhibition during the meeting instead of in the summer, and it will be free to members of the Association; natural history and archæological exhibitions have also been suggested.

The next meeting of the American Association will be held at Ann Arbor, Michigan, commencing August 26.

The Hon. Donald A. Smith has since September last given to McGill College, Montreal, the sum of £24,000 for the establishment of separate lectures for women preparing for the B.A. or equivalent degree.

Mr. R. Meldola has been appointed Professor of Chemistry in the Finsbury Technical College.

Mr. Shelford Bidwell, M.A., read a paper before the Royal Society last week "On the Changes Produced by Magnetisation in the Length of Rods of Iron, Steel, and Nickel." He finds that the length of an iron rod is increased by magnetism up to a certain critical value of the magnetising force, and if that is passed the elongation is diminished in proportion as the magnetising force increases. The amount of the maximum elongation appears to vary inversely as the square root of the diameter of the rod. In soft steel magnetisation produces elongation; and with hard steel the critical value of the magnetising force becomes very high. In soft steel a temporary elongation once produced may be maintained by a magnetising force too small in itself to produce any elongation. Nickel continues to retract with magnetising forces far exceeding those which produce the maximum elongation of iron. The greatest observed retraction of nickel is more than three times the maximum observed elongation of iron, and the limit has not yet been reached.

Part VI. of the third volume of the *Journal* of the Liverpool Astronomical Society contains a variety of short papers on astronomical subjects, and an interesting report on the Planetary Section, with observations of Saturn by the members of the Section.

At the meeting of the San Francisco Microscopical Society on March 11, Dr. Mouser exhibited his Thoma microtome, the construction of which is based on the principle that a body sliding between two inclined planes and touching the latter at five points only, will slide evenly and exactly over such planes, even if they are not geometrically true. A knife attached to such a carrier will therefore always cut perfectly parallel sections, and well-hardened tissues have been cut as thin as ·002mm. Mr. Breckenfeld, the secretary, exhibited a graduated "blue-glass modifier," which consists of a glass disc revolving upon an adapter under the stage of the microscope. It is "flashed" from clear glass to dark blue, and one-half of its surface being lightly ground, any desired tint of field may be obtained, from white to deep blue, either transparent or translucent, by merely revolving the disc.

At the meeting held on March 25 Mr. Berteling gave a demonstration of the capabilities of a new ophthalmoscope. A small circular film of thin glass is adjusted in the main axis of the instrument at such an angle, that, while it does not obstruct the rays of light illuminating the interior of the eye under examination, it reflects the image of the brightly illuminated "optic disc," which image is then amplified by a suitable lens system. In this way, a most thorough examination of the interior of the eye can be made with perfect comfort to the patient and without manipulative difficulty to the operator.

Dr. C. P. Bates exhibited a "warm stage," for use in the study of bacteria and similar organisms. The cell is laid upon a wooden slide resting on the stage, which slide has a central perforation for admitting the rays necessary for illumination, and is heated by two twisted copper wires, which form a loop directly under the culture cell, and then, passing out of the slide at either end, meet directly in front of it, and are there again joined and prolonged a distance of several inches. The free end is made to pass through the perforated chimney of a small lamp, and by adjusting the flame of this along the wire, the temperature of the culture cell may be raised or lowered until the desired point is reached. A delicate thermometer, adjustable on the slide, registers the temperature with great exactness. By the peculiar arrangement of the wires, the *entire slide* is heated with absolute uniformity.

M. J. Héricourt has presented a paper to the Paris Academy of Sciences, in which he states that in all waters, whatever their origin, there exist curved bacilli of variable forms and dimensions, among which those of the type described as choleriform are constantly found. The curved bacilli do not exist in the atmosphere under their characteristic form; they are there, however, in the state of germs. All substances capable of serving as nutriment to germs or bacteria contain curved bacilli.

M. Scheurer-Kastner read a paper before the Paris Academy of Sciences in which he stated that the heat of combustion of coal is much higher than has hitherto been supposed.

Water-gas as an illuminant has been condemned by the Massachusetts Board of Health on account of the large quantity (30 per cent.) of carbonic oxide it contains. Water-gas is odourless; and carbonic oxide being a deadly poison, it is considered risky to permit the general use of the gas. Coal-gas contains about 7 per cent. of carbonic oxide, but its odour is a sufficient safeguard. Water-gas can, however, be used with safety by impregnating it with some powerful odour; and by using it to heat incandescent caps of magnesia wire, it produces a brilliant and economical light.

The *Alaska* has been fitted with a new rudder in the United States. Its total weight is 15 tons, and it is stated that it is the largest piece of work of the kind ever made in America.

**The Franklin Institute's "Novelty" Exhibition.—The Franklin Institute purposes next Fall to open another exhibition in its building at Thirty-Second-street and Lancaster-avenue, where the late highly successful Electrical Exhibition was held, and a general circular has been issued giving information to the public. The new exhibition will be known as the "Novelties Exhibition," and will open on Sept 15 and will close on Oct. 31. Its exhibits will be restricted to such recent discoveries and inventions in the sciences, arts, and manufactures as are worthy, by reason of merit, to be admitted. Application for space can be made at once, and in announcing their plans the institute managers say that, while they will allow the widest latitude in the character of the objects admitted, the aim and intention will be to confine the same to such as shall possess, first, the qualification of "novelty," and second, the qualification of "merit," which shall redeem them from triviality. Awards of medals and certificates of merit will be made.**

# LETTERS TO THE EDITOR.

*[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]*

*All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

*All Cheques and Post-office Orders to be made payable to* J. PASSMORE EDWARDS.

⁂ *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

> **"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks a vice from whence great inconveniences derive their original."**
> —*Montaigne's Essays.*

## ζ HERCULIS.

[24165.]—WILL "A Fellow of the Royal Astronomical Society," or Mr. Sadler, be so kind as to examine the above star, and state the present distance of its components?

The latest date of measurement of this rapid binary given in Webb's 2nd edition is 1880, where it is stated as 1·4″, which would appear to be a maximum; but on looking at it last night (an exceptionally fine one certainly) with my 4in. Wray I was much surprised to see it distinctly double. I suppose that, theoretically, a 4in. should almost divide 1·1″, but I fear theoretically only, and although my telescope is an excellent one, I cannot doubt that the star has widened since 1880. **Beta.**

## HYPERION—DOUBLE STARS—TESTS FOR A 6½in. REFLECTOR.

[24166.]—I DID not *decide* that Mr. Holmes (letter 24100, p. 146) did not see Hyperion on March 14th. I merely said that I did not think it *probable* he saw so faint an object so long after the opposition of Saturn. Hyperion was not measured at Washington on the 14th of last month. On the 10th and 17th it was called "faint," and on the 20th "very faint," with the 26in. refractor. I know of no evidence tending to show variability in either Hyperion or Titan. Prof. Hall remarks that the number of faint stars near Saturn's path in 1885 rendered the identification of Hyperion rather difficult. Mr. Holmes will, I think, find, on looking again at the "E. M." for February 1883, that the letters referred to by myself are on the close *comes* of $\theta$ Aurigæ; in fact the discussion was started by a letter from Prebendary Webb on the smallness of the *comes*. This *comes* is, as I have said, probably variable; for we have the evidence of the first of all double-star observers as to its magnitude in 1875, 1876, and 1877. De. would certainly not have given the colour of a star so small as 10·0 Σ. on four different occasions; and he writes of the two stars, and the seeing at the time, as follows:—

1875·693 3·0 *bianco verde chiaro*: 7·0 *azzurro cinereo*: bene.
1876·074 3·0 *bianca*: 8·0 *azzurro chiaro*: ottima.
1876·786 3·0 *gialla chiaro*: 7·5 *azzurra*: colori certi: sufficiente.
1877·263 3·0 *verde chiaro*: 8·0: *cinerea*: discreta.

All the measures were made with a power of 500 on the 7½in. refractor, and the last measure by daylight. Mr. Tarrant, who has examined this object on several occasions during the last fortnight with three reflectors, by With and Calver, of 8½in., 10½in., and 12½in. apertures, writes to me that he should rate it at about 8½ mag., but that it looks smaller from its colour—to him very blue.

$\alpha^2$ Cancri *is* mentioned by Webb in the 4th edition of "Celestial Objects," and Mr. Holmes will find notes on it as a double star in the ENGLISH MECHANIC for April 1 and June 24, 1881. It is called $\alpha^2$ because if there chance to be two or more stars close together, and all are called $\alpha$, the preceding one of all is called $\alpha^1$, the second $\alpha^2$, and so on, e.g., $\alpha^1$ $\alpha^2$ Capricorni, $\beta^1$ $\beta^2$ Capricorni, &c. The place of $\alpha^2$ Cancri for 1880 is 8h. 51m. 54s. + 12° 19′, and it is about 4½ mag. $\alpha^1$ Cancri is a small 6 mag. star about 2½ minutes of time preceding, and 15′ south of $\alpha^2$. $\alpha^1$ is not catalogued as a double star, but $\alpha^2$ is H 110, having a faint companion at 325° : 11½″; $\alpha^2$ is the star shown by Proctor.

I am obliged to Mr. Hirst (letter 24101) for his communication. I should be glad if he would look up $\gamma$ Lupi and $h$ 5114 Telescopii. The latter is Lac. 8091, and its place for 1885·0 is XIXh. 18m. 34s. − 54° 33·2′. There is something very mysterious about both these pairs; unfortunately the double star measures of the Sydney Observatory are so unreliable and so carelessly made, that little can be made out from the recent observations of these two objects there.

"Aleph" (letter 24102, page 146) will find many tests for a 6½in. reflector in the last twenty volumes of the ENGLISH MECHANIC; but, in case he has only recently become a subscriber, I append a list of some naked-eye pairs visible at this season. I have given the distances without the angles, that he may not be biassed. The magnitudes are in Struve's scale, and the stars are arranged in order of difficulty, so that, while he should see χ Turdi Solitarii, γ Crateris, and 44 Virginis easily with that aperture, he will probably find ζ Böotis or 46 Virginis too severe for him until he has had considerable practice with his instrument.

DIVIDING TESTS (1).

| | A. B. C. | |
|---|---|---|
| χ Turdi Sol. | 6·0, 7·3, 8·2 | : 35·0″; 1·39″ (B—C). |
| O.Σ. 235. | 6·0, 7·7 | : 1·30. |
| ξ Scorpii. | 4·9, 5·2, 7·2 | : 1·31 (A—B); 7·3. |
| 14 Lyncis. | 6 0, 7·1 | : 1·0. |
| ν Scorpii. | 4 0, 6·5 (A—B); | : 0·81; 40·8 (A—C). |
| | 7·0, 8·0 (C—D); | : 2·07. |
| μ² Boötis. | 4·5, 6·5, 7·8 | : 108·4; 0·75 (B—C). |
| 25 Can. Ven. | 5·7, 7·6 | : 0·70. |
| ζ Boötis. | 3·5, 3·9 | : 0·66. |

DEFINING TESTS (2).

| | | |
|---|---|---|
| γ Crateris. | 4 0, 10·0 | : 5·14″. |
| η Draconis. | 3·0, 9·5 | : 4·88. |
| 90 Herculis. | 5·8, 9·2 | : 1·83. |
| 11 Scorpii. | 6 0, 10·3 | : 3·35. |
| κ Leonis. | 5·0, 10·5 | : 3 05. |
| 6 Serpentis. | 4 6, 9·4 | : 2·28. |
| 46 Virginis. | 5·7, 9·0 | : 1·25. |

SPACE-PENETRATING TESTS (3).

| | | |
|---|---|---|
| 44 Virginis. | 6·0, 11·2 | : 21″0. |
| γ Libræ. | 4·5, 11·7 | : 41·3. |
| ρ Boötis. | 3·6, 11·7 | : 53 3. |
| 85 Virginis. | 6·0, 11·8 | : 43·3. |
| 53 Virginis | 5·5, 12·3 | : 70 9. |
| 72 Virginis. | 6 0, 12 0 | : 29·2. |
| B.A.C. 3607. | 5·7, 12·2 | : 24·6. |

The place of χ Turdi Solitarii for 1880 is XIVh. 18m. 47s. − 19° 26′; of O. Σ. 235 XIh. 25m. 31s. + 61° 45′; of B.A.C. 3607, Xh. 26m. 14s. + 41°·12′. "Aleph." will find all the others shown on any decent map. It is remarkable that all the faint companions in list 2 are of a markedly blue hue, as also are the companions of ξ and ν Scorpii, 14 Lyncis, and 25 Canum. A of 44 Virginis is a very close pair, the distance not exceeding 0·35″.

April 22nd. **H. Sadler.**

P.S.—The distance of ξ Ursæ Majoris is now about 1 8″, and it is therefore more of a test for a 2½in. than a 6½in. telescope. I saw it well divided with the 3·2in. Sheepshanks equatoreal, power 230, a few nights ago.

## DARK TRANSIT OF JUPITER'S FOURTH SATELLITE.

[24167.]—THIS was well seen at Shaftesbury on April 18th. At 20h. 15m. the fourth satellite appeared as dark as the shadow of the third just then approaching the limb. The air was unsteady, but at moments of good definition the outline of IV. was sharp and circular. It was watched until egress, and was only lost sight of for two minutes, after which it was seen passing off the planet, being then of a very dull slate colour. For an hour after egress it appeared very faint. Observation then ended. Instrument 8½ Calver reflector.

April 24th. **T. Perkins, M.A.**

## TRANSIT OF JUPITER'S III. SATELLITE.

[24168.]—AT 7 p.m. on the 25th I turned my telescope on Jupiter, and found the III. Satellite just visible as a dark dot 54 minutes from egress. I was called away, and returned to find it just within the limb; it then appeared a shade brighter than the planet. I watched it to egress; but detected no diminution in brightness, as recorded by Mr. Tweedale with respect to Satellite IV. after egression on 18th inst. **T. R. Clapham.**

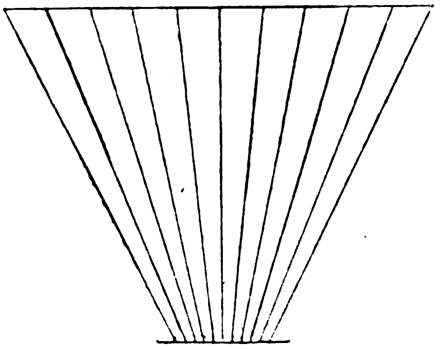
## SOLAR ECLIPSES AND OCCULTATIONS BY THE MOON.

[24169.]—THE accompanying communication was "rejected" by the Council of the Royal Astronomical Society, "after careful consideration," from appearing in their *Monthly Notices* on the plea that a similar communication had been published in the ENGLISH MECHANIC, and that it was against their "rule" (query, Which rule? and where expressed?) to allow it to appear under these circumstances. It is desirable that your readers should be aware how disinterestedly the progress of science is regarded by the Council; and as many amateurs are availing themselves of the new method of computation, I hope you will think it worth while to republish it at length.

That it is possible to make short work of the computation of the circumstances attending solar eclipses and occultations by the moon, is a discovery which cannot but be welcomed both by professional and amateur astronomers. Those circumstances differ much in different places, even though not very remote from each other: and therefore, unless a calculation be made for each place separately, it is impossible to predict the time and the angles connected with these phenomena with anything like the accuracy requisite for a valuable observation of their occurrence. The method of Woolhouse, as given in the appendix to the *Nautical Almanac* of 1836, occupies 98 pages, the figures alone including 7 pages. The method of Shadwell (an abbreviation of the former) fills a volume of 136 pages, and the figures of each eclipse take up 2¼ of those pages. The method devised by Penrose—which suggested the method to which I desire now to call your attention—is almost entirely graphic; but drawn on so small a scale that its accuracy can scarcely be relied upon to less than four minutes of time.

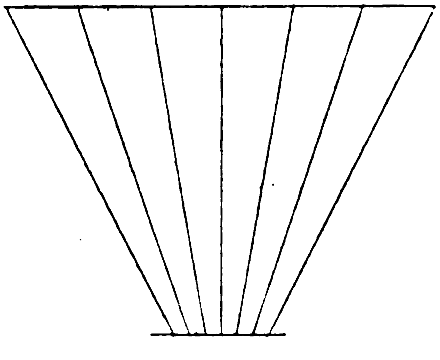
It is now proposed to introduce a method which is partly graphic and partly computational, by means of which correct results can be obtained to within half a minute, and which can be worked out to three-quarters of an hour.

FIG. 1.



In all previous methods of working out eclipses and occultations by a graphic process, as given in the various treatises on astronomy, the principle of the computation has been to represent on the projection of a single spheroid any requisite number of similar ellipses, diminishing in magnitude as they recede from the equator; whereas in my newly-devised method the principle is, as suggested by Penrose, to construct a single ellipse, and then to have that ellipse referred to different and receding equators.

FIG. 2.



The construction of an ellipse, when strict accuracy is insisted upon, is, however, a tedious and somewhat difficult process, and where that process has to be repeated for every separate case of eclipse or occultation, it is no wonder that computers shrink from the attempt, notwithstanding that the results of the calculation are so desirable and valuable. The first advantage of the new method consists in this: That a system of ellipses has to be delineated once for all, and in order to insure a due degree of accuracy, the common semi-major axis of these ellipses is 10in. long. They are concentric, and have their semi-minor axes of various lengths, 10 sin. 5°, 10 sin. 10°, 10 sin. 15°, &c., up to 10 sin. 25°. The ordinates drawn to these ellipses have for their abscissæ 10 sin. 15°, 10 sin. 30°, 10 sin. 45°, &c., corresponding to the hours I., II., III., &c., and these may again be easily divided into intervals of 10 minutes each. The system of ellipses thus drawn is treasured up for constant use.

The scale upon which the diagram has to be drawn must next be calculated. Ten divisions of it are exactly equal in inches to the numerical value of the quantity $\frac{100}{P\,\rho\,\cos.\,l}$, where P is the moon's horizontal parallax, ρ the earth's radius, and *l* the *geocentric* latitude of the place of observation. This scale is thence called the latitude parallax scale.

It is only necessary further to say that the moon's relative horary motions in Right Ascension and Declination are taken from the *Nautical Almanac* by the usual methods, and by this means is plotted to scale the moon's relative orbit, which orbit must be subdivided into hours and minutes. Allowance can also be made for its *curvature* in particular cases.

A few additional remarks will help us to complete the computation.

Having calculated the sun's hour angle at the instant of Greenwich Time of true conjunction, let two lines be drawn at right angles to each other, and let them be so placed that when the ellipse is copied from the before-mentioned system of ellipses, *which corresponds to the sun's declination*, the place of the sun, as shown by the hour-angle on the ellipse may be found in *the centre of the paper*, so as to give room for the whole diagram, and the ellipse must be *above* or *below* the major axis according as the declination is *south* or *north*.

The moon's relative orbit is drawn by means of two co-ordinates, one corresponding to the Relative Horary Motion in Right Ascension, and the other to the Relative Horary Motion in Declination. And the distance of the former co-ordinate axis from the major axis of the ellipse first drawn (and to which it is parallel) is equal to the quantity,

$$\text{Diff.} - \text{dec.} \backsim P\rho\,\sin.\,l\,\cos.\,\delta$$

being *above* or *below* it, according as this quantity is *positive* or *negative*. The algebraical sign of the moon's Relative Horary Motion in declination indicates whether the moon's motion is *ascending* or *descending*. Thus drawn, the moon's Relative Orbit is subdivided into hours and minutes ranging along its whole length, the point where it intersects the vertical line being made to indicate the sun's hour angle at conjunction.

Lastly, from the latitude-parallax scale there is taken an extent equal to the sum of the semidiameters of the sun and moon, and the extremities of this line are so arranged as to indicate the same hour and minute in both the ellipse first drawn and the moon's relative orbit. This gives at once the local times (apparent) of beginning and ending, from which the local mean time or the Greenwich mean times may be found at once.

The magnitude of the eclipse is found by subtracting from the sum of the semidiameters the least distance of the centres of the moon and sun, and dividing the difference by the sun's diameter.

To find the duration of totality in a total eclipse, or the interval between the formation and rupture of the ring in an annular eclipse, subtract the diameters of the moon and sun, or *vice versâ*. Then measure off this difference on the latitude-parallax scale, and apply the said difference to the moon's horary scale. The interval sought will thus be exhibited in minutes.

To find the direction of the zenith or vertex, draw lines from the centre of the earth (which is indicated by the diff. − dec.) to the places respectively of beginning and ending, and measure the angle between these and the lines which join the contemporaneous times of beginning and ending on the ellipse and on the moon's relative orbit.

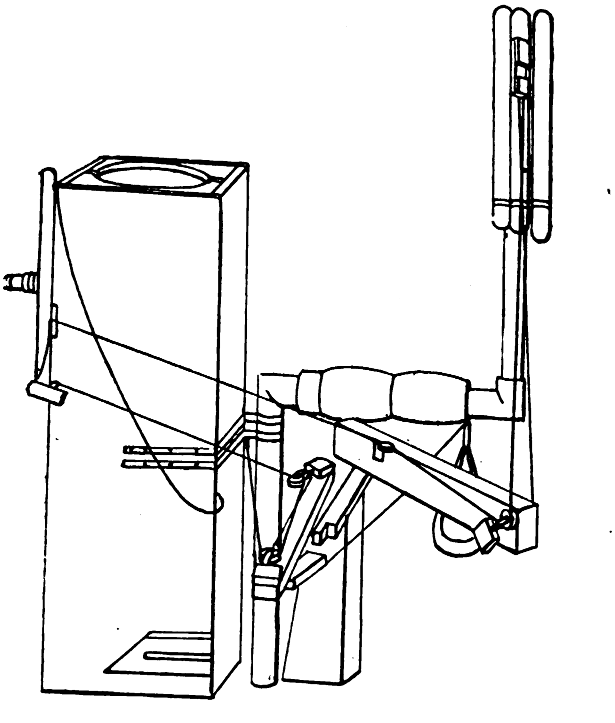
**James Pearson, M.A., F.R.A.S.,**
Late Scholar of Trinity College, Cambridge.

POSTSCRIPT.—The subdivisions (1) of the latitude-parallax scale, and (2) of the moon's horary scale, may be much facilitated by employing two separate diagrams constructed as follows:—

1. Let two parallel lines be drawn 5in. or 6in. apart from each other with a line at right angles to each for a central line, and let the scale be extended to five divisions on each side of each line.
2. Let another diagram be constructed similar to the former, but with six divisions instead of 10.
3. To take out the moon's Hor. Mot. in R.A. from the *Nautical Almanac*, call the seconds of time as minutes of arc, and increase them by half as much again. Then multiply the result by the cosine of the moon's Dec.
4. To take out the moon's Hor. Mot. in Dec., call the seconds of arc as minutes of arc, and divide by 10.

## A CHEAP AND EASILY-CONSTRUCTED TELESCOPE STAND.

[24170.]—As "Montmartre," on page 451, Vol. XL., stated that he feared to mount his telescope on the stand I described on page 407, Vol. XL, and recommended to him, from its weight being 100lb., and also from the satisfaction I experienced in the use of the 6½in. reflector as there described, I resolved to dismount my 12in. Calver, weighing 150lb.,



from its common altazimuth stand, and mount it like the 6½in. Of this I now inclose a photograph, and I can strongly recommend it to anyone requiring a useful, handy, and steady stand—as also a cheap one—and easily put together by anyone. I have used larger tubing than on the other stand, it consisting of 2½in. turning in 3in. tube, and I also have made the arms turning with the spindle of unequal lengths, so as to keep the telescope as near the post as possible, and the longer arm carrying a weight to counterpoise the telescope when vertical. I have not been able to place the eyepiece opposite the centre of motion, owing to the narrow house I have got to put it in, so that it is not the best form of stand; but it is so handy and smooth in its motions, and also so steady, that I am quite satisfied with it, and intend to mount my 15in. in a similar manner. I have photographed it in a vertical position as best for showing the levers and strings for directing it and regulating its motions, as also its attachment to the tube. The weights for balancing it in altitude are sash weights, and being hung on a piece of wood placed inside the upright tube any required tension can be given to the string which raises or lowers the direction of the telescope by keeping the weights farther from or nearer to the tube by a cross pin through the wood.

The strings cross the telescope so near the centre of motion as not to be interfered with by the telescope in any position. The photo will show that the spindle, 2½in., carrying the horizontal arms, 3in., turns in a socket piece of 3in. tube, which is fixed to a post in the ground. Through the horizontal arms is a 2½in. tube, having elbow pieces at each end, into which are screwed two lengths of 2½in. tube, one pointed up and the other down. One of these carries the telescope and the other weights—so heavy as just to allow the telescope to point upwards when uncontrolled. On the spindle, and close to the arms, is fixed a wooden lever 4 by 2in., and 3ft. long, on which are fixed two pulleys, one near the spindle and the other on the end and side of the lever. Through these pulleys a string runs from a gimlet in the bottom and side of the telescope, near the eyepiece, through another pulley fixed on the end of the upright tube, and thence returning to the end of the lever again. This string governs the telescope in altitude. This lever is not fixed at a right angle to the arms; but so as for its end carrying the pulley to be under the tube carrying the weights.

A second and double lever, or a fast-and-loose one, is put on to the socket piece in which the spindle turns. It is made of two pieces of 2in. square wood, one 3 and the other 2ft. long, having a joint at one end and a hollow to embrace the socket and a thumb screw at the other end of the shorter piece to screw into the longer, and bite the socket like nut-crackers. On this lever are fixed four pulleys, the first near the post and under the bottom of the lever, and the second at the end and on the same side of the lever. A string runs through these two pulleys from the end of the arm, through the second pulley, and thence through the first, and to a weight hanging close to the post, which will pull the telescope after a star. To control this motion a second string runs through two pulleys on the other side of the lever, one on the end and the other near the post, from a second gimlet in the bottom and side of the telescope, just below the other, to the other end of the arm. This string will allow the telescope to move after the star just as fast as the gimlet is turned; and with these two motions a star may be kept in the field as long as required, and the motion is smooth and steady. This fast-and-loose lever is usually placed at right angles to the arms, and the telescope will turn about 45° before it requires to be moved, and it is very seldom the telescope is kept for so long a time on one object. The thumbscrew may be screwed just so tight as to allow of the lever being moved by a hand placed on its end and a second hand on the other lever, and thus the telescope may be turned in any direction without unscrewing the thumb-screw, and yet the lever will be stiff enough to govern the direction of the telescope.

A disc of wood about a foot diameter fixed in the top of the post, and through this the socket protrudes, and on it the levers lie if left loose. Such is the stand I have now used for three months, and can strongly recommend for either reflector or refractor. **Philip Vallance.**

## THE DOUBLE TELESCOPE.

[24171.]—I have to thank "F.R.A.S." for reply 23918, 13th March, giving his opinion concerning result of dividing an 8in. object-glass down the centre and mounting the two halves binocularly (after the suggestion of "W. T. N.," 23850, of 20th Feb.), compared with result of two whole 3¾ o.g.s reduced by ⅝ segment only. He assumes that two halves will give the same aggregate light as one whole undivided area; but he inclines to doubt the definition of the larger halves equalling that of the smaller whole lenses. It is evident that when a half-lens is asked to do the work of a whole one, which, in this case, it is asked to do in all points except in quantity of light (which, of course, is at least halved), the result must necessarily suffer somewhere in comparison.

Against this detraction, however, has to be placed the gain derived by bringing the two eyes instead of one into the consideration, and it is upon the inclusive calculation that I should wish all the opinions I can elicit before proposing to have the 8in. o.g. divided.

The alternative suggestion of Thompson (23921), March 13, to shunt the focal images of two parallel telescopes (of whatever width apart) into the requisite exact eye width of a single observer, by means of prisms or flats, as there sketched by him, for binocular use, is quite feasible, and I am disposed to think it was the plan adopted in the 7ft. double reflecting telescope, made by one of the Herschels, to which I alluded in my first letter (23670), Dec. 26, 1884. Personally, I have no belief in the successful application of prisms to the focal images of object-glasses, for I once thought I was going to solve the question by a binocular eyepiece, which would, by prisms, divide the focal image given by a telescope of any aperture into two pictures. It was duly made, and the maker even read a paper upon it before the R. A. S., but in practice it yielded disappointment only—great loss of light and poor definition.

Monsieur Joubert, the director of the Observatoire du Trocadero, at Paris, persists that it is right in theory and only faulty in construction; but after lending it to him for a year to perfect, it remains a non-success, though he still maintains his view.

These remarks would not apply to flats, which might be used with reflectors upon Thompson's plan, for while it would be exceedingly difficult to procure a perfect pair of 8in. lenses to work together binocularly, Mr. Calver would probably be able to turn out an exact pair of 10in. or 12in. mirrors for anyone disposed to mount them into a binocular reflector.

Here, however, is the great pull in "W. T. N.'s" proposition to divide a large object-glass—viz., that the perfect pair of semi-o.g.'s is insured *ipso facto*, ready made, by the operation.

Following up the letter of Mr. Phillip Vallance (23709), of 9th Jan., on the exceptional value for binocular use of his plan of mounting all telescopes with their eyepieces at a fixed uniform height by transferring the axis from the centre to the eyepiece and by means of counterweights, I found, on availing of his friendly invitation to revisit him in the country, that he now employs a second telescope to act as counterweight to the fellow one, so that he has several pairs of instruments now so mounted in counterbalance cradles always ready for work, of which an observer can make use in all directions without altering the level of his eyes or changing his seat, which revolves round the central pillar supporting the axis which carries the cradles.

This led me to feel that if this ingenious arrangement could be combined with an equatorial motion, we should reach perfection in this department.

It was recently remarked that if we went to the North Pole with our telescopes we might leave our equatorial stands at home, and I asked myself whether, instead of going to the North Pole, we could bring the North Pole to us for this purpose? Why should we not lay a floor in our observing chamber, on our own equatorial plane, in steps, fix our telescope pillar—à la Phillip Vallance—at right angles to such inclined (stepped) floor, and observe on a revolving seat with unequal legs cut to match the steps in the floor. **Montmartre.**

## CUTTING SCREW-THREADS.

[24172.]—At page 125 "Bow" (par 5) confuses indeterminate centring, which every screw-thread gives for itself, with that predicable centring which we need for interchangeable mandrels. What is not practicable is the making of a screw-nose which will serve as a centring agent for chucks which have been turned up on other screw-noses. The roughest screw-nose in the world will find a centre for itself, and will remain true for all chucks which, having been fitted to its thread and scraped up to its face, are subsequently turned up in their place. This is the system which interchangeable mandrels will supersede, just as interchangeable objectives for microscopes have superseded the old system, by which the buyer of a microscope-stand had in future to go back to that particular maker for all its appendages.

It is interesting to know that our old friend, "J. K. P." has made two pairs of lathes on which, two and two, chucks are transferable. Doubtless an expert workman like "J. K. P." could, with "a few judicious touches in a screwing lathe," make two mandrels side by side interchangeable. But that is not the universal interchangeability which the model standard mandrel-head is designed to achieve. Nor is it quite what was achieved by Mr. Evans, whose two mandrels, the first time that they were tested in the reversible chuck, ran so true that Mr. Evans said he had "never seen anything run so true in his life." Here there had been no judicious touching-up; the two mandrels ran absolutely true at once, and simply by the aid of the principles on which they had been constructed. If these results were attainable without the cylinder base and wide mandrel-face, how was it that Mr. Evans, who had spent much time in endeavouring to make chucks transferable without transfer chucks, never before accomplished it? How is it that, in accurate tool-making, the old screw fittings for shifting head-stock and for mandrel back-centre have both been superseded by cylinders?

I do not see why "a cutter made for a screw of any particular number of threads will not do for any other number." Perhaps "J. K. P." will kindly explain.

"Vulcan's" valuable letters are evidently the outcome of conscientious thinking, as well as ample practical knowledge. And he is so frank in setting himself right, that it is a pleasure to debate with him. In 24038, my second paragraph, line 15 should have read, "each transverse element radial to the cylinder." Perhaps we can develop somewhat further the points contained in this letter. What are the things we are talking about?

The object at which we are aiming is the formation of an angular thread derived from an isosceles triangle and truncated so that its altitude is equal to the length of its base. A triangle answering this purpose must be taller than that of 53° 8′, which is the isosceles triangle drawn in a square and occupying for its base one side of the square.

If we take an isosceles triangle of 50° we have 7½ per cent. of the length of its base for truncation and, in threads for scientific work, this gives a sufficiently blunt top for practical purposes. Of course, the thread would be roughed out by the ordinary chaser or point tool in the slide rest, and the only question is: By what method can an angular thread of 50° he best trued up and finished off, and, if necessary, in hard steel?

As a means for trueing up such threads with the utmost accuracy, I pointed out that the ordinary chaser cannot be used because no multiple-point tool can be made so as to cut an accurate thread. Then I showed that the angle of the thread cut by a V-point tool depends upon the accuracy with which its cutting plane is kept upon the line of centres: that the cutting velocity which can be given to such a tool when fixed in the slide-rest is inadequate for properly finishing the surface of the thread, or for completing its final portion. And I say that, by the use of a revolving V-cutter, or V grinding-wheel, traversed by means of change-wheel arrangements, and having its axis tilted for the pitch of the thread, the most perfect thread possible can be trued up with ease and certainty. In reply to Mr. Wenham's objections, I have shown, and so has Mr. Hines, that while the revolving lap-wheel or cutter would be inapplicable to a square-thread for want of proper clearance, it is perfectly applicable to a V-thread of 50° inasmuch as the revolving cutter or lap-wheel clears itself in cutting a spiral thread of this angle. Mr. Wenham persists in his assertion; but, after adopting the tactics of the fox in dodging about and running away from the issue, he gets cornered by Mr. Hines. He then takes to throwing the stink-pot, and declares that Mr. Hines' tools cannot be good because the noses of his mandrels are soft. It is obvious that we are always much indebted to practical workers like Mr. Hines when they leave their shop for an hour and sit down to tell us about their methods of doing difficult work, and it is necessary to reprobate offensive stratagems which would only prevent such men from contributing to our columns.

Mr. Wenham (page 126) says that the circular cutter, whether for V-threads or for square-threads, produces similar errors. He says: "It would be excessively difficult to adjust the inclined axis of the milling cutter in the line of centres," and so on. And he gives a simile of a cedar pencil marked with a spiral line, and a coin held with its edge to the spiral. Now, if anyone will draw two circles touching each other, say of the sizes of a shilling and a crown, and will then draw a straight line joining their centres, he will see that it is not possible to get the revolving cutter off the line of centres. Whether the axis of the revolving cutter is above or below that of the screw to be cut makes no difference whatever to the angle of the groove inasmuch as the cut finishes on the line of centres. Now, the inclination of the axis of the revolving cutter is given by a divided head upon the square which holds it in the slide-rest, and may be determined to a fraction of a degree, just as by means of the division plate on the mandrel-pulley any angular measurement can be set out on work between centres. The traverse of the cutter is, of course, determined by the change wheels under the guidance of the slide-rest, and there is, therefore, no difficulty whatever at any step of the process.

As to the shape of the groove left by the traverse of the revolving cutter, the best demonstration will be given by setting up on a small planing machine a slab of wood, plaster of Paris, or brass, and ploughing out the grooves which represent a screw-thread upon the flat. We take an oblong slab and plane across it parallel grooves, as if we were making a rack. If the slab is clamped down with its side parallel to these grooves, we get a strip of the surface of a screw whose radius is infinite, and the pitch of whose thread is zero. If the slab be fixed on a revolving plate, and we set its side at an angle, its grooves will represent developed threads of a corresponding pitch. By the shape of the cutting tool we determine the shape of the groove. The whole subject is now before us. If, instead of planing out the grooves of our rack by an ordinary ploughing tool we rig up a revolving cutter with its cutting plane normal to the movement of the planer-bed, the revolving fly cutter produces its counterpart groove as precisely as the planing tool. The only difference is that undercutting can be done with the planing tool, but not with the revolving cutter. In all these cases the fly cutter will cut a counterpart groove up to the limits of a full square, and, so far, will clear itself. At the end of the slab where the threads run out, we see their axial section. Any of these threads which do not undercut, can equally be produced upon the cylinder by the revolving cutter so long as they have no pitch, and are cut as annular grooves. In all these cases the axial section of the cylinder gives the same section of the threads as is given by the square end of the slab. If we take the cylinder and now add the element of axial traverse in the cutting tool, we put pitch into our thread, and it advances continuously as a spiral. The side of the square thread annulus lay in a plane of rotation. The side of the revolving fly-cutter also moved in a plane of rotation, and therefore could coalesce with it. But the side of the square thread spiral is *a rectangular helixoid* or spiral surface, and cannot be dealt with by a plane. In short, the spiral square-thread cannot be cut by a revolving fly cutter of this shape. Now the *rectangular helixoid* is described by a line *at right angles* to the axis, uniformly rotating around the axis, and, at the same time, advancing uniformly along the axis. But the side of the angular thread is *a skew. helixoid*, and is described by a line at *an acute angle* to the axis, but rotating and advancing uniformly in the same way. The question of clearance on the part of the revolving fly-cutter is in this case a mere question of degree. It depends upon the acuteness of the angle formed by the line which describes the helixoid, the radius of the cylinder on which the thread is cut, the radius of the fly-cutter, and the amount of the pitch which is given to the thread. An angular thread of 50°, making eight or ten turns per inch upon an inch mandrel-nose, is abundantly cleared by its counterpart revolving fly-cutter, and is cut just as perfectly as by a fixed point tool in the slide-rest, even if this be kept perfectly on the line of centres, but which, as I have said before, is a very difficult thing to be sure of.

It is now fully admitted that, with the revolving fly-cutter, the height of the cutter-axis makes no difference to the outline of the groove when on a cylinder, so long as the groove is annular and the cutter revolves in a plane which is normal to the axis of the cylinder. Here, then, the revolving cutter has the advantage, inasmuch as a fixed V-point tool, equally set for its cutting face to cut a groove normal to the axis of the cylinder, does depend for the outline of its cut upon the level of the cutter face. In order to show the extent to which the angle of the groove cut by the fixed V-point tool depends upon its level, the following will be an interesting experiment. In a 2in. cylinder of boxwood turn some large V-grooves, then stand the cylinder in a 2·5in. paper tube, and fill up the intervening space with melted wax or plaster of Paris. On planing down down the cylinder parallel to its axis, the juncture of the two substances will show the angle of the groove. At first there will be two points, then a double-funnel section whose connecting channel gets cut off as the stem of the cylinder intervenes, while the angular divergence of the sides gradually increases till the axial section is exposed. By planing down in various directions such grooved or screwed cylinders, we can develop the whole stereotomy of screw threads.

In "J. K. P.'s" valuable contribution (p. 149), it is stated that "when the cylinder is stationary and the revolving cutter is placed and moved horizontally, we also get a groove which is a counterpart of the cutter." This is true only in one case—*i.e.*, when an axial plane of the cylinder bisects the angular groove which is cut. If the cutter, when placed horizontally, does not revolve in an axial plane, we cut a groove, whose sides are not both of the same height, because the bisectrix of the angle is not normal to a tangent plane of the cylinder. In this case it is not the groove or projection-form of the cutter which has been changed, but only that the full measure of both sides of the groove is not shown by reason of the fact that the groove is cut obliquely upon the tangent plane. This deformation, by reason of defect in the surface upon which the cut is projected, must be carefully separated from substitution of cosine or secant for radius as the base of the triangle, when the tool is not kept with its face normal to the line of its cut. A third morphological factor is the helicoidal character of the screw-thread. This factor is the increasing inclination of the thread as it approaches the axis of the cylinder. Every screw-thread, if cut to the axis of the cylinder, would coincide with that axis, and thus become a straight line. Hence, at the axis of the cylinder the pitch of every screw-thread is infinite, just as the tangent of every angle at 90° is infinite. This is one of the things which makes the thread "a screw-thread"; and Mr. Wenham might just as reasonably say that the three-cornered outline of a triangular groove was due to the steel being badly tempered, as that this increasing pitch of the screw-thread is due to my V-point tool being used revolving instead of fixed.

We now have before us all the factors in the form of the counterpart groove — the outline of the cutting plane of the tool, the angle which this cutting plane bears to the line of the cut, and the competency of the surface upon which the cut is projected. I assume, of course, that the base of the cutting plane will always be so shaped as to give clearance, and that, in cross cutting, the sweep of the radius of the revolving cutter will be taken into account. Therefore, for the longitudinal fluting-groove to be received upon a competent cylindrical surface, the groove must be bisected by an axial plane—i.e., the centring of the cutter, whether revolving or fixed, is of primary importance. For the annular groove, and for the annular component of the helicoidal groove, the centring is of equal importance for the V-point cutter when fixed, but of no importance when revolving, inasmuch as the cut then must finish upon the line of centres—i.e, upon the straight line between the lathe-axis and the cutter-axis. Therefore, in the helicoidal thread the necessity for attention to centring with the revolving cutter is only in proporto the longitudinal component in the thread. With a traverse of ·1in., or thereabouts, this longitudinal component is so small that one must be very careless to get the revolving cutter discoverably wrong. The threads cut by myself have been examined by Mr. Evans and other experts. Mr. Evans once said that "no one had ever before cut such perfect screwthreads," and every expert who has seen these threads has approved of them.

I regret much to have had to occupy so much space in developing this matter; but when a writer like Mr. Wenham persists in reasserting these things it is necessary to set the facts out fully. There is no literature that I am aware of which developes this subject, and as it belongs to a difficult branch of descriptive geometry which is of great practical interest to mechanics, I trust that I shall be excused if I write a few words more upon the *normal section* of the screw-thread.

If we take a helix—*i.e., a spiral line—its normal helix*, where the two curved lines intersect, gives *a point*. But our triangular screw-thread is a triangular bundle of these spiral lines, and the points at which they will be cut by a rectangular normal helixoid will lie in the surface of that helixoid, and not in a plane as when cut axially. If, having cut a perfect angular thread upon a cylinder, we could take an infinitely thin tube and sever the whole thread from its base, we might contemplate the spiral thread in one hand and the cylinder which formed its stem in the other. The axial section of this thread would obviously have a straight line for its base corresponding to the straight line which the cylinder would give if cut by an axial plane. But, the inside of the thread being a hollow cylinder, every line except the axial one would be curved, and the curved line forming the base of the normal thread-section would be one of the spiral lines of the normal rectangular helixoid. It would be the normal helix taken on the surface of the cylindrical stem. This must be what "Vulcan" saw in his mind's eye when he wrote (page 60) "the axial section would be a curved broader-based one"; but then, at page 125, "Vulcan" writes:—"I find I have misstated the nature of the deformation: the thread would be broader-topped, not broader-based—it is the cutter which should be broader based." "Vulcan" has not yet thought out this intricate stereometry. Perhaps he will develop his positions more fully. What are we writing about?

We now see that the normal section of the screw-thread is that area of the normal rectangular helixoid which intersects the screw-thread, and that the base of the normal section is a length of the normal helix taken on the surface of the cylindrical stem. In no case, except that of severance from its base by an infinitely thin tube, would the thread shear from the substance of its stem on that line. The substance of the stem at the base of the thread is, for the calculation of stress-bearing capacity, as much a part of the thread as of the cylindrical stem. I am not prepared to discuss offhand the distribution of shearing stress around the base of the normal section; but, probably, if we took the chord of the spiral base line, we should be about right. **James Edmunds.**

Grafton-street, Bond-street.

## LATHE-MATTERS.

[24173.]—IN his letter on page 173, "Vulcan" says he does not wish to "poke fun" at me; but he is a little bit in the sarcastic vein. He says that my expression, "What I know, that I know," is impressive. I only meant that it should be impressive, and I have a sort of idea that it may leave a tiny mark perhaps. I wish to say, however, that it had reference to my letter (No. 24112) and its subject, and to none other. On the very same page on which "Vulcan's" appears, I admit that I sometimes "doubt," and, without question, I am sometimes wrong—who is not? I can only say that I use my best endeavour not to render retractation a duty, and am not now quite sure that I was wrong in the matter of friction.

As to "impressiveness," I have often in vain tried to impress on three generations of Mr. Evans's family what I perhaps too fondly think I may have succeeded in proving to the present one a little while ago—viz., that it is not only possible, but easy, to make chucks interchange on mandrels of the ordinary construction, provided only that both the noses of the mandrels and the thread in the chucks are properly cut. With the tools that our forefathers had—viz., taps and hand screw tools—it was simply impossible, and they were quite right in saying so, and in telling their children so, and hence few or none of those children ever made the attempt, and were content to leave it alone as an impossibility. I had many a talk and disputation with Mr. Evans's father and grandfather on the subject, and, of course, they looked upon me in those days as a young fool for daring to dispute their accuracy. When I was talking to the present Mr. Evans about it, at the beginning of the present year, or late in the last one, and I said, "I am sure I can do it," he was polite enough not to contradict me, but turned it off by saying, "Oh, yes, you can do it, but who (or nobody, I forget which) else can?" My assertion is simply this: that with well-cut screws a chuck will go right up to the shoulder, and centre itself accurately without a cone fitting; that if either of the screws is the least bit eccentric or drunk, the presence of the cone-fitting makes it less likely that the chuck will shoulder up, and that easing the screw to allow the chuck to go up is an unmechanical artifice, as it leaves a cross-strain on the screw itself. Or, summing up the total result, the cone-fitting at best does no good, and it may even do some harm.

I have, of course, nothing to say against cone-fittings without screws; for live centres fitted into hollow mandrels, or dead centres in poppets, for which they are more suitable than screws, I cone them 1½° on each side, or total 3°. The two mandrels that on February 9th I showed Mr. Evans, screwed end on into one chuck, were my own lathe-mandrel that has run about 15 years, and that of the milling machine figured Vol. XII., p. 185, November, 1870, and had no special preparation whatever for the experiment. As nearly as I can remember dates, I have "touched" 15 different mandrels during about nine years, and there are now two within half an hour's walk that I should dearly like to "touch," if their respective owners would only let me. I have had the job of making taps for the chucks of both, and found it a most aggravating task; yet one is a really good lathe—a Londoner—and the other cost over 200 guineas from an eminent country maker. The latter has about six noses that want "touching"—viz., mandrel, eccentric chuck, oval, dome, multiple screw-thread, and geometric chucks, and perhaps others.

I have been puzzled to understand the drift of "Vulcan's" letter (24157); but it just strikes me that it is all due to his misunderstanding my expression, "It cannot be done otherwise," which merely means that a screwing lathe, or some equivalent, is essential to the correction of badly-cut screws, leaving the choice of suitable tools entirely to the judgment of the artist.

J. K. P.

### LATHE MATTERS.

[24174.]—Having been away to the north, I have not seen the last two numbers of the English Mechanic in the usual time. My challenge for the production of a screw both cut and finished by a revolving cutter and grinder has met with no response, for there is no such screw to be found that would bear the reversing and counter-test for accuracy of thread. "J. K. P." truly remarks that "a cutter made for a screw of any particular number of threads will not do for any other number." This cutter is not a practice, and never will be. With this the subject may be dismissed."

Running over Mr. Hines's letter, at page 148, No. 1047, I find it pervaded by the usual tone of self-praise and desire to place himself first in rank as a lathe-maker. Thus: "As I have already said, every reader who has a fine ornamental lathe, made either by myself or by Holtzapffel, or Evans," &c. As to the last firms, we all read their interesting writings with pleasure, and, being practical and free from the trade element, are above criticism.

With respect to myself, Mr. Hines has got into the abusive stage. I cautioned him not to allow his pen to be guided. By this he incurs a double responsibility. He, however, puts the words "dodging about," and "runs away," as applied to myself in common. These are the now well-known coarse stock phrases of another hand, who, when his lack of practical knowledge is corrected, substitutes abuse for argument. Let Mr. Hines, as a self-styled practical man, continue to be "amused" at tempered mandrel noses, and announce that he makes his own soft. This is a losing argument for him, and I am content.

I have before remarked that I do not write to the English Mechanic on technical matters unless I have either practised or seen them myself. Does Mr. Hines really assert, or has he been led to suppose, that I know of no makers of lathes who in their workshops adopt diamond turning tools for their hardened steel surfaces, and, to use his elegant phrase, that I "make a paltry excuse" instead of naming them? This is a forlorn hope for him. I do know of this practice, and the lathes of the makers who adopt it well. I invited persons to obtain their names from me privately through the medium of these pages. This has been responded to, and I have the appropriate thanks in reply. These lathes are by Continental makers; the diamond-turned mandrels are beautifully finished. In the ordinary ones the old weak back centre is discarded, yet they run remarkably light. Every lathe is supplied with a standard plug tap or hob, the exact counterpart of the mandrel screw; a running catch-plate or pulley is also sent for turning up small work accurately between fixed or dead centres, and great attention has been given to make these lathes a really useful and workable tool. They would be selected in preference to those made by one of the assumed "first rank," particularly as they are sold at nearly half the price, and I intend ordering one of them for my own use. An old engineering friend of mine procured one for his amateur workroom, and is so satisfied that he has just got another with a traversing mandrel for fine screwcutting; and thus the conservatism, or I may say the obstinacy, of some of our old makers is causing the trade in small and fine mechanism to leave this country.

The English Mechanic is a first-class medium for communicating useful knowledge to its readers. Will Mr. Hines aid in this, take the onus, and request me plainly to give the names of these manufacturers? I shall be very glad to do so if the Editor will kindly permit it.

Passing on to Mr. Hines's note at p. 173 of last issue, first (not neglecting to insinuate matters as to the antiquity and leadership of his business) he shows that he has never used the diamond turning-tool, but his examples have been "hunted up" by his father, and had been used by someone even before him; and then says that diamonds "cannot be ground down to an effective edge upon a diamond lap, as Mr. Wenham thinks." Under the circumstances, the assurance of this assertion is rather astounding. I do not merely "think" about it. I have now in my hands a diamond tool sharpened to a cutting edge by myself years ago. I take this tool and use it on the hardest and harshest piece of steel—that is, an old file with the teeth ground off; with very little pressure it cuts and ploughs up the surface as if it were copper, not by a scraping action, but by shaving off the steel in lengths. Knowing what an unassailable material hard steel is, many persons would be surprised at seeing this. Mr. Hines states without knowledge that the "carbonado" is the only kind of diamond that will not break away. On the contrary, this is just what it does do, and therefore is not the best for making a tool with a fine cutting edge; its extreme hardness and the ease with which it can be powdered in the steel mortar makes it very suitable for charging laps and slicers. Then, again, to say that when the hard outer skin is gone a diamond tool is useless is another fallacy; cut or ground up diamonds may be used for drilling rubies, cutting agates, porcelain, or other substances much harder than steel. I believe this hard "outer skin" theory to be an error, arising from the fact that at first abrasive powders will not take a bite on a polished surface—for example, as emery on glass; we might as well say that this has a hard skin.

Do those who pretend to have used diamond turning tools and condemn them know how to mount and employ them properly? I imagine not. However, this we shall see. I intended to have given the result of my experience this way this week, but, as may be seen, I have been put under the necessity of doing some weeding, which has occupied my time.

F. H. Wenham.

---

[24175.]—Apropos of the discussion and correspondence on the "front slide lathe" some few months since, I have just noticed a drawing of a small bench lathe on this principle in the *American Machinist* for March 7th last, which I think would interest your numerous lathe correspondents if they have access to the journal in question; the design appears to be very neat and convenient in many respects. Two leading screws are shown, one for ordinary sliding purposes, and the other, which is of superior accuracy, but the same pitch, for screw cutting only. For some reasons this may be a better arrangement than the employment of a screw for screw cutting and a grooved feed-rod for sliding.

"B. Sc., Plymouth," 56443, should not put a round cord or gut on a flat wheel. I presume his flywheel has only one speed, in this case he can fix some wooden segments to the side of the wheel and turn V-grooves therein to suit his new three-speed V-grooved cone pulley on mandrel.

If, however, his flywheel has three flat speeds for belts, why not have a three-speeded flat cone pulley on his new mandrel?

Personally, I much prefer flat belts to cords or guts, as they can be run slacker than cords to transmit the same amount of power, and can be shifted from one speed to another far more readily.

Belts as used on foot lathes are rarely wide enough; a 5in. lathe should have a belt not less than 1¼in., and a 6in. lathe a 1¾in. belt. A narrow belt will never give satisfaction.

One great advantage of belts is that they compel the mandrel to be made of decent length. I was looking at some new light foot lathes the other day in which the distance from the end of the line centre to the middle of the collar was equal to, if not actually greater than, the distance from the tail of the mandrel to the same point.

I should mention that the centre was fitted into a chuck which screwed on the mandrel nose, an old-fashioned, abominable arrangement, of which the defects are only too obvious.

A. Myall.

### INTERCHANGEABLE MANDRELS.

[24176.]—If Dr. Edmunds's short cylinder does not act as centring agent, what use is it? And if it does, will it not drive the thread into closer contact at *one side* than at the other? I apprehend that the interchangeability would be perfect; but how would the lathe act with a stiff job and the poppet head not up?

An E.M.

### DIAMOND TOOLS.

[24177.]—In reply to A. P. Bower, I can only say that most probably if an attempt were made to abrade soft steel by a diamond charged skive or lap, the particles would leave this and get imbedded in the work. The same liability would occur in a less degree with hard steel. This cannot be effectively ground, shaped, or sliced with diamond dust. This without difficulty, will soon take a slice off a piece of hard quartz an inch in diameter, but to take a slice off the end of a hardened steel rod of this size would be an impracticable feat. The diamond particles get completely imbedded in the edge of the slicer, which also at once gets choked up by the abraded metal, and no longer cuts; but for its legitimate purpose it is not rendered inoperative by this, for now try it on the quartz with the usual lubricants. At first it is inert and quite slippery; but presently a little point catches the stone, and then the cutting action commences. The impalpable dust ground off the quartz acts by attrition on the unarmed portions of the edge of the slicer, laying bare the buried diamond, and no choking occurs, as with the hard steel. My lapidary mill or lathe is on the well-known Holtzapffel pattern, as I require the top or centres of the laps and buffs to be quite free.

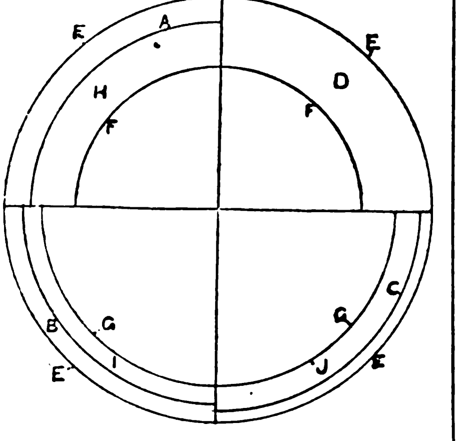
F. H. Wenham.

### HOW TO MAKE A VERY CHEAP LATHE-WHEEL.

[24178.]—Many who wish to build a cheap lathe would like to avoid paying 10s. or 12s. for a speed-wheel, when they could, by the outlay of half as many pence, and the exercise of a little skill, produce a wheel quite as heavy and almost as serviceable.

These persons, then, should take a smooth sheet of stiff, tough paper of sufficient size. Tack this by the corners to the wall, floor, dining-table, or anything you please that is flat, dear reader. Now take a beam-compass, which if you happen not to have—and this, no doubt, will generally be the case—can easily be improvised out of a square stick of wood, a bradawl, and a pencil. Bore a hole near one end, and of a size to hold the pencil tight when pushed through. The bradawl can be pushed through, at any number of inches from the pencil as may be required, to form the centre. With this describe the circle E, 13in. from the centre, and make a good clear dot on the centre. Take the paper down and cut out the centre very accurately; fold it carefully in half, exactly on the centre dot, burnish the fold well at its extreme edge, so that it shall give a well-defined and unmistakable mark when the paper is opened; but do not burnish to the extent of stretching the paper. Now open the paper, and fold it again in half, exactly on the centre dot, and so that the two halves of the first fold-mark fall exactly on each other. Rub down again, and open. Then describe semicircle F 6in., and G 9in. from centure, also A at 10in.; B at 11in., and C at 12in. respectively. Now take a sharp knife, or scissors, and cut out with great care the four pieces D, H, I, J. This is all that is wanted of the paper. Get a couple of orange, lemon, or onion cases, the ends and mid-partitions of which are made of ¾in. or ⅞in. beech or other heavy wood. Free these end pieces from nails, and see that they are not warped. Lay your paper patterns on the wood, and pencil off four pieces of each of the four shapes, D, H, I, J, 16 in all. The grain of the wood should run from end to end. Now saw them all out with as much accuracy as you possibly can. Just take half the pencil-line away with the saw. Attention to this point will save lots of trouble after in fitting. Plane up the ends of the pieces, if they need it, but recollect one end must be quite square with the other. Now draw a 26in. circle on the floor on which you intend putting the wheel together, and lay the four pieces, D, down in order with it. Drive a lot of nails round them outside (not through them), to keep them well in place. Place the four of J on these, so as to break joint; see that the inch space is equal all round. Fasten each of these pieces down with about eight 2in. French wire nails. Bore the hole carefully for each one with a gimlet or bradawl. Do not split the wood, whatever you do. If the wood is only ¾in. or ⅞in., these nails penetrate the floor a little. Never mind that; it will keep the work steady, and a little leverage will soon bring the wheel up afterwards. (The floor, of course, should be quite flat.) Now put on the pieces I, to break joint with J. Nail them on in the same manner with 2in.-nails.

The spokes must now be put in. (There is no boss or hub.) One-and-a-half inch stripes of the same lemon-case ends answer well. If four spokes be put, which is the easiest number (six would be, no doubt, better), they should be made a double thickness of the wood, well nailed together, with 1½in. left out half-way along, in one of the thicknesses in each double spoke, in order to rebate one into the other. Nail one of these first in its place in the wheel, letting its ends fall correctly on two of the joints between the pieces D, and having a regard to the future centre of your wheel. Now add the other pair of spokes. Two screws at every end would perhaps be better than nails. Now add the final pieces H, and, besides the 2in. nails, put in two wire nails to each quarter, long enough to reach right through the thickness of the wheel. Turn the wheel over, and hammer down the nail points, and put eight long nails through from the back. Bore all the holes, and do your best not to strike another nail. The hollow rim must now be packed as close as possible with pieces of old iron and dry sand and small stones, to fill the interstices. Fill one quarter of the hollow first, in doing which, of course, the wheel must be stood upright. Pack as much iron in as you can, and make the top level with the edges of the wood with old putty or paper; then well tack down a strip of tin or sheet-iron, long enough to reach from spoke to spoke, and as broad as the wheel-rim is thick, and then proceed with the other three-quarters. I have used old tin goods for packing, but they require to be cut or folded up (with hammer) in small pieces, and then packed on edge with a hammer and chisel, to get them to lie close. Now put two discs of iron-plate, 4in. or 5in. in diameter, one on each side of the wheel, to form the boss. Screw with two ¾in. screws to each spoke. If the whole has been put together with care, the spokes will cross exactly in the centre. However, find the actual centre on both sides by measuring from the outside edge of the wheel along the centre line of each spoke; mark the centre legibly, by twirling the pencil round on the point. Then take the compasses and draw a circle about this point on the spokes, a trifle larger than your iron discs, which I premise are quite circular, and have centres to them. Now screw the iron discs on so that the pencil-marks on the spokes are equidistant from edge of said discs, all round, and the centres of the discs will be the true centre of the wheel. There will now be a little "valley" left between the discs, between each pair of spokes. This may be with advantage filled with one corner of a square block of hard wood, glued (!) in with white-lead. Knock down close, and put a short screw through the disc into it from each side, and trim off the wood level with the discs. Fifteen or twenty discs of tin or sheet-iron might answer as well as iron-plate; but I have not tried this. The hole for the shaft must now be drilled, beginning on both sides, and meeting in the wood, and a key-way filed. In doing the latter, remember that one side of the wheel is probably heavier than the other. The wheel, therefore, may as well be hung, so as to avoid the crank stopping at a dead centre.



The nails and screws will be less likely to split the wood if they are made hot—just too hot to touch—before they are driven.

After the wheel is mounted, its edge may be easily trued with sharp files as it runs, and if wanted for a gut-band the V-grooves can be filed in the same manner. I will leave it to the reader to do as he likes about painting it. I do not claim for this wheel to supersede those of iron; but it will cost far less—at most only a few pence—and will weigh 45lb. to 60lb. A key-hole saw will be found convenient for sawing out the quarters. **Murano.**

## ENGINE-MAKING AT HOME.

[24179.]—In answer to "Invicta" (letter 24144, p. 169), I beg to refer to the article which he mentions for the reasons why I adopted the slide-bars in Figs. 1 and 2, in preference to those of Figs. 3 and 4. And while duly appreciating the extensive knowledge possessed by our correspondent, and the spirit in which his criticisms are offered, I still consider the guide-bars in the first figures better than the form which "Invicta" advocates. There is no special difficulty in fitting them up, and the bearing surfaces are ample. There is also the very important advantage of having the thrust of the piston rod transmitted in a direct line to the slide blocks, instead of to a point above. The consequences of a misfit are more serious in the dovetailed-shaped slides than in those which I figured, involving tipping and the wearing rounding of their faces and edges. They are quite suitable for large and slow-running engines, but not for small ones going at a high speed, and are seldom adopted for the latter. Neither is the use of a planing machine necessary to the fitting of the slide bars, as "Invicta" assumes. In the articles deposited at 332, Strand, I have endeavoured to give such instructions relative to the fitting up of the engine parts that those who are not engineers may be able to construct their models to the design of Figs. 1 and 2 without having recourse to a planing machine at all, and possessing only lathe, files, drills, &c.

An overhanging cylinder is advantageous, as keeping the moving parts low down on the bed; but I should hesitate to recommend its adoption, because, although there is less work in such a cylinder than in one with feet, the work on the bed is increased to a considerable amount, since the hooded end to which the cylinder is attached has to be cored out to form the inside of the hood, and the cylinder-cover and its stuffing-box. Not long since I made the pattern for such a bed for an engine of about 20 h.p., and in which the guide-bars were of the shape which "Invicta" advocates. A half-round print was boxed up sufficiently long to carry the core, and on this the stuff representing the thickness of metal in the hood was nailed, and its ends cut to the requisite curve. The print extended over about half the length of the guide-bar facings, so that half were on the bottom board of the box, and the other half on the pattern itself. There is no difficulty in making any of the combination beds now so much used, provided one has had an engineer's training; but they should not be attempted by amateurs. But the bed which is described on page 4 of the present volume is one which anyone could attempt and complete successfully, while its appearance is not inelegant.

If I have a preference for one guide over another, it is for that on Fig. 5; but I gave my reasons for discarding that. Still there is, I think, no better guide and slipper, especially when the latter is provided with wedge-shaped adjustment pieces. These and other things passed through my mind before I put pen to paper for the "Engine-making at Home." Out of the many types of horizontal and inverted engines I was at a loss which to select. Of course it was necessary to select some one form, and that, whatever it happened to be, would not meet with universal approbation. I have it in my mind to write at some future time a course of articles in which the history of engine development will be discussed, and the advantages of modern improvements in their various details taken up, and such a series would afford that scope for the balancing of various opinions which would be out of place in a merely practical series such as the present.

"Glatton" (letter 24145, p. 169) should know that the use of the word "eccentric" in contradistinction to "crank," is misleading. In the connection in which I employed the term "eccentric" (letter 24108, p. 147) it was perfectly legitimate, since it was used to indicate a motion not directly reciprocating. The words were—"The pistons are not moved by a directly reciprocating rod, but by an eccentric." There is essentially no difference between an eccentric and a crank: each term signifies centres of motion set eccentrically in relation to each other, the eccentricity being generally understood to be less in the case of the eccentric proper than in that of the crank, and as the throw of the connecting or piston rods in the three-cylinder engines is small, I used the term eccentric in much the same way as we employ the term in reference to the back-gear spindle of a lathe. Whether "crank" or "eccentric," I say "ditto" to "Glatton," having nothing in my mind beyond the common three-cylinder engine with the piston rods attached loosely to the crank "pin," and kept in place by means of two rings embracing their three ends. **J. H.**

## PATTERN MAKING.

[24180.]—The oblong holes for shifting the back spindle must either be enlarged, or the wheels bushed for a smaller spindle, or new wheels cast. You have no choice apart from these methods. If the metal in the lugs will permit, the holes might be enlarged, but they should be larger than the spindle to permit of the latter being fitted into a brass or steel bush at each end, the bushes forming the actual spindle bearings, and sliding on their outer or flat faces in the oblong slots in the headstock lugs. They are kept in place, when in or out of gear, by steady pins from the top. If your metal is not sufficiently thick to allow of this filing out of the holes, you had better bush the ends of the wheels with gun-metal or steel bushes, say ⅛in. thick, simply driving them in tightly with the hammer.

The size of the driving wheel may be 18in. or 20in. Say you make it 20in. on the longest speed, then your pulley being 6¾in , 5½in., and 4¼in. on its steps, the driving wheel should be 17¼in., 18¾in., and 20in., for the strap to fit on all alike.

**J. H.**

## MINERAL-OIL LAMPS.

[24181.]—I have read, with mingled feelings of interest and surprise, the remarks of P. Ward in a recent issue about the over-heating of the oil-container of the Silber lamp which he has, and of its having "blown up" several times.

Now, as manager of the Silber Light Company, I have used, experimented with, and examined a great many of the Silber lamps, and, amongst the many thousands made by the Company, I have come across a few defective ones, in which the over-heating of the oil-receptacle has occurred to a slight degree, but certainly nothing at all like that described by your correspondent.

As regards the "blowing-up" which P. Ward refers to, there is not a mineral-oil lamp in existence in which this phenomenon could not be made to occur under certain conditions, but these conditions are very abnormal indeed.

The fact of P. Ward's lamp having "blown up" several times points at once to its being a defective one, and it seems a pity that he has not acted, with regard to his lamp, as he would doubtless have done with any other defective article—i.e., returned it to the maker for rectification.

I must add, however, that the second part of your correspondent's letter reads somehow to me very much like a gratuitous advertisement of somebody's new burner. **J. Collins.**

[24182.]—The best oil is the cheapest. Common kinds give out great heat, and are dangerous. I have used a lamp with a glass receptacle for a long time without accident. Keep lamps very clean, don't carry them about, keep well filled, turn down gradually, and never blow them out. A swinging lamp is the safest, simply because it cannot be upset. A really good lamp is now to be had for about 2s. 3d. in the country; here in London we get them for 1s. 11d. The body is of white enamel with a shade of the same substance; the wick is circular. They burn but little oil, and, unlike some with this shape of wick, go out quickly on being turned down gently. I tried one after it had been burning all the evening, and found the brasswork quite cool, and even the lower part of the glass not too hot to hold. Lamps explode from the use of bad oil, accumulation of charred portions of wick, and gross carelessness generally. **R. W. J.**

## RAILWAY AXLES.

[24183.]—Since my letter upon the "Breaking of Axles" was written, the Board of Trade return, relating to the accidents during the year 1884, has been published. During that period there were 385 failures of axles, by which 24 passengers were killed, and 69 passengers and 4 servants injured. Of the 385 axles, 223 were engine axles—viz., 200 crank or driving, and 23 leading or trailing; 24 were tender axles, 6 carriage axles, 113 waggon axles; 19 axles of salt vans; 68 waggons, including the salt vans, belonged to owners other than the railway companies.

Of the 200 crank or driving axles, 138 were made of iron, and 62 of steel, the average mileage of

135 iron axles = 216,333 miles.
59 steel axles = 173,287 miles.

20th April. **Clement E. Stretton.**

## OLD LOCOMOTIVES.

[24184.]—The *Engineer* for October 10, 1879, contains a very clear engraving of the "Invicta" of 1830, copied from a photograph. The same number, in addition to a few other particulars, also contains the following information respecting it:—

The "Invicta" was exhibited during the Railway Jubilee at Darlington in 1875, when the photograph was taken. The engine was sent by Mr. Cudworth, of the South Eastern line, and was constructed by Messrs. Stephenson and Co.

In some respects it resembles the "Rocket" of 1829 celebrity: had inclined cylinders as in that engine, but these were placed at the funnel end over the front wheels, instead of at the side of the firebox as in the "Rocket." The four wheels were coupled, the trailing wheels being the drivers.

The furnace was cylindrical and placed inside, and behind the cylindrical boiler it was about 2ft. in diameter. From this furnace tubes extended (number not known) to the front, the arrangement being a cross between the old single flue and the multitubular boiler.

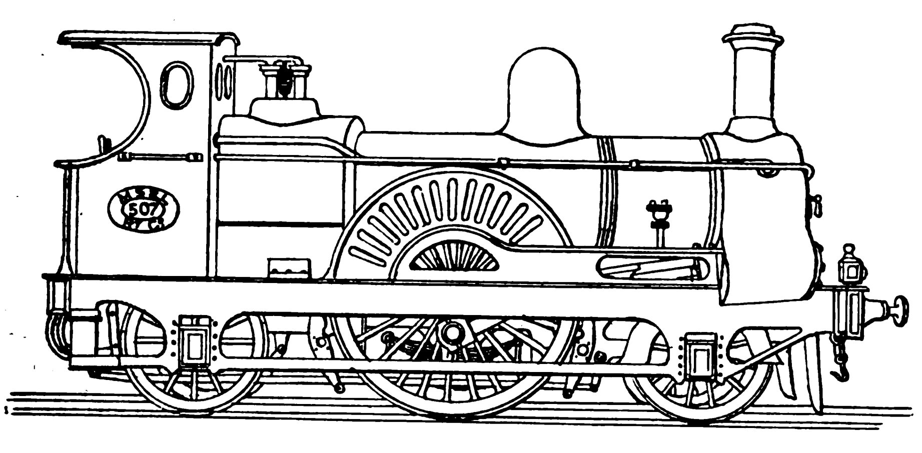
It is also stated that the existence of this engine has been passed over in silence by all historians of the locomotive.

The "Invicta" was much dismantled as exhibited at Darlington, and on account of its early date it would be extremely interesting if anyone could furnish the information as to what kind of reversing gear was fitted to it, as well as any further particulars which the dismantled remains of the engine cannot supply. **Telegraphist.**

### M. S. AND L. ENGINES.

[24185.]—Herewith I send sketch of the 7ft. 6in. single express engines on the M. S. and L. Railway, as asked for by "G. A. T." (letter 24120). These engines were designed by Mr. Charles Sacré, and commenced running in 1883. Dimensions and particulars have, I believe, been given in a previous issue; but I can forward same if required.

**W. H. Thurlow.**



### ANNEALED CASTINGS.

[24186.]—In answer to letter 24094 from Mr. Eaves, carburetted annealed cast iron is well known to those in the trade: hence my reason for advising amateurs in accordance therewith. I am aware that carburetted implies containing carbon; but it is a matter of controversy whether the malleability of the annealed cast iron is owing to the extraction of all the carbon or a molecular change within the iron itself.

The annealing of cast iron, or rendering it malleable more or less, is of much older date than is generally supposed.

Réaumer, in his work on the "Art of Converting Wrought Iron into Steel and of Softening Cast Iron" (*L'Art de Convertir le Fer Forgé Acier, et l'Art d'Adoucir le Fer Fondu*), published in 1722, gives numerous experiments by which he succeeded in producing malleable iron castings. He states, however, that these said malleable iron castings had already been made some twenty years before, but in a secret manner. Réaumer discovered that a plate of cast iron exposed for a long time to the direct action of a fire was covered with a coat of black and red oxide, and that the metal underneath had become softened (malleable). He collected this oxide for the purpose of packing with it small bars of white cast iron, and after heating them in covered crucibles he obtained a perfectly malleable iron. His other mixtures were powdered limestone and charcoal, or charcoal with calcined bone-dust. The first mixture is evidently that used at the present time; the second may be explained by the oxidising action at a certain temperature of the carbonic acid disengaged, which parts with an atom of oxygen to combine with the carbon in the cast iron, thus—$CO_2 + C = 2CO$. Or it may be that the carbon was burned out by the air of the fireplace penetrating through the interstices of the cast-iron plates forming the boxes in which the metal and the mixture were packed. The air was prevented from acting violently by the mass of bone dust and powdered charcoal with which the articles were surrounded.

It is evident that Réaumer ascertained that oxides of iron and cast iron heated together in closed vessels produced malleable iron; also that for malleable or annealed castings white is preferable to grey metal, and that castings previous to annealing should be deprived of the adhering sand, which, becoming fluxed, prevented the reaction, and that properly annealed articles may be bent, forged, welded, case-hardened, and present all the properties, and even appearance, of wrought iron.

Some authorities say that it is decarburisation by which cast iron is malleablised in this process; but Mallet doubts this, and remarks that by annealing white brittle cast iron either in hæmatite, chalk, or *even sand*, he obtains not so much a chemical change as a molecular change in its constituent particles.

Oxide of zinc has been proposed as a substitute for oxide of iron under the plea that the operation is more rapid.

The Siemens gas regenerative furnace is in use in large works. The castings are carefully packed as above, and are kept at a bright red heat for 80 to 90 hours, and allowed to cool down gradually in the furnace for about 30 hours.

More recently a patent was taken out by a Mr. Ramsden in 1881, No. 1874, for annealing, in which he states that he uses "a mixture of red ore and oxide of manganese or nitrate of potash and other materials."

If all the carbon could be extracted, the term "carburetted" as applied to annealed or malleable cast iron would be incorrect. This, however, is impossible. It should be borne in mind that the best quality of wrought iron contains carbon.

Mr. Eaves asks me what battery I used when testing the different armatures. I used a special form of Bunsen, containing sufficient liquid to do fifteen to sixteen hours' practically constant work.

**John E. Chaster.**

Talbot-street, Southport.

### LAMINATED ARMATURES.

[24187.]—Mr. F. Walker, in letter 24095, now states that 150 discs should have been 110. It would have been better if he had made this correction before. He says that he will make the 1in. of compression so clear that even I may admit the possibility, and then goes on to say that he threads the discs on to the spindle just as they come from the punching machine. I do not follow this *explanation!*

With regard to letter 24133, Mr. W. Habgood seems to have fallen by the wayside, along with Messrs. Walker, Harcourt, and Eaves, in supposing that I condemn laminated armatures for dynamos or motors. I state here most emphatically that I have never spoken or written against laminated armatures.

I merely called attention to an armature of inferior design that had been suggested for my motor during the time I was contributing the articles on electro-motor construction. This armature in question happened to be laminated, and because I condemned its use in the electro-motor, I am at once charged with having cried "Fire!" as far as laminated armatures are concerned.

If laminated armatures are so much better in these small motors, I wonder that the large makers of such who have doubtless tried them do not supply them. **John E. Chaster.**

28, Talbot-street, Southport.

### MYSTERY GOLD—USE AND TEST FOR.

[24188.]—The description recently given in the papers of this alloy, which is said to be used for making false sovereigns and jewellery, indicates that it might have a more legitimate use to replace platinum, carbon, or at all events, silver in batteries. I do not know where to obtain a sample; but if anyone can supply me with a piece I would try its suitability.

It is said to resist the usual tests for gold, and not to be attacked by acids. From its constitution I should think it might be distinguished from gold by its not being whitened by a spot of mercury, which test has, however, the disadvantage of defacing a real gold article to which it might be applied. But it appears probable that a weak solution of nitrate of silver might be a good test. Gold would not be affected unless very heavily alloyed; but I should expect to find that "mystery" would expose itself by a black mark of precipitated silver. **Sigma.**

### SEPARATE PEDAL ORGANS FOR AMERICAN ORGANS OR HARMONIUMS.

[24189.]—In my sketch, which appears on p. 171, I omitted to show the feeder spring of American organ bellows. If there is anything required to be explained with regard to the subject, I shall be pleased to answer any reasonable inquiry.

**G. Fryer.**

### MICROSCOPE CONSTRUCTION — LECLANCHE CELLS — REPAIRING BOILERS — GERMAN SILVER — CEMENT FOR KNIVES AND FORKS—FLAT EDGE LATHE WHEEL—AND RAIN-WATER PIPES.

[24190.]—I have referred to my previous communication on this subject, and fail to find therein even the ghost of the promise suggested by "Rob. Crus." But leaving mental aberration out of the question, it is only reasonable that a "Robinson Crusoe" should at times indulge in a little mild fiction. The remarks of "R. C.," and what he has accomplished, corroborate what I maintain, that any decent amateur can construct such an instrument as a microscope without a special series of papers other than what have appeared in the "E. M." Any maker of any importance has had his microscopes figured in these pages, and what more can be wanted. The glass grinding would certainly be an acquisition, as, although the subject of telescope lenses has, and is being well ventilated, we have heard little or nothing about microscope glasses, and we shall all be very glad to read what "R. C." has, to say on the matter, and to give him due credit for his doubtless original methods.

I can't say that the Leclanché cells of "Rho." are particularly cheap—batteries quite as good can be obtained from advertisers in this journal at about half the price, to say nothing of the time consumed in making them.

I wonder how "Invicta" would like to get inside a boiler with the steam just let off, as must have been the case with Lord Beresford's steamer. There are more easy ways to put a patch on a shot-hole than holding said patch up from the inside; doubtless, the engineer in question would tap holes in the shell and screw on a piece of plate. This, with some good packing, would prove equal in strength to any other portion of the boiler.

German silver *will* get tarnished (56431). I would recommend querist to try potassium cyanide. It is just possible that if the small articles were kept till wanted in petroleum oil they would retain their pristine brightness.

A mixture of powdered Bath brick and rosin is used for cementing knives and forks in their handles (56438).

I have a lathe-wheel with a flat edge on which a small round gut has been running for some years (56443), but you can't expect to get quite as much pull as the V-groove would give.

Mr. Ashworth (56446) can make an excellent joint in his rain-water pipe by getting a strip of tin plate about 2in. wide; bend this round the joint (a piece cut from an old tin can will do). This may be tied with a piece of twine or wire; now wind on some strips of canvas or calico, between the layers of which put plenty of red lead and linseed oil, and give a good coat of the same outside. This will, if done properly, last about as long as the pipe itself. Should be done in dry weather. **Os.**

### THE "CALORIE" IN FRENCH THERMAL UNITS.

[24191.]—I noticed in yours of the 27th of March last, p. 91, this was given as 22 British thermal units. Unless corrected, it may lead to errors.

The British thermal unit is 1lb. of water elevated in temperature 1° Fahr.

The French thermal unit is 1 kilogramme of water elevated in temperature 1° Centigrade.

Now the kilogramme is usually accepted as equal to 2·20462 British avoirdupois pounds, and the Centigrade thermal degree equals 1·80° Fahr. Then $2·20462 \times 1·80 = 3\ 998316$ nearly 4·00. In fact 4 may be used, as it so nearly approaches the true value, where French thermal units require to be used instead of British.

**Tubal-Kain.**

### NEW TIME.—DECIMAL TIME.

[24192.]—I have read the remarks of Mr. B. J. Hopkins on p. 151, and also those of "F. R. A. S." on p. 168, and am rather at a loss for a reply, for, as far as I can see, neither of those gentlemen has attempted to show why the change should be made, or to traverse the arguments of Sir E. Beckett. Any improvements which can be suggested in "Bradshaw's Guide" will doubtless receive attention from the publisher of that highly interesting work, which certainly is a bit of a puzzle until you get used to it, but not in connection with the times, only with the destinations and connections of the trains. I am bound to accept the statements made that people do get confused with the time tables, and so can only retort that if they make mistakes now, they may make more when the time tables are altered, which, however, is not likely.

I find that a Prof. Loudon has recently read a paper before the Canadian Institute, Toronto, Canada, in which, some time "after the fair," he suggests just exactly what "W. A. G." did on p. 341, last volume.

"The present day of 24 hours, on Prof. Loudon's system, would be divided into ten divisions, so that each hour, if we might so call it, on the new system would correspond to 2 hours 24 minutes. This hour would be again divided into 100 divisions, called minutes if necessary, each minute on the new system thus corresponding to 1·44 minute, a good fractional unit. Again, this new minute division could be subdivided for accurate measurements into 100 divisions, called seconds. The advantages arising from such a system would be: 1. The abolition of the so-called a.m. and p.m. nuisance—what has already been accomplished by the 24 hour system. 2. All the advantages to be derived from the adoption of any system based on our scale of 10—namely, the inconveniences arising from the continual use of vulgar fractions and the use of symbols for each unit in the ordinary affairs of life. 3. The fact that the time in hours and minutes (which for all practical purposes is sufficient) is indicated immediately by the clock. This is the most important advantage, because in the present system we have always to multiply by five before we know the time—thus 1 means five minutes past, 2 means ten, 11 means fifty-five past, or five to, and so on; and this would really overcome the great difficulty experienced by most children in learning to tell the time."

There are, I know, some children who are naturally obtuse, but I fancy the "great difficulty experienced by most children" is unknown to them. Some so-called teachers experience the difficulty, not the children. **Nun. Dor.**

## A NEW THEORY OF THE VOLTAIC CELL.

[24193.]—THE generally accepted theory of the galvanic battery (taking the zinc-copper cell for our example) is that the zinc decomposes the acidulated water, the hydrogen of which, by atomic substitution in the intervening molecules of $H_2O$, is transferred from the Z to the C, and there given off.

To many minds this is quite unsatisfactory, as it seems at best to be a compromise with difficulty. Why should the H atoms be given off at the copper plate instead of at the point where the O unites with the zinc?

If the theory which I shall now offer contains a germ of truth, it will blossom into fruition; if not, the world of science will be none the worse for a new thought. There is nothing so fatal to progress as a blind acquiescence in unproved theory. As examples of this mental petrification recall Helmholtz's theory as to the limits of microscopic vision, and the generally accepted hypothesis concerning the antipodal tidal wave, which any student of mechanics feels *instinctively* to be wrong.

In considering the action of a simple galvanic cell, consisting of copper-zinc excited with dilute sulphuric acid, I assume that the hydrogen arising from the decomposition of the $H_2O$ passes through the zinc (*i e.*, between its atoms) and connecting wire, and thence, when the circuit is closed, to the copper element, and is given off at its surface, which opposes the zinc. In enunciating a new hypothesis, I am aware that it must agree with observed facts.

We will first consider the spark. Considered in relation to the proposed new theory, it is caused by the partial chemical union of the fleeting H atoms with atmospheric air. Reasoning *à priori*, we should expect that a reduction of the normal pressure would enlarge the spark, and this is, of course, true. How will this hypothesis account for the phenomena of the spark in vacuum tubes?

It is very difficult to see why "energy" should expand in a vacuum; but that hydrogen atoms should conform to the law of Mariotte is a matter of course. When we consider the enormous volume of hydrogen occluded by so dense a metal as palladium, there is no difficulty in conceiving that copper and zinc may offer a path to this pigmy of the elements.

The cross section of wires of a given diameter contain a certain number of atoms peculiar to each metal. The number and shape and position of these atoms determine the resistançe to the passage of the hydrogen atoms. Each wire has its normal capacity; when this is exceeded heat is evolved. (The captious critic is requested not to inquire now what this manifestation known as heat may be—this must come later.)

How can this theory account for the decomposition of $H_2O$? It is well known that heat alone will cause the separation of this compound, and we have just seen that a conductor of insufficient capacity is rendered incandescent. So we have a perfect theory in this case. The H atoms, passing from the Z to C poles, split the $H_2O$ into its component parts, for the water being a *poor* conductor offers a great resistance to the passage of the H. atoms, and instead of being manifested as heat, it appears in the separation of the combined elements. That such separation is equivalent to the rendering latent an enormous degree of heat is evident to anyone familiar with the oxy-hydrogen blowpipe.

I will not further enlarge upon the capacity of this theory to explain known effects. My object is to give the "E. M." circle an opportunity to pursue what I believe to be a new line of thought, feeling assured that in the counsels of the many lies ultimate truth. To me there is more of probability in this new theory than in the old. I can conceive of a flashing train of atoms, potent with energy, traversing their inter-atomic path much more readily than I can assimilate the idea of *currents* of ——nothing.

I believe *all* natural phenomena capable of a mechanical solution, and that time will effect their solution on this basis. I have contributed this as a nucleus of a theory, and hope your readers will aid in adding to the structure. I am aware that a cloud of objectors will arise. I myself could easily show the weakness of many sides of the new structure; but I am more interested in building up than in throwing down at present.

**James L. Gordon.**

## PARAFFIN-OIL LAMPS.

[24194.]—I HAVE read with some interest the lecture given on this subject by Sir F. Abel as published by you on page 48; but am much surprised in regard to what was said respecting the volatile qualities of paraffin oil; and as Sir F. Abel's article is headed "Explosions in Paraffin Oil Lamps," I shall confine myself to this particular ingredient, without reference to any other of the hydrocarbons which, I admit, are far more dangerous and inflammable, but which yield no adequate return in respect to cost and safety compared with paraffin.

I have tested well-nigh a score of samples this last two years, to ascertain the volatile and other qualities of paraffin oil, and my mode of proceeding has been on so delicate a scale as to be able to tell to less than half a grain in any given time, and I find the average of the whole of the tests taken in a room of 60° temperature to be less than 1oz., or only 416 grains per square foot of surface in 24 hours, or 17·8 grains per hour per square foot of surface, and on comparing this with water in the same temperature, I find water to evaporate at nearly double the rate, or 32·9 grains per hour, or 790 grains in 24 hours. These figures, as before stated, are taken from one square foot of surface, and would have to be very materially increased before any danger could occur from paraffin. Then, again, it is not generally known that paraffin oil is not like spirits of wine, turpentine, or naphtha. You cannot set it on fire at ordinary temperature in the absence of other combustibles. A flame applied to its surface will dry it up to a kind of waxy residuum.

I don't pretend to teach those who know, nor do I write to pull to pieces what Sir F. Abel has advanced on this subject; but the general public who consume the greater part of the paraffin that is used know but very little of its nature or qualities, and my desire is that what Sir F. Abel advanced in regard to explosions in reference to paraffin lamps should not create any unnecessary fear or panic amongst those who use it, and especially the poorer class of people who, in their ignorance to the contrary, are apt to allow their fears to increase, and especially when such information comes from such high sources. I am sure no such fear need exist as to paraffin lamps exploding with anything like care. The whole surface of any lamp container is scarcely more than 1-6th of a foot, and if wholly exposed, it would require about a week of days and nights to lose 1oz. in weight. As to the higher temperature it attains while burning, the greatest danger, then, is a wick that is too narrow for the holder or casing. The container generally increases in temperature as the paraffin gets less, and especially when it is so far exhausted as to require repeated snuffing of the wick, for when this is so, the wick is little better than a dry ember lodging upon the top of the wick-holder, and it is by this cause and just at this time that so much heat is generated, that it is bound to travel downwards as well as in other directions, and should the wick at this time be too narrow for the casing, the flame will then follow the heat and creep down the wick right into the already overheated container, for the flame, if allowed, will, like ourselves, struggle hard for existence. There should be standard gauges for all wick-holders and for wicks, so that we might have them interchangeable, for I have now before me, while I write, several 1in. wicks, so-called; but there is a difference of over ⅛th of an inch between the widest and narrowest. Then, again, in the plaiting of the wicks, there should be a fixed weight per yard according to width, for the substance of the wick has much to do with the perfection of the entire lamp. A loosely plaited wick, as Sir F. Abel says, will draw up the oil to the flame more freely; but there is only a narrow limit as to looseness, for I have known loose wicks not to answer to the winding gear, and even to drop down suddenly when in use, and almost extinguish the light. A loose wick may feed the oil more regularly to the place of combustion; but there would be less than half the trouble with these lamps if the containers were recharged more often, and this also would very materially diminish the danger. When a wick requires snuffing, it shows at once that the oil has gone below the capillary powers of the wick, or, at least, below its power to raise up a sufficient supply, and the lower the oil gets, the more frequent the snuffing, and the more heat generated, and, therefore, refilling the container before this occurs would save the bulk of annoyances, and help to remove the bad repute these lamps bear. But, however well these lamps may be constructed, they are not good things to carry about, especially upstairs, or down cellars, or along draughty places unless the light is previously lowered. And now in regard to J. Hughes's letter (24023, page 82), I am surprised at his wonder at Sir F. Abel's recommending metal containers for paraffin lamps, and at his statement that it is at variance with practical experience. What are the containers used in stoves but metal, and the lights much nearer the containers than in the lamps? Then look at the optical lanterns: these, again, are all of metal, and for three years I worked optically several of the "Silber" lamps, all of brass, chimney excepted, and each lamp worked to its utmost limits and with but very little surrounding air to cool them down; in fact, I have myself been almost baked with the heat from them, and this of a cold wintry evening, and never had the slightest mishap with any of them. Then, again, there are thousands of street lamps in America consuming paraffin, and the containers to all of them are of metal. They are made by a firm which has a factory in New York and another in Chicago, and even if there were positive danger in using metal containers, the interposition of a washer of cork about ⅛in. thick between the burner and the container would prevent its descent.

I know of one firm which, even now, interposes a stratum of cork, but thinner than what I have stated; but as the connection of the burner is on the locking principle instead of screwing into the container, this cork is used to prevent the "creeping" of the paraffin through the joint. I should rather think that the makers have adopted the opal glass or earthenware containers rather for cheapness and variety, as well as profit, without any regard to the slight difference in conductivity.

Then we have letter 24127, from Mr. P. Ward, wherein he is full of the praises of "Martin's patent duplex." The lamp which I was induced to purchase of their make does not bear out what they advertise. Their circular before me states that this lamp will burn 18 hours, maintaining the same light throughout, without its being necessary to touch the wick. Now the lamp I purchased does not contain six hours' supply, and as to maintaining the same light throughout, that can never be accomplished where the supply depends entirely upon capillary attraction. J. Hughes, at page 82, says few wicks have a pull beyond 4in., and I can go further than that, and assert positively that the action, or "pull," is a declinining one in every such lamp in existence before the 4in. is reached, while in some lamps where the containers are more the shape of inverted cones, the decline begins after the first hour of lighting up. Now, I ask, How can a light maintain an equal brilliancy throughout when every half-hours' record shows a decrease in the consumption, and this is my experience with the very best made lamps. Now, Mr. J. Hughes's statement of a 4in. pull is in accord with mine, when I say that even Martin's lamp is subject to the same laws as all others, and as my lamp of their make is from 6in. to 6½in. from tip of burner to bottom of container, it exceeds the line or depth of pull by 2½in. I have tested them and a great number of others of the very best makers during the last two years—tested them for six hours at a time, and have taken a record of the consumption to the grain every half-hour, and of course those lamps which consume the most or give best or greatest light, show the greatest decline.

**G. R. Postlethwaite.**

## MUSICAL SCALE.

[24195.]—IN letter 24135, page 151, Mr. Hunt asks me to state what properties notes must possess in order to have the quality of being in tune. I answer that the properties depend on whether the notes are heard singly in succession, as in an unaccompanied air, or whether they form component parts of the chord of a harmonised piece of music. In the former case experiment shows that the notes, to be in tune, must be those of the melodic scale derived from the series of consecutive perfect fifths. In the latter, experiment equally shows that the notes must be those of the harmonic scale. Why it is that in either case these notes, and these alone, give to the musical ear the feeling of satisfaction which is expressed when we say that the notes sound in tune, is a mystery which we can no more explain than we can tell why one substance tastes sweet, another sour, another salt, or why one kind of light gives the impression of red, another of green colour. Nor have we advanced one step towards a solution when we have disconered a mathematical law regulating the external phenomena which produce the sensatory impressions. There is no *à priori* reason why a certain combination of harmonic sounds should be pleasurable rather than the reverse. We can only take note that such is the fact. It seems to me that what Mr. Hunt says about simple and complex ratios is beside the question at issue, which is one to be decided experimentally. He appeals to the experience of pianoforte tuners. That experience I claim as strongly supporting my case; for the tuner's chief difficulty is to abstain from tuning according to the natural or melodic scale, to which his musical ear constantly tends to make him revert. The pianoforte being essentially an instrument for the performance of harmonised music, the harmonic scale is the one to which it must, as nearly as possible, be tuned; therefore, in tuning each note the tuner adjusts its pitch with reference to that of certain other notes, which, for that purpose, he sounds along with it. But, in consequence of the limitation of the instrument to 12 notes per octave, he has carefully to avoid tuning to the exact harmonic intervals, and he shows his skill by giving just the necessary amount of avoidance and no more. The result is, or should be, that the piano is tuned to the scale of equal temperament, which is mostly intermediate between the harmonic and melodic scales. Of course the equal-tempered scale is not perfect, and the melodic one is positively bad for the production of good harmonies. I never asserted otherwise. But harmony in music I believe to be a comparatively modern and artificial development of the art. Melodies (and very beautiful ones, too, as, for instance, some of our old Scotch airs) were composed and became popular before the facts and laws of harmony were known—even before the melodic scale had acquired all the seven notes of our present diatonic. I am somewhat puzzled by Mr. Hunt's assertion that "no one has set any other values" on the fourth and fifth intervals than ¾ and ⅔. Even in his last letter, page 129, he implies that there must be two different values for the fifth interval D—A in the scale of C, by assigning two separate measures to the D. From D grave 0·9 to A 0·6, is, of course, a ⅔-interval; but surely from D acute 0·88 to the same A is another and a different one. But, perhaps, there is another A (omitted by Mr. Hunt) corresponding to the D acute, which will give the correct interval. The same ambiguity rests on the fourth interval D—G. Here it is the interval reckoned from D acute, which is the correct (¾) one. Are there two G's also corresponding to these two D's? Again, Mr. Elphick, page 37, expressly says that both the fourth and fifth intervals have three different values, according to the part of the scale in which they occur, and he states these values in fractions. There is another statement of Mr. Hunt's which is curious—namely, that the ear asks for a change of three notes to fit a scale for modulation into the next remove. Musicians are generally agreed that a change of one note is sufficient, except when the modulation is into the relative minor key, when two notes are changed in ascending passages. But musicians use chiefly the equal-tempered scale, and Mr. Hunt says the changeable notes are in the "composite" scale, which he has given on page 10, No. 1041; but he does not indicate the three notes in it that are to be changed for any particular modulation. Since writing the above, I have seen Mr. Elphick's reply to my correction of his mistake regarding the interval B—F. He now calls it the diminished or imperfect fifth; but as that interval is not what is known as "a fifth" either in melody or harmony, I think he might have acknowledged his error, instead of implying that in pointing out that the interval B—F is not a fifth, I am in opposition to "our good composers of the past," &c. To him, as to Mr. Hunt, I have only to say that although the harmonic or simple ratio scale is the correct one to be used in harmony, it does not give true intonation to pure melody, and that the melodic scale does. —*Proof experimental.* **W. Hardie.**

Joppa, 28th April.

---

The regulations made under the Metropolis Water Act make it necessary that lead pipes should be of the following weight:—⅜in. diameter, 5lb. per lineal yard; ½in., 6lb.; ⅝in., 7½lb.; ¾in., 9lb.; 1in., 12lb.; 1¼in., 16lb.

# REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

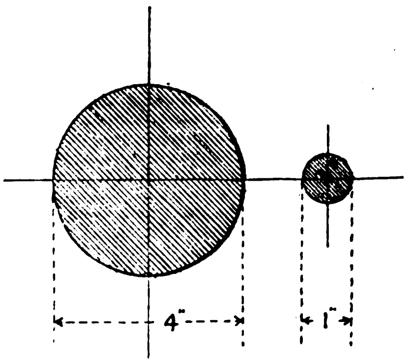
[53164.]—**3in. Spark Coil.**—I am very much obliged to Mr. Ernest Baugh for his reply, and will adopt his suggestion when I make my coil. Some time ago I thought of making one with discs of paraffiued paper; but, on testing a number of discs made in the manner directed in "ours," I found so moderate a spark would pierce them that I concluded I did not know how to make them sufficiently well to construct a coil with them, and therefore gave up the idea for the time.—B. Harcourt.

[54721.]—**Fine Adjustment for Microscope.**—On Sept. 26 I inserted a query under the above heading. This Mr. Lancaster asked me to repeat, which I did on Feb. 6. As he has not replied, will some other reader kindly help me, as I am anxious to finish the instrument?—Sempervivo.

[54825.]—**Salt, &c.**—"Dens" says "Backwoodsman" admits that wheat was choked off in the fifth season, &c. I suppose he spoke from America. As is well known, wheat is not indigeneous (native) to that country, so, of course, being merely introduced and acclimatised to America, plants native to America would, as being fittest to the surroundings, overwhelm and choke off wheat naturally. In my country, at all events, we have cereals wild in their natural state, such as wild oats and barley. Wheat is not a native of Germany, nor England, nor America; but, most probably, Africa, Asia, and Southern Europe, and if left there to itself, will propagate itself, and only deteriorate in quality. As is well known, cultivation will improve the quality, and often alter the nature of plants, trees, and animals. As to corn and baked cakes of bread having being found fossilised in the geological strata, I never heard of it before. Perhaps "Dens" can tell us when and where? I have read of fossils of bones of cave lions and hyænas, and also of stone hatchets found in river drift and caves; but never of relics of what can be called civilisation.—F. W. H.

[54825.]—**Salt.—Origin of the Cereals.**—Admitting that "Dens" may be correct in asserting that wheat will not survive one year in this country if left to itself, I would point out, that is not the question; for what we want to know is what the wheat of (blank) years ago did, and what it sprang from. "Backwoodsman's" evidence was a trifle more scientific than "Dens's" counter-assertion, and the "choking off" is exactly what one would expect, for plants developed by cultivation invariably run back when left to themselves, and are crowded out by more sturdy weeds. The origin of wheat has always been a curious subject of speculation to those who look a little deeper than the writer quoted by "Marienberg"; but the experiments of M. Fabre are generally held to afford strong evidence that wheat has been developed from a wild grass of Southern Europe and Western Asia, which the botanist calls Ægilops (see *Journal*, Royal Agricultural Society, Vol. XV.) It does not seem to have occurred to some that if a "special design" is accorded to wheat, it will be necessary to assume the same origin for rye, barley, oats, rice, maize, Eleusine, Bromus, Poa, Sorghum, Penicillaria, &c., all of which are staple food producers in different parts of the globe. It is much easier to believe that they have been developed by cultivation, just as we *know* that our modern fruits and flowers have been developed.—Nun. Dor.

[55700.]—**Strength of Shafting.**—In the "E.M." of April 24th, "Glatton," in reply to "One Ignorant," says: "The 6in. shaft comes out exactly nine times as strong as the 2in. one. I inclose a demonstration of the fact that the strength of a shaft varies as the cube of its diameter. Is not "Glatton" "at sea" here? For the assertion that he makes that a 6in. shaft is nine times as strong as a 2in. one, is not borne out by the fact that he professes to demonstrate; which demonstration he finishes up by saying: "That is, a shaft which is double the diameter of another, is four times as strong. In the same way it may be shown that a shaft three times the diameter is nine times as strong." Now, the demonstration that I inclose will, I hope, set "Glatton" right, and prove to him that the strength of shafts does vary as the cubes of their respective diameters. In the accompanying sketch, let Figs. 1 and 2 represent two shafts whose diameters are in the proportion of 4 to 1; then the strength due to the sectional areas is as 16 to 1. But the strength is increased by leverage in the proportion of 4 to 1; therefore the total relative strengths are as (4 × 16) 64 : 1, which is the proportion of the cubes of the diameters.—G. O. T.



[55700.]—**Strength of Shafting.**—Errata.—In my reply on page 174, in the last three sentences, for "four" read *eight*, and for "nine" read *twenty-seven*.—Glatton.

[55930.]—**Self-Winding Watches.**—In a memoir of M. Guinaud in the *Mechanics' Magazine* for 1825, Vol. III., p. 293, occurs the following paragraph:—"It was not until some years afterwards that an acquaintance of his, M. Recordon, having proceeded to England, where he obtained a patent for the invention of self-winding watches, which were then in great request, brought him (M. G.) from that country, some flint-glass." This visit of M. Recordon's was apparently between 1770 and 1780.—Murano.

[55957.]—**Stop Watch.**—Will "Englethwaite" please excuse delay in thanking him for reply to the above query? His idea is very ingenious, and quite applicable to the required purpose, save in one particular—viz., the reading off. As the pendulum moves with varying speed, the arc would require to have unequal divisions to indicate equal portions of time, and it is obvious that the reading could not be depended on to the required degree of accuracy if the pendulum was stopped near the limits of its swing. Can "Englethwaite" suggest any device for overcoming this difficulty?—Pendulum.

[56025.]—**Trueing Grindstone.—Patent Law.**—I reply to "Nun. Dor.," and so as to clear the ground, I give the exact words of the granting part of the patent, which is also prohibitory, and the actual words of the prohibition contained in the patent: "Know ye, therefore, that we, of our especial grace, certain knowledge, and mere motion do, by these presents for us, our heirs, and successors, give and grant unto the said patentee our especial license, full power, sole privilege, and authority that the said patentee by himself, his agents, or licensees, and no others, may at all times hereafter during the term of years herein mentioned, make, use, exercise, and vend the said invention within our United Kingdom of Great Britain and Ireland and Isle of Man, in such manner as to him or them may seem meet, and that the said patentee shall have and enjoy the whole profit and advantage from time to time accruing by reason of the said invention during the term of 14 years from the date hereunder written of these presents. And to the end that the said patentee may have and enjoy the sole use and exercise and the full benefit of the said invention, we do by these presents for us, our heirs, and successors, strictly command all our subjects whatsoever within our United Kingdom of Great Britain and Ireland and the Isle of Man, that they do not at any term during the continuance of the said term of 14 years, either directly or indirectly, make use of, or put in practice, the said invention, or any part of the same, nor in anywise imitate the same, nor make or cause to be made any addition thereto, or subtraction therefrom, whereby to pretend themselves the inventors thereof, without the consent, license, or agreement of the said patentee in writing, under his hand and seal, on pain of incurring such penalties as may be justly inflicted on such offenders for their contempt of this our Royal command, and of being answerable to the patentee according to law for his damages thereby occasioned." Now, I can assure "Nun. Dor." that the old proceedings at law used to state both the granting part and the prohibition, and the language used by the judges shows what I have said—viz., that the grant, "and none others," are words of prohibition. It has also been decided that to make a patented article for the purpose of experiment, and not for the purpose of using it for profit, is not within the grant or prohibition, and is, therefore, not an infringement. This is not a publication for a legal argument, or a reference to decided cases, but "Nun. Dor." will find that both Webster and Hindmarch's books treat the grant as a prohibition as well as the prohibitory clause itself; in fact, the words of the prohibition would not be large enough to prevent "making" or "selling"; as the words in the prohibition, as "Nun. Dor." correctly quotes them, are only "make use of," "put in practice," or "imitate." If you take the grant and prohibition together you have prohibited by exclusive "grant" and by express prohibition "making," "using," "exercising," "vending," "make use of," "put in practice," "imitate." I think I have thus shown wherein "Nun. Dor." is wrong. He ignores the prohibition in the grant that the patentee *and no others*, without license, are to "make, use, exercise, or vend."—A. P. Bower.

[56041.]—**Gun-metal.**—No, I am not inclined to split that hair about gun-metal and metal for guns; but until corrected I shall assume that gun-metal was originally the bronze used for making cannon—otherwise, whence the name? I know the gun-metal of the shops; but I doubt whether those who sell it are really acquainted with what it contains. Will some Woolwich reader tell us what is recognised there as ordinary gun-metal? I have heard that it is copper 8 or 9 to tin 1, or copper 16—18, tin 2½. In Hunt's edition of Ure's dictionary the only remarks under the head of "Gun-metal" are contained in a few lines about Aich metal, which is composed of copper 600, zinc 382, iron 88 parts. Under "Alloy," a gun-metal is mentioned composed of copper 90·300, zinc 9·670, and tin ·03; while bronze for cannon is said to be composed of copper 9, tin 1. Now, if any one likes to contend that the last is the true "gun-metal," why that settles the point so far as he is concerned; but if a carefully made specimen of good gun-metal of that brand is examined by the analyst, I believe he will find more than a trace of iron in it. For this reason, that "when bronze (*i.e.*, copper and tin) is melted in a cupola where a few fusions of cast iron have been previously made, its quality is sensibly improved. This result is due to the alloy of a small proportion of iron with the bronze." That is from Guettier's "Manufacture of Metallic Alloys," a work which, so far as I can find, never mentions gun-metal, but speaks of "bronze for cannon." In Knight's "Dictionary of Mechanics" (Cassell), there is a table of "Brasses and Bronzes containing Iron," from which I find that Stirling's gun-metal (patent 1846) contained copper 50, zinc 25, iron 1 to 8; Keir's metal (patent 1779) contained copper 100, zinc 80, iron 10; Rosthorn's gun-metal (Austrian), copper 55, tin ·83, zinc 42, iron 1·77. Knight quotes a number of analyses of ternary and quaternary alloys containing iron, and says "An English work of 1853 [slightly indefinite, that] cites the addition of one to two per cent. of iron to brass to give strength and sonorousness; and further states that large guns, large screws, propeller vanes, mill-brasses, railway bearings, bells, and other articles are made of a metal in which copper, zinc, tin, and iron all take part." In Spretson's "Casting and Founding" (Spon) gun-metal is said to be 80 to 83 parts of copper, 20 to 17 parts of tin. Overman, in his "Moulder's and Founder's Pocket Guide," says, that "if tin-plate scraps are melted in a crucible together with tin, and then this tin and iron alloy added to the melted copper, it will unite readily." Finally, from Percy's "Metallurgy: Iron and Steel" (Murray), I learn that sterro-metal was accidentally discovered in attempting to apply the ferriferous alloy of zinc, obtained in the process of galvanising iron, to the preparation of brass, and our distinguished metallurgist further gives the process of mixing the copper, zinc, tin, and iron, as supplied to him by Baron Rosthorn: "The iron, which must be malleable iron, is put at the bottom of a crucible with the copper upon it, and then exposed to a very high temperature. It is thus completely taken up by the copper, and when the whole is fused the tin is added and afterwards the zinc." Having thus occupied a good deal of space, I may perhaps be permitted to refer to the original query, p. 19, in order to show that at least one other person seems to be aware that gun-metal is not exactly a definite and invariable article of commerce, for the querist asked for the percentages of the different metals necessary to produce gun-metal that will resist the effect of a 3 per cent. solution of sulphuric acid. If anyone can answer that question, he will impart more information than I have been able to give.—Nun. Dor.

[56082.]—**Telephone Transmitters.**—Would Mr. Chaster oblige "Stubs" by giving a sketch and description of Hunning's form of transmitter mentioned by him, mentioning whether it works with Bell's telephone?—Stubs.

[56110.]—**Mill Bills.**—I have not had any experience with above; but as "Essar" seems to hold in contempt the additions of salt, &c., to the water used for tempering purposes, I should like to say a word or two. A short time since, not having a little water handy, I tempered a drill in the soldering solution, and was so much pleased with the result that I now temper all my small tools in sol. chloride zinc. I find a marked improvement in drills especially: they stand much better, and keep their edges longer. The only explanation I can arrive at is this: in pure water steam is formed at a lower temperature; the addition of a salt raises the boiling point; there must be less steam formed in a given time between the hot tool and the cold water, in consequence of which the cooling is performed more quickly. I am aware that the heat-conducting power of water is almost nil; but may not the addition of large quantities of certain metallic salts improve it? Such small quantities as 2oz. or 3oz. to 1 gallon of water must, however, be quite useless.—Zinc Sulphas.

[56140.]—**Ozone Bleach.**—Is this anything more or less than peroxide of hydrogen?—full particulars of which can be found in back volumes.—A. K. C.

[56145.]—**Wimshurst Machine.**—This query is one of that peculiar variety which appear to proceed from people who have no notion of helping themselves. The description of the "symptoms" is puzzling, to say the least of it, and it would be necessary to see the machine to give useful advice. The querist can help himself by reading up what has been written in back volumes from XXXVI. onwards. The querist constructed his machine "from descriptions given in the papers"; whether the "papers" are at fault, or his workmanship, remains to be found out.—Nemo.

[56149.]—**Calorimeter.**—This querist cannot do better than make his choice from Ganot. What does he think would answer in place of mercury?—J. C. T.

[56157.]—**Edison's Electric Pen.**—The patent was taken out in October, 1875. The £50 stamp was paid on Oct. 22nd, 1878, and the £100 stamp on Oct. 19th, 1882; so that the patent will not expire until Oct., 1889. The validity of this patent is still unchallenged. What "R. E. G." refers to I believe to be a patent of Edison's for microphones, in which he (Edison) claimed also the phonograph. This latter has been disclaimed, in order that the former may continue good.—John E. Chaster.

[56157.]—**Edison's Electric Pen.**—This query should be put to a patent agent, or to some one who can spare the time to go to the Patent Office and ascertain whether or not the patent has become void. The mention of "renewal," however, leads to the suspicion that the querist means the American patent. If so, things are dreadfully mixed, and the querist will perhaps say what it is he wishes to know. I think he will find it was the phonograph that was mixed up with the telephone.—Nun. Dor.

[56158.]—**Injector.**—I would suggest that the patentees of this injector would gladly give every information, for if it is to be fitted to a boiler by some one who does not understand it, I should not be surprised if it goes wrong.—Essar.

[56159.]—**Model Engine Boiler and Boat.**—The boiler described on page 153, in reply to query 56240, would be about right for your engines, which, by the bye, seem to me to be decidedly out of proportion as regards the height (11in.) compared to the cylinders. The boat should be about 5ft. long, 9½in. beam, and 9in. deep inside, built of XXXX tin strips about 1½in. wide, and soldered on a wire frame properly set out to the shape of the intended hull. Some builders of this description of hull strike up a wood mould and lay the strips to this, and then solder. Wooden hulls for steamers are not of much use, as they in time warp, crack, and get charred with the heating and cooling of boiler and fire. Boat-building of this description could not be gone into details without taking up a great deal of space in this paper, and I hardly think it would be of sufficient general interest to warrant such a description, or should give a description of one of the several splendid racing models I am intimately acquainted with.—S. Austel.

[56162.]—**Model Footplates.**—If I understand Mr. Shakespear, some of these are done with a file, others with a tool in the planer.—J. M.

[56164.]—**Applegarth Battery.**—In some forms of the batteries manufactured by Mr. Applegarth there is a central rod of carbon round which adheres a depolarising mixture, which I suppose to be peroxide of manganese and carbon. This is enveloped in felt and inside a cylinder of zinc, the whole being placed within a porcelain or other cell. The charging solution being a saturated or strong sol. of sal-ammoniac. If this be the form that Mr. Colley has, he should first see that the zinc is in good condition and well amalgamated, then, secondly, recharge with a fresh solution as above, having previously well washed the battery out with hot water. If this does not mend matters, he may be sure that the agglomerated block of carbon and surrounding mixture requires replacing. This can only be supplied by the maker or his agents. If, however, the battery be one of Mr. Applegarth's newer forms, in which the zinc rod is suspended from the cover, and the said zinc being within a carbon-containing vessel, forming as it does the negative pole—in this form the battery may be recharged by a saturated solution of sal-ammoniac. In this battery there is no attempt to prevent polarisation by chemical means; but owing to the very large carbon surface as compared with the zinc, this battery for ordinary bell-work, or wherever a constant current is not required for many seconds at a time, acts admirably.—John E. Chaster.

[56166.]—**Damp Workshop.**—Is this querist quite certain that the roof does "let the rain through?" What with his planking, his tar, asphalte, cement, &c., if the roof does let the rain through, he must have done the work in a very peculiar manner. Does the rain "pour" into the workshop, or is it condensed vapour which drops down from the roof?—Cyrax.

[56169.]—**Spectacle Lenses.**—The D in the formula means "dioptrics," the + convex, and − concave. The dioptric is Prof. Donders' unit—viz., a lens with a focal length of one mètre, and corresponds to the old 1-40th. Thus 4 D corresponds as nearly as possible to the 1-10th or 10 English inches. The querist will do well to take advice that in selecting spectacles it is as well to drop one's likeings, and allow an expert to settle the matter. Nowadays pebbles are only superior in that they are lighter, thinner, and harder. Pebble or rock crystal is readily distinguished from glass by its greater coldness to the tip of the tongue.—Nun. Dor.

[56172.]—**Locomotive Mechanics.**—We have any amount of interminable discussions about interchangeable mandrels, but no one seems to take notice of a really practical query like this. I have not had any experience with locomotives; but I should say that it would not be necessary to lengthen the back-gear rod when shortening the forward one—the link would make that right. What do our mechanics say, or are they frightened by the long words of the lathe-treadlers?—Centrebit.

[56173.]—**New Battery.**—If this querist will say what it is he really wishes to know, I will endeavour to help him. He appears to be acquainted with the fact that the Pabst cell is made with carbon and wrought-iron plates dipping into a solution of ferric chloride, and yet he asks "how to make."—Nun. Dor.

[56173.]—**Pabst Battery.**—To "F. Q."—This battery was patented by Dr. Pabst in England in 1883. The inventor claims: 1st. Elements of carbon and tin in a 10 per cent. ferric chloride solution or stannic chloride solution. 2nd. Elements of carbon and iron in an 8 to 14 per cent. ferric chloride solution. 3rd. Elements of carbon and iron in an 8 per cent. ferric chloride solution containing 4 per cent. of stannic chloride. To prevent polarisation, the inventor states that "This invention has for its object to employ atmospheric oxygen for the purpose, and consists in the employment as the electrolytic liquid of the aqueous solutions of the chlorides of such metals as form two compounds soluble in water corresponding to the oxide and suboxide. The higher chloride is reduced by the metallic electrode to the lower degree of oxidation, and again becomes oxidised to the higher degree by the absorption of oxygen from the atmosphere. The electrolytic liquids thus act continuously. . . . The ferric or stannic chloride solution being acted on by light, it will be preferable to blacken the glass vessel in which the element is contained." The difficulties that present themselves are first the small E.M.F., which I have seen stated as low as 0·5 volt per cell, and as high as 0·78 volt. Which is correct I cannot say; but even if the highest of the two be right, it will take 5 cells of the Pabst type to replace 2 cells of the bichromate or Bunsen type, a very serious objection when it is desired to light an incandescent lamp or run a motor. Again, the battery becomes crusted up with oxide of iron, and this oxide requires constantly to be taken out. Finally, the cells must be well protected from the light, as, if allowed out in daylight when working, a considerable amount of chlorine gas is given off, which is not, to say the least of it, very pleasant in, say, a ballroom.—John E. Chaster.

[56174.]—**Dioscope.**—Here's another! Look up the indices under Telectroscope, and search for the origin of these scientific tarradiddles somewhere in New York or New Zealand.—Nun. Dor.

[56176.]—**Patent Annealed Iron.**—Surely there is some mistake about this. Where did "Melbourne" hear anything about patent annealed iron, and annealing chilled castings?—Essar.

[56190.]—**Clark's Gas Lamps.**—Should think the best way to obtain the information desired would be to inquire of the maker.—Silica.

[56191.]—**Electrotyping.**—Does this querist want to make an electro of a wood block, or what? The usual method is to take a squeeze of the wood block in moulding compo., plumbago that carefully, and deposit a "shell" of copper. The shell is afterwards heated, tinned, and filled up with an alloy resembling type-metal.—Nun. Dor.

[56192.]—**Mineral.**—I cannot say I recognise the mineral from the description; but it may be achmite or ægerine.—G. H. B.

[56193.] — **Eccentric and Oval-Cutting Chuck.**—Does this querist really mean a "working drawing," or only a sketch which will enable him to make one? If the latter, he will find Mr. Evan's description of the oval and eccentric chuck in Nos. 850, 857; Nos. 886, 887 also contain drawings of oval chucks.—Centrebit.

[56195.]—**Consumption of Coal.**—In the last volume, it was stated that the *Oregon* consumed only 268 tons per day; other figures made it 300, but of course something depends upon the quality of the coal. As a rule, these large steamers consume 2lb. per hour per i.h.p., and, knowing that, you can readily calculate the daily consumption.—ESSAR.

[56197.]—**Rusty Water.**—This water must have been rusty indeed to quite unfit it for use. The pipes ought to be kept full of water always. You might do something by running them full with lime cream, stopping up the outlet of course, and letting the lime act for a few hours.—ESSAR.

[56199.]—**Nickel.**—According to our friend Mr. Bottone, quoted in Miller's "Chemistry," nickel is harder than either iron or copper, the figures given in Miller being nickel 1,410, iron 1,375, copper 1,360. I do not know nickel bronze; but if it is argentan, packfong, it can be made harder or softer by using differing proportions; but it is usually done by rolling and hammering to harden and by heating to soften.—NUN. DOR.

[56201.]—**Fixing Battery Plates.**—"Mikros" should use the new metallic plate connections, as manufactured by Mr. Lee, 76, High Holborn. These readily allow of the zincs being removed for amalgamation, and with the fluted carbons (giving double area), also supplied by Mr. Lee, enables one to construct a battery, the nearest approach to perfection of anything I have seen. If your battery is of the bichromate type, use the New Double Bichromate Salt, as it is cheaper than the bichromate of potash, and has many advantages. See also my reply to 55916.—JOHN E. CHASTER.

[56202.]—**Clock Gongs.**—Full directions for making and tempering clock gongs in No. 976, p. 311.—NEMO.

[56210.]—**Electro-Plating.**—To "ONE IN TROUBLE."—This is a somewhat difficult task to advise you without knowing the exact state of your bath. Dr. Gore states: "If the liquid is too dense, the articles still, and deposition is rapidly occurring, the goods are liable to become covered with vertical streaks, and to receive a much thicker deposit upon their lower parts than upon their upper ones. If the density is due to foreign salts, crystals of those salts are liable to form upon the articles in cold weather, and spoil the deposit. The specific gravity of a cyanide plating solution may vary from 1·036 to 1·116 without detriment to the quality of the deposited metal." My own experience in depositing silver is to use a somewhat dilute bath, and keep it at a temperature of about 65° Fahr. (do not let it get below this temperature). Never have too high E.M.F., and take care that the current is just enough to do the work. Don't push the electro-deposition of silver, and lastly, keep the work gently moving.—JOHN E. CHASTER.

[56215.]—**Nickel.**—I am afraid Mr. Tweedale will find this impossible. Nickel is not an easy metal to deposit nicely. In the first place, the chemical methods of applying silver to glass will not permit of nickel being substituted in place thereof. Secondly, nickel will not take kindly to silver, providing there is already a film of such metal. If the nickel were required bright, it is certain that it would never stand the polishing, as this metal is extremely hard compared with silver, and the poor hold the nickel would have, would immediately cause the metal to fly off in scales.—JOHN E. CHASTER.

[56228.]—**Storage Batteries.**—The information given by "Toby" might answer your purpose admirably; but I gather from your query that you are desirous of having a portable battery, and one that can be carried about in the pocket. If so, the single-cell battery, as described by "Toby," would not be sufficient, as you would require two such, if not three, to get the E.M.F. according to the lamp. If you would say what c.p. of lamp, and how long you require same to run at a time, I can advise you. All these pocket accumulators are, however, frightfully extravagant, in that they take three or four Bunsen cells two or three hours to charge, which will cost 1s. at the least for material consumed. The accumulator when charged will give a three c.p. light for about one hour. Why not use a pocket primary battery? Such a one is made by Mr. Lee, 76, High Holborn. This would fulfil all your requirements, and will not cost more than ½d. an hour, or twenty-four times less than an accumulator, to say nothing of trouble and temper saved.—JOHN E. CHASTER.

[56230.]—**Submarine Light.**—Living as I do by the sea, and amongst a somewhat extensive fishing industry, I know full well the advantages that a submarine light would be, especially during the autumn nights. I have never, however, heard of any such light as "Trawler" refers to. As to an electric light, I am sure an arrangement could be made that should neither be too costly nor cumbrous. I will give this matter my earnest thought, and if "Trawler" should be a near neighbour of mine, I should be ready at once to go further into the subject. Any question he might ask in "Ours" will receive my immediate attention.—JOHN E. CHASTER, 28, Talbot-street, Southport.

[56239.]—**Filtering Acids.**—Perhaps the acid, which you do not name, dissolves the cotton wool. A precipitate naturally does precipitate (else why call it a precipitate?), especially in a filter where the liquid in which it is suspended is passing downwards. The precipitate tries to go with the liquid; but as the filter stops it, what is the poor dear to do but stop on (and up) "F. G. S.'s" filter? Remedy: Could you not precipitate before filtering? I should think slagwool would answer for filter; only twopence per pound ready for use. Asbestos is, I believe, not less than one shilling, and then requires opening.—MURANO.

[56240.]—**Tug.**—I regret that in replying to this query, I accidentally left out one of the most important points in the construction of the boiler—viz., the stays for the firebox. These should be of No. 18 Stubbs W.G. copper wire, and disposed so that at least four will be on every square inch of the curved surfaces of firebox.—S. AUSTEL.

[56244.]—**Skrivanoff Battery.**—The receipt for charging this battery given by "Bobadil" is for the earlier form of battery patented by Skrivanoff, and only suited for bell work and testing. I take it that what "Accumulator" requires is the more recent patent in which chloride of silver is used as the depolariser in place of the oxide of copper of the Lalande-Chaperon cell. This cell is composed of a negative pole of silver, surrounded by chloride of silver, a zinc pole, and a 4 per cent. solution of either caustic soda or potash. The battery is well spoken of on paper, though I am of opinion that it will never come into large use. To dissolve 1lb. of zinc in the battery, there will be required 3lb. 5 z. of chloride of silver, which, at 3s. per ounce, represents a value of £7 19s. The capital required to make and maintain is decidedly against it, to say nothing of the loss of silver chloride that must be incurred in transforming the metallic silver obtained back again into the chloride.—JOHN E. CHASTER.

[56259.]—**Skrivanoff's Dry Battery.**—See reply to 56244. The dry battery is of no earthly use for your purpose. The number of cells required in series will be from three to four to light your lamp. See also reply to 56228.—JOHN E. CHASTER.

[56265.]—**Lalande-Chaperon Battery.**—A 20 candle-power lamp will require 60 watts to light it. I will assume the 20 candle-power lamp to require 45 volts; therefore you require 45 volts and 1 33 ampères. The Lalande-Chaperon battery gives, in my hands, 0·6 volt per cell; therefore, to get 45 volts, you require 75 cells in series. Now as to the size of cell. Experiment has repeatedly proved to me that not less than 40 sq. in. of zinc surface are required when the zinc is parallel to the copper or iron (as in the horizontal form), and separated from the copper or iron by a distance of not more than 1½in. To obtain 1·33 ampères, you will require 54 sq. in. of zinc surface. Therefore, if you make 75 cells each of about 8in. by 7in. and 2in. deep, and on the bottom of each cell place about 1½ to 2lb. of oxide of copper, then suspend a zinc plate so as just to go inside without touching the copper or iron, when all the 75 cells are joined in series, you ought theoretically to light your lamp; but practically you will require from five to ten more, owing to fall of potential. Use a 30 per cent. to 40 per cent. solution of caustic soda. This is made by dissolving in every 30lb. of water about 9lb. of strongest caustic soda. The whole battery should be protected from the air, as the solution of caustic soda by absorption of carbonic acid therein contained rapidly becomes carbonate of soda, and therefore useless. Any further information I shall be most happy to supply.—JOHN E. CHASTER.

[56301.]—**Flower Pots.**—To "POTTERY TECH."—Flower pots are set in the kiln in bunches; that is, one pot put in another till you come to the smallest pot, then chequered up in the kiln around and around till your kiln be full, or coupled up tops to tops and bottoms to bottoms, like stacking round blocks of wood end to end. The time of firing dedends upon the nature of the clay. If it be clay that burns red, "Pottery Tech" will have nothing to do but put a bit of glaze upon a pot on the top of kiln. When that runs freely his pots are done, which he may know by leaving a deep hole in the crown of kiln.—S. ABLIDGE.

[56331.]—**Packing Flue-Pipe Hole in Roof.**—Could you not make a gland round the pipe and pack it (i.e., stuff or ram) with asbestos or slagwool (otherwise silicate cotton) and white-lead, with a little oil? Red-lead would be better. If you care to try slagwool, I will send you sufficient (gratis) by post if you would like to have it, and will advertise your address.—MURANO.

[56335.]—**Potter's Kiln.**—I think J. Townley had better build a round kiln. Will he say the nature of the clay—whether it will stand much fire or not? Then I will try to help him.—S. ABLIDGE.

[56309.]—**Parallaxes of Stars, &c., Place of Spica A.D. O.**—To answer Mr. Arkwright's query would take up far more space than the Editor would be willing to allow. The following is a list of all the stars whose parallaxes have been found by trustworthy observers and methods to exceed 0·10″

| Star | Mag. | Parallax. |
|---|---|---|
| $\alpha$ Centauri | 1 | 0·75″ |
| $\alpha$ Tauri | 1 | 0·516 |
| Lal. 21185 | 7½ | 0·501 |
| 6 Cygni | 6 | 0·482 |
| 61 Cygni | 5½ | 0·478 |
| Sirius | 1 | 0·38 |
| $\mu$ Cassiopeiæ | 5½ | 0·342 |
| Groombridge, 1618 | 6½ | 0·32 |
| Groombridge, 34 | 8 | 0·307 |
| $\alpha$ Aurigæ | 1 | 0·305 |
| Lac. 9352 | 7½ | 0·285 |
| Lal. 21258 | 8¾ | 0·271 |
| Œltyen, 11677 | 9½ | 0·265 |
| ,, 17415 | 9 | 0·247 |
| $\delta$ Draconis | 4½ | 0·246 |
| $\varepsilon$ Indi | 5½ | 0·22 |
| Bradley, 3077 | 6 | 0·205 |
| $\Sigma$ 1516 | 7 | 0·199 |
| $\alpha$ Geminorum | 2 | 0·198 |
| $\alpha$ Lyræ | 1 | 0·179 |
| $o^2$ Eridani | 4 | 0·166 |
| 70 Ophiuchi | 4½ | 0·162 |
| $\eta$ Cassiopeiæ | 3½ | 0·154 |
| $\varepsilon$ Eridani | 4½ | 0·14 |
| $\iota$ Ursæ Majoris | 3 | 0·133 |
| $\alpha$ Boötis | 1 | 0·127 |
| $\gamma$ Draconis | 2 | 0·127 |
| $\alpha$ Canis Minoris | 1 | 0·123 |
| Groombridge, 1830 | 7 | 0·113 |
| $\alpha$ Ursæ Minoris | 2 | 0·090 |

I have included Polaris, as though the parallax is less than $\frac{1}{10}$th of a second, it is the result of a large number of different determinations. "A Fellow of the Royal Astronomical Society" has given an excellent list of the elements of some double stars on page 122. Two or three figures have dropped out from that list in printing: these Mr. Arkwright may add with his pen. They are: 6 Eridani, $a$, 3·82″; $\alpha$ Centauri $i$, 79° 24; $\xi$ Boötis $i$, 36° 55′; $\lambda$ Ophiuchi $a$, 1·19″; $\zeta$ Herculis $\pi$, 209° 30′. The elements of 42 orbits have now been calculated, in 19 of which the period of revolution is under 100 years. I do not know exactly what your querist may mean by Anno Domini "0"; but the place of Spica Virginis for B.C. 4 was XIh. 42m. 17s.; 0° 9′. I know nothing about its supposed connection with the star of the Magi. The following are the ten stars having the greatest known proper motion:

| Star | Mag. | Amount (annual) | Direction |
|---|---|---|---|
| 1830 Groombridge | 7 | 7·053″ | 144° 59′ |
| Lacaille, 9352 | 7½ | 6·957 | 79 9 |
| Cord. Zone. XXIII., 1584 | 8½ | 6·206 | 66 46 |
| 61 Cygni (mean) | 5½ | 5·220 | 52 30 |
| Lalande, 21185 | 7½ | 4·748 | 186 34 |
| $\varepsilon$ Indi | 5½ | 4·598 | 122 12 |
| Lal. 21258 | 8¾ | 4·403 | 202 22 |
| $o^2$ Eridani | 4 | 4·012 | 212 45 |
| $\mu$ Cassiopeiæ | 5½ | 3·830 | 115 0 |
| $\alpha$ Centauri | 1 | 3·625 | 282 55 |

The nearest known companion to Procyon is the small star whose angle and distance, in 1882, was 323 6° : 45 4″. The close companions, supposed to have been seen by some of the Washington observers, are probably not real, and O. Struve's was shown by its discoverer to owe its existence to an illusion. The companion predicted by Bessel has yet to be discovered.—H. SADLER.

[56349.]—**Portland Cement Concrete.**—Is not the red concrete you mean, Lascelles patent? I do not know whether it is the colour that is the subject of the patent. Neither do I know what pigment that may be. Red ochre or "raddle" either, however, would go a very long way in colouring Portland cement, and could be bought cheaply where they are found. I don't know about ground clay bricks answering, but sandy bricks certainly would. I should think any dark yellow sand would become red if burnt. Yellow ochre becomes red ochre if heated nearly to redness. There is red—nearly red—sand to be had at Reigate (Redhill), Surrey. I answer this in case no one better qualified does so.—MURANO.

[56353.]—**Planetarium.**—Search Rees's "Cyclopædia," a work far too much despised. It may be bought complete for about £4. The orrery calculations—both Jovian and Tellurian—are very full indeed. For a Saturnian orrery, there are particulars of my own in the "E. M." some four years ago, I think.—ANTARES.

[56357.]—**Telephone Switch.**—To "PHONO."—Will you kindly be a little more explicit? What is the office of the automatic switch? Does it cut in a speaking, local, or through-line circuit? I know nothing of such a switch-box, with telephone hanging to it, in use on P.O. circuits. Will you say where you saw it—were you looking at a

Blake's transmitter?—and what do you want it for?—M. L. B.

[56346.]—**Sellers' Screw-Thread.**—"Nystrom," in his pocket-book, says, William Sellers makes the angle of his thread 60°, with flat top and bottom, and of the following proportions, which are recommended by a special committee appointed by the Franklin Institute of Philadelphia. For full information see *Journal* of the Institute, May, 1864, and January, 1865.

Formulæ. All Dimensions in inches:—

$D$ = outside diameter of screw.
$d$ = diameter of root of thread, or of hole in nut.
$p$ = pitch of screw.
$t$ = number of threads per inch.
$f$ = flat top and bottom.
$o$ = outside diameter of hexagon nut, or bolt-head.
$i$ = inside diameter of hexagon, or side of square nut or bolt-head.
$s$ = diagonal of square nut or bolt-head.
$h$ = height of rough or unfinished bolt-head.

The height of finished nut or bolt-head is made equal to the diameter, D, of the screw—

$$p = \frac{\sqrt{16 \times D + 10} - 2{\cdot}909}{16{\cdot}64} \quad (1) \qquad t = \frac{1}{p} \quad (2)$$

$$s = 1{\cdot}414 + i \quad (3) \qquad d = D - \frac{1{\cdot}299}{t} \quad (4)$$

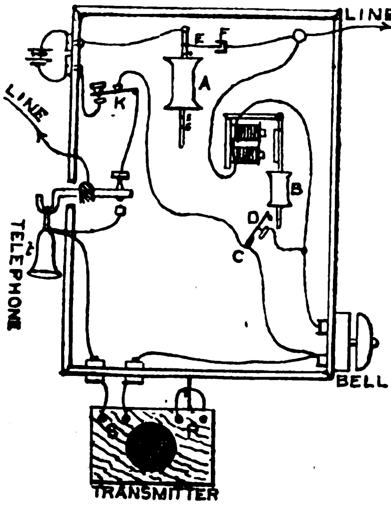
$$i = \frac{3 \times D}{2} + \tfrac{1}{8} \quad (5) \qquad o = 1{\cdot}155 \times i \quad (6)$$

$$f = \frac{p}{\ } \quad (7)$$

"Nystrom" also gives a table, with illustrations, of all the proportions, from ·25in. diameter to 6·00in. diameter. ·50in. diameter has 13 threads per inch, and 6·00in. has 2·25 threads per inch. I believe most practical men will agree that 12 threads to ·50in. diameter is too coarse for general purposes, and that 13 is far better. The table throughout is undoubtedly a modification of Whitworth's, and possibly a better one. Still, to Sir Joseph Whitworth the great credit is due, of rendering uniform and nearly universal that which was previously chaotic. Whitworth's system of screw-threads for bolts and nuts is now so firmly established that any attempt to vary would be futile.—Tubal-Kain.

[56358.]—**Chronic Cold in Head.**—Some years ago I fell into a state of health producing chronic throat and nasal catarrh, when, as a last resort, I took to Turkish baths, thanks to which, and to attention of action of the skin, I am now a quite different man. Let the querist have himself examined, and, if sound, give this a persevering trial. Locally the throat and nose may be treated daily with a gargle of sea water (easily made with Tidman's salt, say, 20 to 25 per cent. solution). For the throat use this cold, carrying the fluid well up behind soft palate; for the nose use tepid, sniffing it fearlessly out of the tumbler, held well up, and ejecting from mouth. I also call the querist's attention to what is being more and more advocated to preserve uniform warmth of the body and healthy skin action, viz., the wearing of woollen material only, avoiding linen and other vegetable fibre. On this see pamphlet published at 3, Princes-street, Oxford-street.—A. C. G.

[56361.]—**Telephone Circuit.**—I send a diagram of connections of Messrs. Brown and Saunders' individual telephone call apparatus, which, I think, is very simple. A is transmitter pendulum; B is receiving pendulum. If we fix the bob of the pendulum A at any point, it will vibrate a certain number of times in a certain time. Supposing it is set to the point marked 6, it will make the same number of vibrations as the receiving pendulum of No. 6 instrument would make in the same time. If at 5, the same number as receiving pendulum 5, &c. To call up.—The bob of pendulum A is set to the number required, key K closed, and pendulum set swinging; spring E makes an intermittent contact with F, sending intermittent currents to line. These currents pass through C and D, which short-circuit the bells, and through the receiving electro-magnet, and so on to earth. The pendulum whose time of vibration corresponds to the rate of the intermittent currents will swing, and no other pendulum on the line will move. As the receiving pendulum swings, it lifts up spring S, thus breaking contact with D, and causing the current to pass through the bell. The telephone is then lifted off the hook, and the line is open for conversation.—J. Broadbent.



[56363.]—**Pasteur's Vaccine for Splenic Fever.**—I beg to say that experiments with Pasteur's vaccine for splenic fever were undertaken at the instance of the British Government by Dr. Klein. The result was that the vaccines killed a number of the animals experimented on, and Dr. Klein concluded a report on the subject by stating, "This country is comparatively free from anthrax, and therefore the introduction and use of this so-called 'vaccine charbonneuse' seems to me most dangerous, and capable of producing incalculable mischief."—Benjn. Bryan, Secretary International Association for the Total Suppression of Vivisection. Offices: 1, Victoria-street, London, S.W.

[56365.]—**Flat Foot.**—"Pedestrian" requires a pair of boots made on lasts that are more arched in the waist than his feet are, with heels and stiffeners longer on the inside.—J. F.

[56365.]—**Flat Foot.**—First, a caution or two to a fellow sufferer. Don't pay a high price for any so-called arch-supporting boots: they simply force up the centre bones, and make a flat foot still worse. An eminent London surgeon advised me to have a strong plate of iron made into the waist. This should not be curved enough to force up the bones or be painful, but just sufficient for the arched portion of the foot to rest on. Have the boots made so that the whole of the foot stands on the sole, not a portion of it on the welt. Take particular care to leave room for the great toe to be in a straight line—not pushed toward the right on the right foot, and to the left on the left foot. The heels should not be more than ⅞in. high. They must be broad, and brought ¾in. further forward than usual. When being measured, stand on a piece of paper and let the bootmaker take an outline of the foot, leaving room for all the toes to touch the ground. The outside of the foot should be well supported. Boots so made are not ugly and clumsy-looking, and wear a long time. Thick soles do no harm. There is a valuable article on the cure of a bad case of flat foot in the *Medical Times and Gazette* of March or April, 1872. It is published at 11, New Burlington-street, London. Dr. Druitt says, "the affection depends on weakness of the muscles, especially of the *tibialis anticus* and *posticus*." He recommends that the inner edge of the heel should be thicker than the outer, and that the feet should be turned out very little in walking. He also advises that a boot with a high heel should be worn. I do not presume to differ from so eminent an authority. At one time a walk of a mile or two gave me pain. Now I can keep walking on London pavements for eight hours, and go to the top of many of the highest buildings during the time, and at the end of the day walk home without being foot-weary. I simply give my own experience as to the best cure, and hope it may be of use by saving pain to others. I adopted the flat, broad sole and low heel, but not the iron waist. Never lace boots very tight; muscles will remain weak if not exercised. R. W. J.

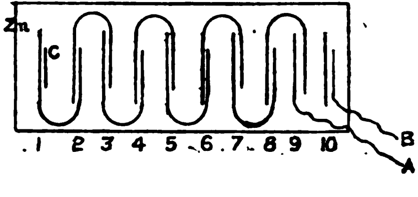
[56368.]—**Ventilator.**—If the querist will take off the elaborate top from the model referred to, and will blow at the tube, he will be surprised to find the cotton wool will be sucked up equally as well as when the top was on. A plain tube with cover to protect from rain will answer as well in most cases as fancy and expensive appliances. This was shown by experiments at Kew some years ago.—B. Boothroyd.

[56371.]—**Spoiled Negative.**—If "Sepa" moistens a piece of sponge or cotton wool with spirits of turpentine, and gently rubs over the negative, it will remove the stains easily; in fact, it will even remove gran. fog.—Photo. Publisher's Printer.

[56372.]—**Flowerpots.**—To "M. W. S."—My moulds are made of hard boxwood, attached to the lathe as a chuck, the inner mould forced along by means of the dead centre. I beg to thank "M. W. S." for his suggestion of plumbago; shall try it, and give results.—S. Arlidge.

[56379.]—**Bichromate Battery for Lighting.**—To Messrs. "Accumulator" and "Bobadil."—I am very thankful for the prompt and kind replies to my query; but I am a little perplexed to know why "Accumulator" urges the necessity of having liquid-proof separate cells (and I must say my reason dictates to me it should be so), whereas "Bobadil" appears to pass this question over as of no importance. I have now 10 earthenware jars in which I intend suspending the elements. "Accumulator" points out the necessity of having two carbons to one zinc; but does not state how much surface or solidity one should bear to the other. My zincs are $\frac{1}{10}$in. thick, 1½in. wide, and 5in. long. The carbons are $\frac{4}{10}$in. thick, 1$\frac{6}{10}$in. wide, by 6½in. long. I should wish to know whether the carbons, being larger than the zincs, are not sufficient without doubling their number; also, the quantity B. of P., and sulphuric acid and water required. After all it appears a doubtful experiment. —In the Dark.

[56379.]—**Bichromate Battery for Lighting.**—If I understand "In the Dark" aright, he has arranged and connected his battery as in the annexed diagram—A being the wire from the 9th zinc, and B the wire from the 10th carbon leading to the lamp; then what becomes of the first carbon and last zinc? Surely, "In the Dark" has not overlooked this. If this is as it should be, the total E.M.F. of the battery may be too low. A Swan lamp requires about 2·5 volts for each candle-power; a lamp of ten candle-power would, therefore, require 25 volts to work it, in addition to force required to overcome the resistance in wire, &c. Can "In the Dark" find the total E.M.F. of his battery?—he will then know if his power is enough. As a standard, I might mention that a quart Bunsen cell, with 12 parts of water to one of strong sulphuric acid in the outer cell, and strong nitric acid in the porous cell, yields an E.M.F. of 1·9 volt.—J. Kean, Northampton.



[56386.]—**Shuttles.**—Loom shuttles must be of wood tolerably heavy and very straight in grain, as they are cut away inside almost to a shell. They are tipped with steel at the points; but the friction is at the sides and bottom, where they are unprotected. The firm I am with runs about 2,000 quick calico looms, and the shuttles, some are boxwood and some ordinary teak, I think. The boxwood is best, as it wears well, and takes a fine polish with friction.—Cotton.

[56387.]—**Battery.**—This is not a battery; but only one cell. You do not say for what purpose you require to use it. Charge with a bichromate solution in the proportion of bichromate of potash, ¼lb.; sulphuric acid ¼lb., to one pint of water. You can dilute if too strong.—C. D. R.

[56389.]—**Incandescent Lamp.**—1. Electrical power is measured in watts (not volts), the product of the current in ampères by the difference of potentials in volts. 2. A comma should be inserted after "high" (third line from end), and the one after "numerically" omitted.—J. Rance.

[56391.]—**Haydon's Cutter Bar.**—I am much obliged for the replies to my query, which have greatly increased my interest in this particular cutter bar. There can be no doubt about my having a real Haydon cutter bar, because I bought it at the well-known Norwich lathe maker's. Will "J. K. P." kindly afford me the "more light" he offers. The reply of "O. J. L." is very instructive, and it is really very kind of him to take so much trouble. I should be grateful for answers to my query as to depths of cut this bar should stand under the conditions named. The shank of my cutter bar is $\frac{5}{16}$in. square, and the cutters are ¼in. square. It would be useful if the maker of this bar would make and sell a gauge, or set of gauges, for all the angles used on the cutters to facilitate correct grinding. As regards the method of grinding explained by "O. J. L.," would not the diameter of the grindstone affect the height of the grinding block and the resulting angles on the cutters? If so, some readjustment would be necessary as the stone wears.—Bellicose.

[56394.]—**Medical Battery.**—From the description, this is a Leclanché, and may have been in use several years. These small cells are very liable to get out of order in consequence of the creeping salts. If this is the case, you must clean all the connections and charge with a half-saturated solution of sal-ammoniac. If the current is still weak, the cells must be taken to pieces and fresh manganese and zincs put in.—C. D. R.

[56400.]—**Harmonium.**—You can get a full compass (5 octave) harmonium in a case 3ft. long, inside measurement, the length of a full compass keyboard (61 keys) being 33in. All the ordinary fittings can be used, saving you a great deal of trouble, making things specially, but if you only want thirty keys, your case should then be 18½in. between the cheeks: that allows you 16in. for your keyboard, and an inch and a quarter key-block each end. As regards making the reeds yourself, I should advise you not to try, as it requires great experience in making and voicing them equal, and you can get them easy and cheap.—W. H. Taplin.

[56400.]—**Harmonium.**—A compass of 30 notes is not sufficient. If the querist really wishes to make a harmonium, have, at least, four octaves, or 49 semitones. Your case being only 3ft. long, is barely large enough for 5 octaves, that is, if 3ft. is the outside measurement. A 5-octave keyboard takes up a space of 33in. in length, and a little additional space must be allowed for key-blocks, which are small pieces of wood placed at the end of each outer key. To look tidy, the space between each inside cheek should be at least 3ft. for a compass of 5 octaves. If a compass of 4 octaves is adopted, 32in. between cheeks will be quite sufficient space to allow. It is hardly worth while to make reeds, particularly as a set of 61 notes (5 octaves) can be bought for 6s. 6d., which are quite good enough for ordinary home practice. A good one-row pan can be purchased for 4s., and a passable keyboard for 12s. 6d. A person who asks, How can I tune reeds? can scarcely be considered competent to undertake the operation of tuning, and the method of flattening or sharpening the reeds has been explained more than once in the English Mechanic. "Ready made" reeds can be purchased from most musical instrument dealers; but if a few sets are required, it will be some advantage to purchase from the reed makers, who advertise in most of the musical publications. Let me advise the querist. 1st. Do not make a harmonium less than 5 octaves compass. 2nd. If you wish to economise, make all the parts that you think you can successfully accomplish, and buy all the remaining portions. 3rd. Discard the foolish idea of adopting so ridiculous a compass as 30 notes. Such a compass is not sufficient for general musical purposes with regard to keyboard instruments. 4th and last, but not least, Do not proceed further until you have acquired sufficient knowledge of the work you wish to undertake. This you can obtain from the pages of "Ours," and I am quite sure that no reasonable question with regard to the matter will remain unanswered.—G. Fryer.

[56392.]—**Cubic Feet of Air per Minute.**—

—Taking air as $\frac{1}{817}$th the weight of water, then—

$$\frac{v^2}{2g} = \frac{16\text{ft.}}{64}$$

(taking $g = 32{\cdot}5$ft.), then—

$$\frac{16{\cdot}25\text{ft.}}{65} = \frac{16\text{ft.}}{64} = 4{\cdot}0311\text{ft. per second.}$$

And air being $\frac{1}{817}$th the weight that water is, then it would require 817 × 4·0311ft. of air per sec. to maintain 3in. column of water = 3293·4087ft. The theory is that water falling from any given height would acquire a certain veloc., to be derived from the formula $\frac{v^2}{2g}$ = height named. And, therefore, if the reverse were to happen, a flow of water to be obtained by use of the same formula used in an inverse method, the height which a certain flow would maintain would be the result. If a certain flow of water maintains any ascertained head or column, then 817 times the flow of air would maintain the same head or column. 3,268ft. per sec. = ·59289 mile per sec.—G. Pinnington.

[56402.]—**Calculating Power Required.**—One would first require to learn the lengths of the lever from end to fulcrum, and from fulcrum to point of application.—G. P.

[56407.].—**Facing Stop-Valve.**—I should consider one of two causes is the reason why you are so troubled. The first is, that most probably there is a joint broken, by means of which steam escapes into the steam-chest. But another thing may, and would, cause the defect in question: did you alter the length of the starting-valve spindle? Because if you shortened it, the valve, when in the "shut" position, would still allow part of the port to be open, and through this the steam would easily keep the engine in motion. I have in practice had this occur. If you have faced the valve to its face by scraping, the leakage past should be very small indeed.—Invicta.

[56409.]—**Sulphur in Coal and Coke (Estimating).**—Powder 50 grains and put in a flask with 1oz. of concentrated nitric acid, apply heat cautiously until fumes cease, then add ½oz. more of nitric acid and boil as before, dilute result with 8oz. water and filter; add to the filtrate barium chloride in excess, collect, dry, and ignite precipitate; transfer to tube, heat with dilute HCl, recollect, wash, dry, ignite, and weigh—117 parts are equivalent to 16 parts sulphur.—B.Sc., Plymouth.

[56410.]—**Finance.**—"Sefton Park" would save £30 3s. 8d. per annum for 12 years by patching now and renewing in 6 years' time.—G. Pinnington.

[56410.]—**Finance.**—"Sefton Park" will save about four years' use of his machine by patching now. Take the position in both cases at the end of twelve years: 1, By renewing now, the total cost and interest is £1,120; 2, by patching now, and renewing in six years, patching £316; renewing £700; interest £304—total, £1,320. This exceeds the former by £200; but in the first case the machinery is done, and in the second there is presumably six years' work left.—B.Sc., Plymouth.

[56414.]—**Exhaust Pipe.**—The remedy I should apply if the exhaust be not absolutely required for forcing the draft, is to use one of two known makes of "silencing chambers." There are, in one case, an elongated box, filled with pebbles or an equivalent, so that the exhaust is checked, and passes away noiselessly. But this form, unfortunately, is dear, and produces a back pressure against the engine. The other is of a widely different construction, and is more like a circular box. No back pressure is caused by it, and I consider it superior in many respects. Both are patented. In a case where this latter apparatus was used in connection with the exhaust steam from a large beam engine which was before very noisy, the exhaust issues from the end of the pipe continuously and without noise. If our friend the querist likes to advertise his address, I will send him names and addresses of both the makers, and he can then deal with the matter with them direct, as I have no interest in the question of supply.—Invicta.

[56416.] — **Model Engines for Paddle-Boat.**—If you are contemplating a new pair of engines, and from your query on p. 178 I assume you propose to use paddles, the boat being, say, 6ft. long, the centre of the paddle-shaft should be 2ft. 9in. from the bow. Then, as to the class of engines, to save room lengthways, vertical trunks might be used; but they are not so well suited for models, because the trunk is a great source of friction, and also it is a cause of a great loss of heat on the top end stroke of cylinder. A pair of oscillators would take up, if anything, less room, and be more economical. Now if I was making such a pair of engines, I should place them diagonally, both piston rods working on to the one crank. This would mean taking up more instead of less space for the engines; but it is space well employed. The second crank is then saved, and the weights are all kept amidships. Now you might use for paddles a pair of oscillators, say, 2in. bore and 4in. stroke, with two such boilers as shown at p. 110; or you might use one such boiler, and a pair of smaller engines. The size I name will go into the boat either as verticals or diagonals. The engines should be slide-valve cylinders without eccentrics, and reverse easily as well by the movement of the one reversing lever. Crank shaft for the 2in. by 4in. cylinders should be ½in. diam. in the journals and shaft; paddle wheels 12in. diam., 5in. wide on the floats, each float being 2in. deep. Ample power also is available to work a feed pump to supply both boilers. I will be happy to give sizes for a pair of smaller engines for use with one boiler, or any additional information on any point you may desire, and I think through these pages we can put you in the way of making one of the most powerful and successful models yet afloat. At least *I* will try.—Invicta.

[56421.]—**Bichromate Cells with Hydrochloric Acid.**—I see no objection to the use of platinum instead of carbon with this solution. Probably the querist fears that platinum will be dissolved, but I do not think there is any risk of that. I do not see any advantage in the substitution however, except that platinum is more easily connected with than carbon is, and not so liable to fracture.—Sigma.

[56421.]—**Bichromate Cells with Hydrochloric Acid.**—There is no practical advantage in using platinum foil instead of carbon, let alone the cost of the former, and unless the platinum is of sufficient substance there is a positive disadvantage. The use of platinum-covered lead plates has been tried; but without any sufficient result to justify their use.—C. D. R.

[56429.]—**Mosses.**—To study these plants it is necessary to have "A Synopsis of the British Mosses," by C. P. Hobkirk (London: Reeve and Co., 1884). It is a little book, and not expensive. No plants can be easier to preserve; dry them between blotting paper under very moderate pressure, and fasten them to half-sheets of writing paper (commercial note is a convenient size). Some may be kept in small envelopes attached to the papers, the genera made up into bundles. A microscope is required to make out details of structure.—R. C. D.

[56441.]—**Sensitive Flame.**—A form of jet which I have made myself, and which in my hands succeeds well, is made as follows:—I take a piece of glass quill tube, draw it down to form a beak or jet, then cut off just above the contracted portion. Now anneal, and with a knife-edge file cut in the glass jet a V-shape. A very little does. The pressure of the gas which I use from a gas-bag under pressure has even then much to do with it. But I find the glass jets give the best result by far. They give the greatest motion, and are the most sensitive with me.—Invicta.

[56443.]—**Lathe Fly-Wheel.**—I have exactly the combination you name. The speed cone on the mandrel is made with grooves for round (or in any case V-shaped) belt. The fly-wheel is simply an ordinary shafting pulley of the right size; and I may add, it works most satisfactorily. It is, of course, not practicable to alter the speed by shifting to a smaller or larger cone on the mandrel cone pulley.—Invicta.

[56445.]—**Driving Sewing Machine.**—I should think you would most certainly find it hard work. You have neither weight enough in your fly-wheel, nor speed enough either, so that on every hand you are at a disadvantage. Your best remedy is a larger and much heavier fly-wheel; but even then the stand and parts are not suitable.—Invicta.

[56448.]—**Double Electric Bells.**—With line wire of the size named there should be no difficulty in ringing two bells well with a battery of three cells if all are in good order. As already explained in the "E. M." for Dec. 5th and Jan. 9th last, the current will in the first place elect to pass through the bell which offers least resistance, and during the interval when the circuit is broken there by the stroke of the hammer, it will pass through the other bell. The only adjustment needed is to set the bells so lightly that either will ring with one cell, or will strike instantly if a momentary contact is made through the whole circuit with two cells. You would then have ample margin with three cells to make both strike quickly enough to ring perfectly in the shorter space of time allowed to each when connected together in multiple arc. If your hammer springs are too strong to admit of such light adjustment without unduly shortening the stroke, an additional cell would probably overcome the extra tension. I have never found platinum contacts decompose by the action of the induced sparks in the manner described; even in large houses, where the batteries are usually six or eight cells, and some of the bells are large enough to give smart shocks to anyone through whom the induced current passes. But I have often met with bells presenting these appearances, and have on examination found them to be platinised with bits of German silver. In another case where platinum had been really used, it was coated with solder, which had run over it and had not been cleaned off after fixing. The contacts of the majority of French bells are made of silver, which seems to be practically as good for the purpose as platinum costing about six times as much.—R. T. Lewis.

[56450.]—**Regenerative Gas-Burners.**—I do not know the Wenham or Clark burners; but during the last few weeks I have been trying one of the Bower burners, and do not find that any shadow is cast directly under the lamp. I do not find that it heats the room more than four ordinary flat-flame burners did. It can be placed in direct communication with a ventilating tube. The light is white, perfectly steady, and gives over 6 candles per cubic foot of gas consumed. Mine burns 7½ft. per hour. I have one of Siemens' regenerative burners, but do not obtain very satisfactory results, the best regulators not supplying the quantity of gas with sufficient accuracy, and the large shadow which is cast under the burner is a very great objection. Can anyone give description of the Wenham or Clark burners?—Joseph Hall.

[56456.]—**Copper-Zinc Battery.**—The best thing the querist can do is to sell his copper plates for old metal, or, failing a market, give them away if he has no other use for them. They only waste acid and time. Let him replace them with plates of carbon, or, better still, with platinised silver. Bichromate of potash would be useless with copper plates, which are of use only in a solution of sulphate of copper in a porous jar, working as a Daniell cell. —Sigma.

[56456.]—**To Electrical Advisers.**—Get new jars and porous pots to match. Now charge as follows: In porous pots place copper and charge with sulphate of copper; fill the porous cells about three-quarters full, place zincs in outer jars, and fill both porous and jars up with water about 1in. from top; no need to use sulphuric acid. This way is best.—W. A. B.

[56456.]—**To Electrical Advisers.**—"Friar Bacon's" battery seems to be very soon polarised. He had better discard his copper plates in favour of carbon ones, which are cheap enough, and then use the ordinary bichromate solution. If he requires a powerful current for, say, an hour, let him use the battery without porous cells. If he is content to have a weaker, but more lasting current, let him use those articles to place his zincs in. The bichromate solution would destroy his copper plates. —B. Harcourt.

## UNANSWERED QUERIES.

*The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.*

## QUERIES.

[56460.]—**Observatory.**—I shall be obliged for some information in regard to the cylindrical-drum style of observatory. Should like to know whether it is as suitable as the hemispherical dome for a latitude where snow remains upon the ground for some time; also whether there is more danger of the drum being blown off than a dome? My observatory will go on top of the house, the telescope resting upon a chimney for a foundation. As the house will be heated by steam, and the chimney closed up, this will give a very good foundation. There is such an observatory figured in Crossley's and Gledhill's "Handbook of Double Stars," but very little description accompanies it, and I should like to know whether the sides of the drum are made of canvas, and how much pitch there should be to the roof, &c. My telescope is a 4in. equatoreal, by Cooke, with driving clock, &c., height from floor to centre of motion, about 6ft. 4in., focal length, 5ft. I thought of making the lower portion of observatory, about 10ft. square, and 5ft. high, and the drum about 9ft. diameter, and 4ft. high. Would this be the right dimensions? How does the slit in the roof work? Is there any danger of water coming down on the instruments when the slit is opened after a shower of rain?—ARLINGTON.

[56461.]—**Pressure on Sides of Tank.**—A very good and simple rule was given a short time back in the "E.M.," to find the pressure at base of any column of water, by the use of the constant 434. Would some kind friend give a simple or similar rule, to find the pressure on sides of a tank when filled with water?—J. B.

[56462.]—**Locomotive History.**—I should feel obliged if anyone could tell me what kind of valve gear was that of Messrs. J. and C. Carmichael, which was fitted to some locomotives about 1833; not being able to find it in any work on the steam engine, although it is sometimes alluded to. A diagram will not be necessary for explanation.—TELEGRAPHIST.

[56463.]—**Vertical Boiler.**—To "INVICTA."—I am making a horizontal engine with cylinder, 2in. bore, 3½in. stroke. Will you kindly help me by giving dimensions of a vertical boiler suitable for same, to make plenty of steam, and be perfectly safe?—T. H. WARD.

[56464.]—**Variable Resistance for use with Ammeter.**—In working with Ayrton and Perry's ammeter, there is considerable risk of putting the instrument out of adjustmennt, from the violent swing of the needle, if the circuit through a strong battery is abruptly closed. Can anyone suggest a simple form of apparatus by which one turn of a handle would give a resistance varying, say, from 100 ohms to nothing? I have thought of using two slender rods of gas carbon or pencil-lead, with a slider between them as in Poggendorff rheocord; but perhaps someone may know of a better arrangement.—E. R. P.

[56465.]—**Boiler Tubes.**—I want to retube a horizontal boiler with 38 2½in. tubes, 7ft. long. How far should they project in firebox and smokebox, and do they require any finishing except by the expander? Is there danger in expanding tubes too much? Should I get the tubes thicker than No. 11, B.W.G.? I have been accustomed to engineering work, but have never done anything at boiler-making, and cannot get a boiler-maker, except from a very great distance, so that any information on the above would greatly oblige.—B. P.

[56466.]—**Transit Instrument.**—I have a transit instrument, and in order to adjust it, have been endeavouring to determine time by the method of double altitudes, I should be much obliged if some one of your astronomical correspondents would inform me if the following data and calculations are right:—On p. 169 of Godfray's "Astronomy," the following formula is given for the correction to be applied for change of declination, when the sun is observed:—

$$x = \left(\frac{\tan.\ \phi}{\sin.\ t} - \frac{\cot.\ \triangle}{\tan.\ t}\right)\frac{t\ \theta}{15}$$

Where $\varphi$ = latitude = 54°3'56"
$\triangle$ = polar distance at apparent noon.
$\theta$ = small horary decrease of polar distance
T = mean of clock times.
$2t$ = elapsed time between observation.
$x$ = correction to be subtracted from T to give clock time of apparent noon.

On Oct., 3rd, 1884, observing the sun before and after noon, with a good sextant, the first contact of the real image of the sun, and that reflected in mercury, took place at 10 33 14, and the second contact at 1 27 20

$$\begin{aligned}
&\text{Hence } T = 12\text{h. } 0\text{m. } 45\text{sec.}\\
&t = 1\text{h. } 26.\ 49\tfrac{1}{2}\text{sec.} = 21^\circ\ 45'\ \text{nearly.}\\
&\theta = -\ 58.\\
&\triangle = 90 + \text{declination} = 90^\circ + 4^\circ\ 13'\ 27''\\
&\text{Cot. } (90^\circ + a) = -\ \text{tan. } a\\
&\text{log. tan. } \varphi = 10{\cdot}1398021\\
&\text{log. sin. } t \quad \underline{9{\cdot}5688555}\\
&\qquad\qquad 0{\cdot}5709466 = \text{log. } 3{\cdot}723\\
&\text{log. tan. } 4^\circ\ 13' = 8{\cdot}8676317\\
&\text{log. tan. } 21^\circ{\cdot}45' = \underline{9{\cdot}6009280}\\
&\qquad\qquad \bar{1}{\cdot}2667028 = \text{log. } 0{\cdot}1848\\
&t = -\ 87\\
&\qquad 3{\cdot}723\\
&\qquad \underline{0{\cdot}185}\\
&\qquad 3{\cdot}908\\
&\frac{3{\cdot}908 \times -\ 87}{15} = -\ 24\ 7 \text{ seconds.}
\end{aligned}$$

Hence 20·7 seconds is to be added to 12 0 45, giving 12 1 9.7, as the corrected time of apparent noon.—X. N. X.

[56467.]—**Notice to Quit.**—Could any subscriber oblige me by saying how to act in the following case: I have a person who rents a shop of me, as a monthly tenant; as I required the shop for my own use, I gave him a month's notice to quit, which expired on the 25th last, but he has not given up possession, neither has he paid the rent. Can anyone inform me how to get possession as quickly as possible, and with the least expense?—PERPLEXED.

[56468.]—**The Ochorowicz Telephone.**—Will any brother reader (or the Editor) oblige with a drawing of the above telephone? From the description given in issue of April 3rd, I really cannot make out what it is like. Perhaps someone with more intelligence has done so. I am sure this will be welcome to all telephonic readers, irrespective of—EXPERIMENTER.

[56469.]—**Skrivanoff's Dry Battery.**—To "BOBADIL."—You simply repeat "Starlight's" words of of page 119, Oct. 3rd, 84:—Boil for three hours in a glass dish, one part of oxide of mercury, and four parts of chloride of ammonia, &c. Now I think that both these substances are dry, therefore what liquid are we to boil them in, and how much of it? By so doing you may greatly oblige others as well as—EXPERIMENTER.

[56470.]—**Fitting Fusee Chain.**—I wish to fit a new chain to English bracket clock. Directions will oblige. I see nothing mentioned on this subject in last six volumes.—NOMEN.

[56471.]—**Legal.**—Having become surety by signing a promissory note, as I thought for the sum of £2, I am now summoned for the sum of £2 8s., balance of a promissory note for £4 10s., the sum of £2 2s. having been repaid. At the time of signing the promissory note, I signed my name, viz.:—"Thomas White agrees to be answerable for the sum of £2," but the money lender said it was not necessary to say that, and rubbed his hand across all but my name. Can any subscriber kindly inform me how to act. Shall I subpœna the borrower who saw me sign the promissory note?—ONE BEING IMPOSED UPON.

[56472.]—**Slide-Valve, &c.**—Will "Invicta," or any of our practical readers, please give size of slide-valve and throw of eccentric for small strong horizontal engine. I wish to cut off at quarter of stroke? Dimensions of ports:—depth, 1⅛in.; steam, $^3/_{16}$; exhaust, $^5/_{16}$in; bars, between, $^3/_{16}$in.; also say if ports are large enough, and what power it will give out with 80lb. pressure, and 800 revolutions per minute; diameter of cyl. $2^1/_{16}$in.; stroke 3¼in.?—GENERAL KOMAROFF.

[56473.]—**Corn Drill.**—Could any of our numerous readers assist me in the following difficulty?—Living in a district were there are a large quantity of allotments, we have some difficulty in getting our corn in rows, so that we can hoe it, and I should like to make a drill to take, say six rows, to be drawn by two men. Perhaps some of my fellow readers may have seen something of the kind, and would be able to help "One in a Fix." I have plenty of tools.—POSER.

[56474.]—**Training for Athletics.**—Could anyone give me any advice as to how to train for flat races, from 300yds. to one mile, which are to take place in about three weeks?—A. B. C.

[56475.]—**Nitrate of Iron.**—Will some of the readers kindly give me instructions how to make the best nitrate of iron, used by cotton dyers, and usually stands about 78 or 80 Twaddel, and is sold about 2½d. per lb. sometimes 2d., and I will give, in return, anything in my range in the chemical line?—H. H.

[56476.]—**Incandescent Lamps.**—Why is it that when an indcandescent lamp is glowing, if the glass of the lamp is broken, the influx of air into the vacuum causes the filament to be consumed almost immediately?—LIGHT.

[56477.]—**Chemical.**—Would some reader kindly inform me what is the reaction which takes place when estimating the amount of glucose by Fehling's solution? Perhaps Mr. Gray would assist me.—A. PRICE.

[56478.]—**Spectroscope.**—I have two well polished glass prisms 4in. long, and each side, 1½in. wide. Are these prisms long enough to be cut in two, to make four prisms for a spectroscope? Will any of your readers kindly inform me, and as to which is the safest way to cut them?—D. BOOTH.

[56479.]—**Surface Condenser.**—Kindly tell me if there is a rule stating how many gallons of water should pass though a surface condenser, per minute, per horse-power, and how many feet of cooling surface per horse-power in condenser?—SUBSCRIBER.

[56480.]—**Impure Iron.**—If a lot of galvanised iron and tinned iron tubing were melted down, would it make bad castings? I have always seen it so stated, but should like to know what would be the true matter with the iron.—MURANO.

[56481.]—**Diameter of Tube.**—Would some one kindly tell me, through your valuable paper, what would be the diameter of a tube made of sheet iron, about 16 W.G. in thickness, 14ft. long, to float a platform weighing about 6cwt., about 6in. or 7in. above the level of the water?—T. H. WALTON.

[56482.]—**Painting on Calico.**—I have several large calico advertising sheets to paint, but I find that capillary attraction causes the oil from the paint to spread out ⅛in. all round the letters, thus disfiguring the whole affair. Will someone tell me how to prevent this? A few hints from a practical sign painter, as to stretching and lining out large sheets of calico (say 20ft. by 12ft.) preparatory to lettering—also, the mixing of red, black and blue paint for same—would be esteemed a great favour by—AUSTRALIA.

[56483.]—**Linkwork for Slide-Valve.**—Would any reader kindly give me sketch and description of the linkwork for reversing and regulating the motion of the slide-valve in Webb's patent (L. and N.W.R.)? Can locomotives be reversed when in motion, or have they to stop before they can be reversed, for I often see the driver pull the reversing lever after engine has started—why is this?—LINKWORK.

[56484.]—**Varnished Wall-Paper.**—I have seen such paper, after having become dirty and smoky with time, restored again so as to make it look quite new. It was simply washed down with something I would like to know. Can any kind reader oblige by telling?—VIRAGO.

[56485.]—**Model Boat.**—I wish to build a model boat about 4ft. long. I intend to use the ready-cut wood used for window blinds. How broad should the boards be? How much should one board overlap the other? How are they to be fastened to the ribs and to each other? What kind of wood for ribs, and how many pairs of them should there be? An answer would greatly oblige—VIRAGO.

[56486.]—**Pressure.**—In using a hydraulic jack for compressing ensilage, can any correspondent inform me means to arrive at the amount of pressure applied at any time during the process? May add the jack I purpose using is up to six tons.—ROB. HARRIS.

[56487.]—**French Polishing.**—Will some kind readers of "Ours" give me instructions how to use French polish, and also to finish my work? I have tried many times, but I cannot succeed. I may mention that I require to polish chiefly old work; but any hints will greatly oblige—TURK.

[56488.]—**Zinc Battery.**—I am constructing some chloride of zinc batteries. Would they be much stronger if I used cylinders of zinc to go all round the porous cells instead of zinc rods?—E. A. WILLIAMS.

[56489.]—**Solar Eclipse.**—To MR. JOHN GRIGG.—Would Mr. Grigg kindly communicate full particulars, with diagrams, of his plan of photographing the sun by the aid of a 3in. telescope and ordinary plates? Was the photo. taken direct and enlarged afterwards? I feel sure that a full description would interest others besides—H. A.

[56490.]—**Wooden House.**—Will some reader kindly inform "C. G. P." if he knows of a builder of wooden houses; if they answer in this climate, and if he can see them in London or elsewhere erected and occupied?—C. G. P.

[56491.]—**Long-Distance Electro-Magnet.**—Will some practical friend kindly give me an idea how to make the above, as the ordinary electro-magnet is not strong enough for the purpose for which it is needed?—W. A. G.

[56492.]—**Jacket Pan.**—I want to work a jacket pan whose temperature in the inner pan shall range from 450deg. to 500deg. Fahr. The outer pan will be heated by a coke grate beneath it. I am anxious to learn what material is most suitable for use in the space between the two pans. I have thought chloride of calcium might answer, and also any substance (if not too expensive) driven off from tar by distillation at not below 500deg. Fahr. Will any reader be so good as to inform me whether either of the foregoing is suitable as a heat carrier from outer to inner pan, and also mention any materials that may be better adapted?—S. S.

[56493.]—**Waterproofing Tennis Racquet.**—Can any one tell me what to put on the gut of a tennis racquet to make it waterproof and last longer? I have had a racquet with black stringing which lasted tight and did not wear for years. What was put on the gut to make it so, and can it be done after the racquet is strung?—ARYAS.

[56494.]—**Soapstone Firebricks.**—On page 75, No. 965, Sept. 1883, of "Ours," it was stated that an American company had been formed for the manufacture of soapstone firebricks, for which it was claimed that they would not slag, and were superior in every way to ordinary fireclay. Can anyone oblige with any further information regarding soapstone bricks? I wish to know where the company's works are? The American Consul-General, in London, knows nothing of it. Perhaps some cousin of ours in the States does, and would oblige—MURANO.

[56495.]—**Feeding Bottle.**—Will one of your numerous readers kindly inform me how to prevent an ordinary feeding bottle from acting as a siphon, and thus causing the baby's clothes and bed to be wetted? This is a very small matter, but a very unpleasant one for persons troubled with it.—MORGAN THOMAS.

[56496.]—**Mineral Customs of Derbyshire.**—I should be glad if some one would inform me whether there is any treatise on the mineral customs of Derbyshire relative to the lead mining districts?—ANXIOUS.

[56497.]—**Sellers' Screw Thread.**—To T. L. REID, AND "ABEFES."—Will one of these correspondents kindly supplement the information given in their previous answers to this question, by explaining the principle upon which the formula for determining the relation existing between the diameter and pitch has been constructed? I should also like to know if this Americanism is supposed to possess any advantages over our ordinary Whitworth thread?—J. A. C.

[56498.]—**Linen Manufacture.**—Dr. B. W. Richardson states, on authority of Dr. Purdon, of Belfast, that in some linen factories if a girl under 18 gets a card she very rarely lives beyond 30 years, if she be constantly employed at her work, as she dies of consumption. Does this represent the facts of the case? What are the facts, as regards health, in the various departments of the linen manufacture? Can the evil effect of the dust be prevented by use of respirators? Are the high temperature and moist air injurious in practice where they exist? Does the same apply to all flax and hemp work, e.g., making of tow, canvas, thread, &c.? Will someone who knows kindly answer?—J. W. B.

[56499.]—**Electrical.**—Will you please rectify error committed in inserting my last query, two brushes being put instead of pushes? Please insert following: Will anyone tell me how I can fit two bells in one circuit, viz., one bell at each end, on one wire with two pushes one each end with battery at one end? I can do it with reversible pushes and battery at each end, but it is inconvenient? Please illustrate by diagram.—Crutesta.

[56500.]—**Gravity Leclanche.**—Mr. Preece, in his Cantor lectures, describes this battery, see Vol. XXX., "E.M." p. 160. He says, "The carbon plate is inserted in the usual mixture of crushed carbon and peroxide of manganese, passing through the zinc plate. Sal-ammoniac is placed on the zinc plate, and each cell is nearly filled with water." Can anyone give me a rough sketch of this zinc plate—it is evidently of special construction? The only weak point about the arrangement seems to me to be in the carbon passing through the zinc; of course there would be a large hole in the zinc plate so as to leave a good clear space all round, but then the battery would be short-circuited unless the carbon was well insulated. What is the best material to use for this purpose, and how far down should the insulation extend into the carbon mixture? Can anyone say from actual experience, if a cell, made as above, will last as long, and give a greater electro-motive force than one fitted with a porous cell, or is its only advantage in having the internal resistance reduced by doing away with the porous cell?—F.R.Met. Soc.

[56501.]—**Dynamo.**—*Re* letter No. 24107, of page 147, April 17. Will Mr. S. Bottone kindly answer the following queries relating to the above? Are the cogs and ring in one piece, and is the wire wound on the cogs or in the channels and thus enveloping the ring? What sort of iron (cast or wrought) are they made of? How are the sections of wire connected together, and to the commutator, and how many breaks are there in the commutator? What distance are the pole pieces apart when mounted? How would such a dynamo work if wound with No. 10 wire on field magnets and No. 12 on armature?—A. E. Slater.

[56502.]—**Faulty Dynamo.**—To Mr. Bottone.—I have put together one of Jones's 70 c.p. dynamos laminated armature, 10lb. 20 c.c. wire on magnets; 1¼lb. s.c. 20 on armature; at 2,000 revolutions it would not light two 10 c.p. lamps. I tried it in series—no better. I took off armature ¼lb. of wire, tried it again, with better results. I then took another ¼lb. off armature: it then lit up two 10 c.p. lamps properly. What was the matter that I could get no light at first? What should the resistance be between F.M.'s and armature, and how many revolutions a minute? Space for wire on F.M.'s 6 by 4; armature, 5 by 2⅜.—C. B.

[56503.]—**Motor.**—To Mr. Bottone.—By the current dividing, I mean that the armature and field-magnet were connected in parallel circuit, and this arrangement was not so good as the usual series. The former I used as a rough test only to see if the magnets were of equal power. Whether Bunsen or bichromate quart cell be used, the result is the same, viz., a good start lasting a minute or so, and then a gradual but constant slackening until almost total stoppage in five minutes, just as if the soft iron armature was polarised or its coil short-circuited.—Chingford.

[56504.]—**Hand Dynamo.**—To Mr. Bottone.—Will Mr. Bottone kindly say what sort of strap he uses for driving hand dynamos, also whether he runs it straight or across? I have made one of these machines, but find great difficulty in getting any strap to drive it. The difference between the driving and driven wheels is so great, that if the strap is run straight, only a very small part of pulley on armature is embraced by the strap; whilst, on the other hand, if run across, the wheels are so close together as to cause considerable friction at the crossing. Any information as to kind of strap used, also by what method it may best be joined, will be much esteemed by—Iota.

[56505.]—**Gas.**—To Mr. Fletcher or any of "our" Correspondents.—Will you be so kind as to tell me how to get the quantity of gas that will flow through a pipe ¼in. internal diameter at 1in. pressure, and if it would be twice as much at 2in. pressure, and so on? Hoping that some one will answer in plain figures, as I do not understand algebra.—Young Gas Man.

[56506.]—**Pattern Making.**—To "J. H."—I have got the numbers you advised me to get, and they contain the very thing I wanted, except the bracket for the half-nut for leading screw, and rack. If you would be so kind as to let me have a sketch how it is to be made, I will feel greatly obliged to you, and what number of teeth on each wheel of a train of 22 wheels, the first to have 20 teeth, as I have a lot of wheels that will do, it will only be a few I will require to get.—Busby.

**Restoring Spotty or Stained Negatives.**—This may often be satisfactorily done by converting the image into chloride, and redeveloping with oxalate developer. Belitzki dissolves one ounce of alum in a pint of water, and then adds to this 140 grains of bichromate of potassium and three fluid drachms of strong sulphuric acid. The negative is allowed to remain in this solution until it has become thoroughly yellow, after which it must be very thoroughly washed indeed. It is now exposed to a bright light for some minutes, and then immersed in the oxalate of iron developer until it is quite black. Now rinse, soak in a solution containing one part of citric acid to fifty of water, and finally wash. The point most to be noted is a thorough washing after the bichromate bath.—*Photographic News.*

# ANSWERS TO CORRESPONDENTS.

⁂ *All communications should be addressed to the* Editor *of the* English Mechanic, 332, *Strand, W.C.*

## HINTS TO CORRESPONDENTS.

**1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.**

**⁂ Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.**

## BACK NUMBERS.

We receive so many queries asking for directions how to make many instruments and appliances which have been fully described in back volumes that we have compiled a list, which we shall insert in this column at intervals, of those most frequently sent, and as the numbers are still in stock, new subscribers should consult the list before sending their questions.

Batteries: Nos. 741.
Bookbinding: Nos. 613.
Copying processes: Nos. 750, 753.
Electric machines: Nos. 628, 759, 840.
Electro-magnets: Nos. 756, 772.
Lacquers: No. 866.
Pattern Making: Nos, 938, 941, 943, 945, 948, 950, 952, 954, 955, 956, 958, 959, 962, 963, 965. 969, 973, 974, 978, 981, 986, 989, 993, 995, 998, 1,000, 1,001, 1,003 1,004, 1,008, 1,009, 1,010.
Silver-plating: No. 830.
Telephones: Nos. 695, 747, 865.
Varnishes: 478, 619, 675, 691, 723, 775.

**The following are the initials, &c., of letters to hand up to Wednesday evening, April 29, and unacknowledged elsewhere:—**

Smith and Coventry.—W. Saunders.—J. L. Gallard.—H. Milnes.—W. W. Breston.—D. Allingham.—J. J. B.—F. M. Rogers.—Anxious.—J. Kean.—J. C. Barter.—E. C.—E. B. F.—Legal.—Lantern.—An Amateur.—W. J. Abel.—Vandu.—G. R.—C. L. F.—W. L. Bevins.—Box Handle.—R. Forrest.—T. O. T.—W. H. Eavis.—Harmonica.—W. H. Elphick.—E. C. Oswald.—Verax.—A. R. James.—T. H. L.—Combustion.—L. N. W.—A Fellow of the Royal Astronomical Society.—Tubal Kain.—Invicta.—S. R. Bottone.—Rev. J. L. Pearson.

Sufferer. (All that can be said is that the food should be easily digested. It will have no effect on the paralysis.)—Indigestion Pills. (Better leave them alone.)—Otter. (If you will give some reference by which we may find the statement we may be able to help you; but why not apply direct to Sir W. Thomson.)—Brumbo. (If you wish to acquire a sound knowledge of electricity, procure Mr. Sprague's work on "Electricity: its Theory, Sources, and Applications" (E. and F. N. Spon, Charing-cross). For textbooks, get Prof. Guthrie's "Electricity and Magnetism," or Prof. S. P. Thompson's "Elementary Lessons in Electricity and Magnetism" (Macmillan).—T. K. (Look through recent volumes for information about electric lighting at home. The Bunsen cells will be useful for the purpose—not the Daniells; but a little experience will send you back to gas or paraffin oil.)—P. T. (See previous answer. If the engine is only up to one horse-power, it will not light twelve 20 candle-power lamps.)—T. (See the list of Back Numbers above.)—Volunteer. (It is a petroleum or mineral oil, and of course smells like it.)—English Mechanic. (We know of nothing better than bathing in hot water, and rubbing over with alum solution. See a number of replies in Vol. XXXVII., pp. 369, 415, 440, 462, 510, 557.)—Samuel Barbour. (Surely you know that the suggestion has been put in force by Mr. Webb, the locomotive superintendent of the London and North-Western Railway. See p. 581, Vol. XXXIV., and the indices of the volumes subsequently published. The question as to the balance of advantages has not yet been definitely settled.)—Diana. (Caused by small bubbles of air. 2. We do not know of any new law. You are not permitted to make and sell patented inventions. 3. See the indices.)—Turco. (What you ask for was given so recently as p. 548, last volume. You must use discretion as to the time; but the cold sponging or spray is certainly advisable, if not absolutely necessary.)—Delta. (We have said many times that indiarubber stamps cannot be made without apparatus, and that it does not pay to buy that apparatus unless the manufacture is to be carried on commercially. Directions will be found in back volumes.)—Miner. (You will find the weight per cubic foot of metals, &c, in any of the pocket-books—*e g.*, Molesworth's. There is no rule.)—Fred Williams. (Not that we know of.)—J. K. Smythies. (We have not seen it, so far as we remember; but at any rate it could interest a few only, and they would probably prefer to wait until the paper is published in full in the *Transactions* of the Institution of Civil Engineers.)—A. G. O. S. (An electrical belt is utterly useless as a remedy for anything of the kind; but you will find directions for making one in back volumes. The use of whole-meal bread, or the taking of a glass of cold water first thing in the morning, is far more effective.)—C. Simpkins. (We do not believe there is such a book published; but there are some works of the kind. In most textbooks tables of the kind are given. You should procure the catalogues of the publishers—J. and A. Churchill, and Macmillan, for instance.)—R. J. Urquhart. (The following method of varnishing silk balloons appears on p. 247, No. 895. Wash out the oil with methylated spirit and turpentine and then varnish with 4oz. benzoline, 1oz. boiled oil, ¼oz. indiarubber. Three coats, as thin as possible, and it takes some time to dry. Other recipes will be found in back volumes.)—Alfa. (Acetic acid, nitric acid, and other chemicals are used. See pp. 195, 227, last volume.)—Tooth. (If there had been an English address we should have given it. The price is one dollar, and we suppose you will have to write to Boston for the book.)—J. C. (Celluloid is the best substitute for ivory in organ keys.)—Camera. (Search the indices of even recent back volumes, and you will not say again that there has been little about photography. You do not say what kind of camera you use, though you are very explicit about distances and exposure. Suppose you procure one of the cheap handbooks of the art, and learn the rudiments. You will then be able to put definite queries which it will be possible to answer.)—Steel Cutter. (That is the only way to soften. Try again, covering the fire thickly so as to keep the heat as long as possible.)—Stud Wheel. (See indices. There are several books of the kind, which you will find in the booksellers' lists; but we cannot say which is simple enough.)—Young Engineer. (We do not know of a work on repairing the steam-engine.)—Verax. (An advertisement in the Wanted Column would no doubt bring you a list of the principal shipbuilding firms.)—E. H. (Procure a rod of carbon and pack it in a porous jar with equal parts of crushed coke and needle manganese. Stand the porous jar in an outer vessel containing a solution of sal-ammoniac and a zinc rod. Unless you intend to make up a number of cells, it is cheaper to buy one ready fitted. To make a battery, see p. 147, No. 1049.)—Script. (Do you not see that any ink capable of withstanding that test would be sure to be patented?)—Mascheba. (Probably a vegetable wax, but you ought to be able to ascertain all about it in your city.)—S. Barnett. (No one can say without examining the antique.)—W. M. (We believe the best plan is to add "finings," and allow the matter to settle in vats; but you might try filtering through ordinary filtering paper or animal charcoal.)—Cotton. (Hydrogen and oxygen. No. See the article on superheated water and boiler explosions in No. 1032.)—D. Booth. Not a "Fixed Star," was it? We give only occultations and near approaches of fixed stars.)—Veto. (A medical man must see the case; the sooner the better, if it is ulcerated mucous membrane.)—J. B. C. Breckenfeld, San Francisco. (Thanks, we shall be glad to receive them regularly.)—Elec. Lamp. (The Bunsen, but the fumes are decidedly objectionable; hence, most experimenters use bichromate. See recent back numbers. The Daniell cell ought to work as arranged, according to your description; but it is usual to make it up in the reverse way, using the copper in the outer cell, or copper cans, and the zinc in the porous cell.)—J. W. B. (The climate of Kent would, undoubtedly, be better for you. Why not try and obtain work at the Arsenal at Woolwich.)—One Anxious to Know. (Yes; the assistance of a solicitor is not absolutely necessary, but it is desirable.)—Devoniensis. (We cannot spare more space for the first matter; queries next week.)

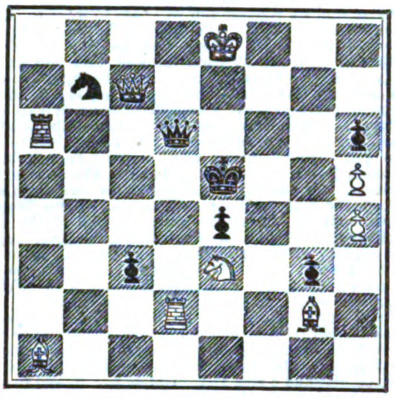
**Liquid Films.**—In a lecture recently delivered by Prof. A. W. Rücker at the Royal Institution, he said that the generally-accepted hypothesis of the nature of liquids was that they consisted of molecules held together by forces; the molecules at the surface of the liquid had these forces acting upon them from below only, instead of in all directions, so were in a different condition to those in the body of the liquid; what might be called surface films were consequently formed. A two-per-cent. solution of saponine, for instance, has a surface film which strongly resists the rotation of a needle when attracted by an adjacent magnet; but let the needle be placed less than a quarter of an inch below the surface: it will turn readily in the solution when the magnet is brought near. In a bubble of soap, or of saponine, the inner and outer strong surface films are very close together. To get durable liquid films, to keep sensibly in the same condition during experiments, the temperature must be even; this is effected by surrounding with water the glass case in which they are blown. To prevent evaporation the inside of the case must well be drenched with the liquid used for the bubbles. For the purpose of his experiments the bubbles were drawn out upon a ring of platinum above and below, so as to form a film-cylinder, which exhibited interference colours as the film thinned. In time the films became too thin at the upper part to show interference colours at all; at such parts they appeared black. As no colours then existed to afford means of measuring the thickness of the films the method was adopted of getting at it by measuring the amount of electrical current they would transmit; for this purpose two wetted gold needles were pushed into the back part of each film and the current transmitted by the part of the film between them was measured by means of a quadrant electrometer and set of resistance coils. By this means it was discovered that the coloured part of the film does not gradually thin into the black part, but that there is a hard and fast line between them; with solutions of some substances the coloured part is sixty-five times thicker than the black part. As certain technical objections could be raised to the electrical method of measurement, the plan was also adopted of putting a number of parallel black films in glass tubes; then sending a beam of light through all of them at once, and measuring their thickness by means of certain interference phenomena produced.

## CHESS.

All Communications for this department must be addressed to J. Pierce, Langley House, Dorking.

PROBLEM DCCCCXXXVII.—By "Væ Victis."

*Black.*



*White.* [9+7

White to play and mate in two moves.

Solution to 935.

| *White.* | *Black.* |
|---|---|
| 1. Q-K R sq | 1. Anything |
| 2. Q, Kt or B mates accordingly. (Six variations). | |

### NOTICES TO CORRESPONDENTS.

Correct solutions to 935 by E. S., Cheshunt (but variations not given), Brum (ditto), S. L. Chivers (ditto), W. T. Bayne (ditto), J. E. Piper (not very difficult), A. A. E. Lecluse (this little problem rather pleasing: K-Kt 6 is a strong move but Black has just one defence), V. S. Pochin (solution too palpable), Streetgate (somewhat easy for a tourney problem), R. F. Sunderland, (very easy), A. W. Orr, F. A. Vincent, Rev. W. Anderson (Old Romney), R. A. Bennett, Raymond, J. A. M. (very good), G. J. Slater (I fail to see any particular merit in this two-er), A. S. Olver, S.M. Cox.

To 934 by Raymond, J. E. Piper (very ingenious: a capital problem), A. S. Olver, Streetgate, A. A. E. Lecluse, A. W. Orr (very good), Brum, F. A. Vincent, Bronti.

To 933 by G. Stingfellow, C. Brady, J. Rayner, F. B. Webb, T. L. Robins, and J. Easton.

To 936 by J. E. Piper.

G. J. S.—You have overlooked in 934 1. B-Q B 2; you are right as to the answer if 1. B-Kt 6. Game received with thanks from F. A. Vincent.

**Separation and Determination of Methylic Alcohol in Presence of Ethylic Alcohol.**—C. De Poncy's process is based on the fact that methyl oxalate dissolves readily in water, whilst ethyl oxalate is sparingly soluble, and both oxalate form with ammonia amides perfectly insoluble in water. In 10cc. of the alcohol in question there are dissolved 10·8grm. oxalic acid, and the solution is saturated with hydrochloric acid gas. After standing for twenty-four hours in a well-stoppered bottle, 2cc. of the solution are mixed with 10cc. of water, shaken up and filtered. As methyl oxalate is completely soluble in water, there is obtained, on adding ammonia, more amide than if any equal quantity of pure ethylic alcohol had been employed. By a number of experiments we may ascertain the quantity of oxamide formed in the washing waters of the ethylic oxalates. For absolute alcohol the mean is 6·6. For methyl oxalate the mean is from 14·65, and 15 per cent. on the quantity of the methylic alcohol. If a mixture of methylic and ethylic alcohols is etherified, shaken up with water, and the filtrate mixed with ammonia to precipitate the amides, the proportion of methylic alcohol may be calculated from the quantity of oxamide obtained. For every one per cent. of methylic alcohol we obtain from 0·14 to 0·15 more than 6·6 per cent.—*Chemical News.*

**Every Workman connected with the Building** Trades requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence, at 332, Strand, London, W.C.

"THE BUILDING NEWS" is the Principal Journal representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is On Shilling for Twenty-four Words, and Sixpence for every Eight Words after

## TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve Months, Post-free to anypart of the United Kingdom. For the United States, 13s., or 3 dols. 25c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.

Messrs. James W. Queen and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 25c. gold, or Thirteen Shillings per annum, post-free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.

Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX. bound in cloth, 7s. each. Post free, 7s. 9d.
Vol. XL. now ready, price 7s. Post free 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or $2\frac{1}{2}$d. each, post-free from the office (except index numbers, which are 3d. each, or post-free $3\frac{1}{2}$d.)

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free $2\frac{1}{2}$d. each. Indexes to Vol. XI. and to subsequent vols., 3d. each, or post free, $3\frac{1}{2}$d. Cases for binding, 1s. 6d. each.

## CHARGES FOR ADVERTISING.

| | s. | d. |
|---|---|---|
| Thirty Words | 2 | 6 |
| Every additional eight words | 0 | 6 |

Front Page Advertisements Five Shillings for the first 40 words, afterwards 9d. per line. Paragraph Advertisements One Shilling per line. No front page or paragraph advertisement inserted for less than Five Shillings. Reduced terms for series of more than ; insertions may be ascertained on application to the Publisher.

ADVERTISEMENTS in EXCHANGE COLUMN—for

| | s. | d. |
|---|---|---|
| Twenty-four words | 0 | 3 |
| For every succeeding Eight words | 0 | 3 |

ADVERTISEMENTS in the SIXPENNY SALE COLUMN.

| | s. | d. |
|---|---|---|
| Sixteen words | 0 | 6 |
| For every succeeding Eight Words | 0 | 6 |

⁂ It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions; and in cases where the amount sent exceeds One Shilling, the publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O's.

The address is included as part of the advertisement, and charged for.

Advertisements *must* reach the office by 1 p.m. on Wednesday to insure insertion in the following Friday's number.

## NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a Pink Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

**Epps's Cocoa.**—Grateful and Comforting:—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—*Civil Service Gazette.*—Made simply with boiling water or milk, Sold only in packets, labelled—"JAMES EPPS and CO., Homœopathic Chemists London."—Also makers of Epps's Chocolate Essence

**Holloway's Ointment and Pills.** — Coughs Influenza.—The soothing properties of these medicaments render them well worthy of trial in all such diseases. In common colds and influenza the Pills taken internally and the Ointment rubbed externally are exceedingly efficacious. When influenza is epidemic this treatment is easiest, safest, and surest.—[Advt.]

## OUR EXCHANGE COLUMN.

*The charge for Exchange Notices is 3d. for the first 24 words and 3d. for every succeeding 8 words.*

**Good Value Offered** (cash or instruments) for all kinds of sound or repairable Scientific Appliances.—Caplatzi, Science Depot, Chenies-street, near British Museum. Established 1862.

Wanted, a good Collection of **Stamps**, also coins and Bric a Brac of every description, good exchange, approval required.—Address, Edward W. Drury, Hull.

"**English Mechanic**, from commencement, 40 Vols., 19 bound, all in perfect order. No reasonable offer refused, owner going abroad. Will exchange for central-fire gun.—Major Allen, Gosport, Hants.

Small Balance **Timepiece**, bronze and silvered dial, mahogany stand, glass shade. Exchange. Electric Bell and Battery wanted.—H. Leeson, Coleshill, Birmingham.

"**Engineer**," and "**English Mechanic**," volumes of, up to present date.—W. L., 61, Regency-street, Westminster, S.W.

**Nickel-plating Vat**, 9 gallons, 6 Bunsen half-gallon cells, six nickel anodes; weight, about 7lb.; 14lb. Salts of Nickel, book of instruction, scratch brush, &c., cost £8 10s.—Offers, J. Grime, Hull.

**Hot-Air Engine**, Buckett's Caloric, half h.-p., quite new, cost £62 10s. Will take exchange. Want tools or anything useful.—J. Grime, Hull.

**Tricycles**, with Dunn's patent improved power appliance, 50 per cent. increase of power. Machines bought sold, or exchanged.—222a, City-road, London, E.C.

Good **Cooking Stove**, 2 feet 9 inch by 1 foot 9 inch. Exchange for good 6in. Slide-rest, or 50in. Bicycle.—A. Hutchinson, 41, Katherine-street, North Darlington.

**Bunsen Battery**, 10 cell, 5in. carbons, $4\frac{1}{2}$in. zinc cylinders, massive clamps, complete, in thorough order. What offers to G. Heys Jones, 12, Addison-gardens, Kensington, W.

Double (walnut) **Dark Slide**, quarter-plate, nearly new. Also some Locomotive Photographs. What offers?—W. Algar, Stonard-road, Winchmore Hill, London, N.

Wanted, small **Launch Hull**, Engine, Boiler, Propeller, together or separately; also 50in. Bicycle. Exchange Double Breech-loader, Lathe, &c.—T. Carey, Foynes, Limerick.

"**Electric Lighting**," by Sawyer; "Electric Lighting," by Du Moncel; "Practical Electric Lighting," by Hedges. All half-price, or exchange for Incandescent Lamps, Saloon Pistol, or offers.—E. Rose, Regent House, Sydenham.

**Table Engine**, 4in. stroke, six turned pillars, double crank, two connecting rods, weight 35lb., mahogany stand. Exchange.—Edwin Roebuck, Stoke, Staffordshire.

Horizontal **Copper Boiler**, riveted, 15in. by 7in., manhole, steam tap, lever safety valve, gauge cocks, water gauge with 3 taps, large iron furnace and stand, about 20 firebars, funnel. Weight 35lb. Exchange.—Edwin Roebuck, Stoke, Staffordshire.

Ten-Guinea **Diamond Ring**, new, in exchange for 2ft. Locomotive with link motion. No matter if damaged. Send particulars.—W. Haughton, 138, Park-road, Liverpool.

Vols. XXXI., XXXII., and XXXIII. "**English Mechanic**"; "The Metal World," complete in 3, and "Metal," complete in 2 vols. What offers? Would exchange good Banjo. —Stemson, 4, Grove-terrace, West Kensington.

**Martini-Henry Rifle**, quite new, with cartridge and appurtenances, cost £10. Exchange for Alexandre Harmonium, Organ, or Swift's Student's Microscope.—George Elliott, New Ross.

Wanted, an **Air Engine**, in exchange for **Horizontal** Steam Engine, in very good condition, cost 25s.—H. Wilson, Rock House, Clapham-common.

"**Races of Mankind**" (Cassell's), four Vols. in two, half-calf, handsome. Exchange for Berkley's "Mosses," or Braithwaite's "Moss Flora."—Fred. Brown, Post Office, Coggeshall.

Wanted, **Lathe**, foot power, small, with rests, suitable for watchmaker; must be cheap; good exchange offered.—Hunt, Watchmaker, 88, Widnes-road, Widnes.

What offers for 22 **Books** on Military and Naval Operations, 72 numbers English Mechanic?—Address, G. W., 21, Wellington-street, Bedford.

**Violin and Bow**, in case, complete; also Concertina Patent Lever Watch, &c. What offers?—193, King Edward's-road, Birmingham.

Half-Plate **Camera and Lens**, also $\frac{1}{4}$-plate Ditto, bath and printing frame. What offers?—M. Allison, Howwood, Paisley.

Will exchange a quantity of small **Screw Plates** for anything useful. Offers requested.—Robert Gough, 19, Haggar-street, Blakenhall, Wolverhampton.

"**English Mechanic**," 44 numbers, not very dirty, unbound, for 1870. Exchange.—S. A. Clark, Croft-street, Heckmondwike, Yorks.

**Galvanic Battery**, by Halse, in perfect order, cost £10. Will exchange for 50in. Bicycle or Facile.—C. F., 19, Merrow-street, Walworth-road, S.E.

**Telescope**, $2\frac{1}{2}$in. Reflector, two Astronomical Eyepieces, fine adjustment screw, on tripod stand, in oak case. What offers?—Joe Blain, Albert-square, Carlisle.

**Medical Coil and Bichromate Battery**, in mahogany box, good condition; for Electric Scarf Pin.—Joe Blain, Albert-square, Carlisle.

**Electric Railway**, with Motor and Battery, not quite in working order; can be made right by any amateur electrician. What offers?—Joe Blain, Albert-square, Carlisle.

**Sprengel Pump**, with latest improvements, five fall tubes, and arrangement for removing air from mercury, on board, ready for fixing to wall, suitable for exhausting high vacua tubes, incandescent lamps, &c., and by which a vacuum to 1,000,000 of an atmosphere can be obtained. Exchange for Microscope, or Sale, £4 10s.—H. Newbold, 25, Calthorpe-street, W.C.

Wanted, Hall's **Type Writer**, in exchange for small Dynamo, Microscope, Telescope, Half-plate Camera, Pocket Aneroid, Medical Coil.—W. Banks.

Wanted, 8 and 10in. Sliding, Surfacing, and **Screw** Cutting Lathes, must be good quality; in exchange for a One Horse-power Otto Silent Gas Engine, new last September.—W. Banks.

What offers in exchange (or cash) for 3 Siemens **Telegraph** Instruments, 1 Government Sextant, 37ft. 4in. Belting, 1 cwt. No. 15 D. C. C. Paraffined Wire, 2 doz. Leclanche Batteries. Can be seen from 10 to 8.—H. Beer, 23, Westbourne-park-crescent, Paddington, W.

Good 6in. centre **Lathe**, double crank-shaft, counterbalanced heavy flywheel, slide-rest, hand-rest, three T rests, grindstone, and spindle, lots of tools, drivers, &c. Will exchange for Knitting Machine, Bicycle, or anything useful.—W. J. Powell, Abertillery, Newport, Mon.

**Knitting Machine**, almost new, with ribber, cost £8 10s., 80-needle Cylinder, for Sale, or exchange for Ladies' Wearing Apparel. No rubbish.—Jane Bell, Metallurgist, Bexley Heath.

Offered.—Pocket **Telescope**, with extra eyepiece, and Microscope, with achromatic triplet. Wanted, good French-English and German-English Dictionaries.—Buffham, Connaught-road, Walthamstow.

Warranted Crucible **Cast Steel**, 7-16 to $\frac{3}{8}$ diameter, 2 to 3ft. bars. Exchange for anything useful. No reasonable offer refused for 1 to 10 cwt.—Gilbert, Oxford-road, Sheffield.

**Photo. Apparatus**, consisting of $\frac{1}{4}$-plate lens and cameras, tripods, $\frac{1}{2}$-plate lens, one by Voightlander.—Day, 56, Driffield-road, Old Ford, London.

**Micro. Photo. Objectives**, by Dallmeyer; also large dishes, baths, plate boxes, pressure frames, Stanley's $\frac{1}{2}$-plate set.—Day, 56, Driffield-road, Old Ford.

**Speculum**, Silver-on-glass, good definition, 9 inches diameter, 6ft. $2\frac{1}{2}$in. focus.—Day, 56, Driffield-road, Old Ford, London.

**Sewing Machine**, Clegg and Blacklock, for back Vols. of "E.M.," bound, or 5in. slide-rest.—Day, 56, Driffield-road, Old Ford, London.

Wanted, a pair of **Circular Bellows**, about 28in., lath or fan.—J. Reside, Brighouse.

Pair of Engineer's **Tap Wrenches**, set of Lathe Carriers, spanners, yacht's compass, with transparent card, steam injector, pair powerful magnets. Offers? — Alfred Crofts, Dover.

Splendid **Model Engine**, copper boiler, with all fittings; capital printing press, for bill heads, circulars, &c.; 100 candle-power Gramme castings. Offers.—Alfred Crofts, Dover.

**Lathe**, 7in. centre, suit woodturner, also back-geared lathe heads, 7in. centre. What offer?—A. G., 16, Lesbourne-road, Reigate.

"**English Mechanic**," about 100 numbers the last two years, clean. What offer?—A. G., 16, Lesbourne-road, Reigate.

**Lathe Heads**, 4½ to 6in. centres, T and slide rests, wanted in exchange for corresponding value.—Linscott, Ramsgate.

**Photo Glass**, 7 by 5, 5 by 4, 4 by 3, 18 dozen; 8 pints silver solution, quality guaranteed. What offers?—Address above.

Five quart **Bichromates**, zincs 6 by 3. Exchange Lancaster's ¼-plate "Le Merveilleux." Conjuring Tricks. Offers. —Prof. James, 33, Pride-hill, Shrewsbury.

A few good **Conjuring Tricks** for exchange, would make a first-class entertainment at a moderate cost.—Prof. James, as above.

**Bicycles, Bicycles**.—The Dreadnought Bicycle, with hollow forks both wheels, Æolus bearings, dropped handles, Humber scroll spring, enamelled plain black; and you can have your old machine allowed for as part exchange.—Rodgers, Bermondsey-street, S.E.

**Bicycle Springs**, one dozen for exchange.—Rodgers.

**Bicycles and Tricycles**.—Offers wanted for a few, together or separately. Several are to be exchanged.—Rodgers, as above.

**Press Screw**, 3in. diameter, 14in. long, 2 threads, Quantity of American Drills. Exchange offers.—152, Bermondsey-street.

Model Vertical **Engine and Boiler**, 1½in. bore, would work sewing machine. Exchange offers.—H. R., 127, Abbey-street, Bermondsey.

---

## THE SIXPENNY SALE COLUMN.

*Advertisements are inserted in this column at the rate of 6d. for the first 16 words, and 6d. for every succeeding 8 words.*

**Plating**. — Every description of Gilding, Silver Plating, Oxidising, and Bronzing, executed with very best finish. Speciality in nickel-plating. Special quotations on application. Send one stamp for price list. Small jobs attended to per return post.—Morris Cohen, 132, Kirkgate, Leeds.

**Fretwork**.—Illustrated Catalogue of every requisite and 400 miniature designs, 4 stamps.—Harger Bros., Settle, Yorks.

**Trouser Lengths**, 5s. each. Cheap Cloth for Ladies' Dresses, Mantles, Boys' Suits.—Hewitt, 37, Winfield Mount, Leeds. Patterns free.

**Electric Depot**, 10, Deansgate, Manchester.—Electric Breast Pins, 25s. Electric Bells, 4s. Induction Coils, 8s.—Millar, Proprietor.

Write for Hindle's **List** of Electrical Apparatus, free; all parts for amateur construction.—Irwell Vale, Helmshore.

A few Gramme **Dynamos** for sale, cheap.—WALKER and Olliver, 195, Severn-road, Cardiff.

**Electro-Motors** from 25s. No dead point. Battery equal Bunsen's. No fumes.—Walker and Olliver.

Leclanche **Cells**, Manganese, Sal-ammoniac, Bichromate, Bells, Wire, Pushes. Wholesale and retail.—Walker and Olliver.

**Dynamos** repaired or rewound. Advice given. Competent men sent to all parts.—Walker and Olliver.

**Microscopic**.—Good miscellaneous Slides for disposal, only 2s. 3d. dozen, post free.—Mathies, 42, McKinlay-street, Glasgow.

Shunt wound **Dynamo** and Serrin Arc Lamp, cost over £40. Will take £35 or good exchange.—John Grime, Hull.

Fletcher's **Foot Blower**, cost 35s., quite new; also large Blow Pipe and Hearth. Will take £2 10s., or offers.—J. Grime, Hull.

**Billiards**.—Great success of Thorpe's Patent Automatic Cue Tips. Cannot fly off. Cues retipped instantly.

**Billiards**.—Excellent testimonials from Roberts, jun. champion, and other professionals. £5 per week easily earned.

**Billiards**.—District Agents wanted. Send 9 stamps for particulars and sample cue end fitted with patent.

**Billiards**.—Five Shillings for sample cue, also fitted, and 3 extra tips. Thousands already in use.

**Billiards**.—Apply to sole representative for United Kingdom.—A. W. Morgan, Lancaster Avenue, Fennel-street, Manchester.

Hard **Vulcanised Fibre** for Magnet Heads.—Mosses and Mitchell, 68a, Chiswell-street, London, E.C.

Hard **Vulcanised Fibre** for all kinds of insulation. —Mosses and Mitchell, 68a, Chiswell-street, London, E.C.

Hard **Vulcanised Fibre** for carrier dry back plates. —Mosses and Mitchell, 68a, Chiswell-street, London, E.C.

Tudsbury and Sons' "High Tension" **Wimshurst** Machines, with Compound Ebonite Plates. List, one stamp.—Edwinstowe, Newark.

**Model Castings** in brass and iron, also Working Drawings for Horizontal, Vertical, Launch, and other Engines. Guaranteed best metal. Complete sets Castings from 1s. 3d.

**Separate Parts**, rough or finished. Castings from amateurs' own patterns. Catalogue, 2d. Six lithographed designs, 3d.—Hughes' "Mersey Dockyard," 17, Smith-street, Kirkdale, Liverpool.

**Castings**.—Half horse-power (Engine), Launch, Horizontal, or Vertical, ports in cylinder. Complete sets Forgings and Castings, 19s. 6d. One horse-power, 25s.—Tomlin, Highfield-terrace, Barnsley.

**Castings**.—Bench Drilling Machine Castings, 3s. 6d. Small Brass Horizontal Engine Castings, 2s. 6d. New Price-list and designs of perfect Castings post free.—I. Tomlin, Engineer, 28, Highfield-terrace, Barnsley, Yorkshire.

**French Polishing**, Staining, Painting, and Varnishing, 123 receipts or trade secrets, with full instructions and details, free 1s.—I. Tomlin, 28, Highfield-terrace, Barnsley Yorkshire.

**Cat Gut**.—Gut Hooks and Eyes for lathes and machinery.—James Bellaers. Regent-street, Leicester.

**Bellaers' Gas Stoves**, 1s. 3d., 2s. 3d., 3s. 3d., for boiling. Breakfast Stoves, 8s., 11s., 14s. 6d. Send for lists.

**Showcases** for Exhibitions, Models, Scientific Instruments. Exhibition Stands supplied and fitted.—Write, Fry and Hyatt, 90, Borough-road, London.

24 **Microscopic Slides**, in box, very cheap. List sent for stamp.—Well, Dalmain-road, Forest Hill.

Hand **Drilling Machine**, drills ⅜ holes 6 inches from edge, 25s. Photo 3 stamps.—S. Beeching, Mareham-le-Fen, Boston.

**Mica**, otherwise Talc.—RICHARD BAKER & CO., 9, Mincing-lane, London.

**Motor Castings**, materials for Electric Bells, Batteries, Galvanometers, Intensity Coils, Microphones.—King, Mendham, and Co., Bristol.

**Insulated Wire Table**, showing size, weight, resistance per foot, feet per ohm, &c., price 3d.—King, Mendham, and Co., Bristol.

**Standard Ohm**, in box, copper poles, guaranteed correct to ten thousandth of ohm, 21s.—King, Mendham, and Co., Bristol.

**Wimshurst Influence Machine**.—Sole Manufacturers of Improved Pattern. Numerous testimonials as to thorough efficiency.—King, Mendham, and Co., Bristol.

**Galvanometer Cards**, improved for tangent and ordinary combined, 2½in., 8d.; 4in., 10d.; 6in., 1s.; post free —As above.

Write for **King, Mendham, and Co.'s** large new and reduced Price List, post free 4 stamps.

**Catapults**, 7d., 1s., 1s. 2d.; elastic 2d., 3d. foot; square 1d. to 4d. yard.—Moody Bell. Cheltenham.

**Tricycle Wheels**, Bicycle Wheels, and Fittings Wonderfully cheap. Also for Safety Bicycles.—W. Gwinnett and Co., Wolverhampton.

**Edward W. Drury**, Hull, Glass Bottle and Cork Manufacturer, Importer of Chemicals, Caramel, Glucoses, Tinned Wire.

**Lathes**, Lathes. Cheapest and best. List, 2 stamps Nothing equal at price.—Robinson, Somerset-road, Sheffield.

100 **Foreign Stamps**, including Brunswick, Ceylon Tasmania, Egypt, Greece, Luxemburg, free 7d.—Hely, Foley-street, London.

Patent Spiral Grip **Letter Racks**. "An invaluable invention." Parcels post, 1s. 3d.—Iles, Highgate-street, Birmingham.

Pumphrey's **Pocket Tripod**, for cyclists, professional and amateur photographers. Perfectly rigid. May be had on approval. Illustrations and testimonials free.—Pumphrey, Stanhope-street, Birmingham.

The **Camera and Lantern**, with three instantaneous photographs; gives full instructions in their production; 6d. post.

**Camera and Lantern Apparatus**, dispenses with multiplicity of slides, 36 plates carried, changed anywhere.—Pumphrey, Birmingham.

Pumphrey's **Hydrostatic Shutter** gives instantaneous or timed exposures; 10s. Illustrations post free.—Pumphrey, Stanhope-street, Birmingham.

**Photography**. — Odd Backs, Leather and Cloth Bellows for sale.—E. Wills, 116, Rotherfield-street, N. Stamps for replies.

**Patents, Designs, and Trade Marks**. — For particulars of lowest charges, apply, G. L., Technical Bureau, 46, Queen Victoria-street, E.C.

**Battery**, for Electro-Plating, cheap in working, and will last for 200 hours without re-charging, and the consumption is almost nil when not at work. Price £25.—Britannia Co., Colchester.

**Lathe-Heads**, nearly new, 3-inch, 27s.; 3½, 53s.; 4-inch, 60s.; 5-inch, 80s. per pair, including hand rests and tees. —Britannia Company.

**Slide-Rests**, Improved Compound, several second-hand, and some nearly new. Give height of centre and section of your lathe bed.—Britannia Co.

**Cash Returned** if any article above mentioned are not approved. Similar heads and rests may be seen at our London Showroom, 99, Fenchurch-street. — All correspondence to Britannia Co., Colchester.

**Tricycle Parts**.—Complete Sets of Works for central geared, double driving, front steering, plain and ball bearings, steel tubes bent. Full instructions and working drawings. Wheels or any part finished to order.—Machines on view, and particulars of E. Edwards, 163, Kennington Park-road, London.

For sale, cheap, **Equatorial Telescope**, by Dancer, with 4-inch Wray's object glass, six eyepieces, &c., equal to new, maker's price, £90. Also an Observatory, recently erected, cost over £20.—Particulars from W. I. Chadwick, 13, Ellesmere-avenue, Eccles, near Manchester.

**New Time**.—Alter your Clocks and Watches. Twelve Sets of Figures, with instructions, 6d.—Wheeler, Preston.

**Water Motors**, for sewing machines, organettes, window advertisements, 32s., 42s. List one stamp.—Wheeler.

**Fan Castings**.—Improved Registered Designs; sets 6in., 3s.; 6in., 4s.; 8in., 5s. Drawings, 4d.—Wheeler, Engineer.

**Water Motors**.—Complete one horse-power, £9. Half, £6. Quarter, £4. Eighth, £3.—Thomas Wheeler, Preston.

Steel **Name Stamps**, 3d. per letter. Figures (set), 2s. 4d. Letters, 6s. 4d., per post.—E. F. Baldwin, Robinswood-hill, Gloucester.

**Launch Engine and Boiler**, 3in. bore, 4in. stroke, Vertical Tubular Boiler (19 tubes), 3ft. high, 1ft. 9in. diam. Price £35.—S. Smith.

**Screw Propellers** from 6in. to 30in. in stock. Improved pattern.—S. Smith, 11, West-street, Soho, W.

**Incandescent Carbon Lamps**, low resistance, 3s. each; Fairy Lamps, 3s. 6d.; Platinum Lamps, 1s. 3d., post free.—Todd, 14, Wentworth-road, Manor Park, Essex.

**Incandescent Lamp Holders**, new pattern, best in the trade, 12s. dozen; sample, post free, 1s. 3d.—Todd, as above.

**C. Pilkington**, 32, Sackville-street, Piccadilly, W., Magic Lantern Artist and Photographic Colourist.

Magic Lantern **Photograph Colouring**, finely and artistically done, 12s. per dozen. Special terms to the trade on application.—C. Pilkington, 32, Sackville-street, W.

Photography.—Splendid brass-bound 10 by 8 **Bellows** Camera, rack and pinion, 35s.—A. Smith, Union, Buckie.

**Engine and Boiler** combined, 6in. bore, 12in. stroke, by Green; very cheap.—Rigby Smith, Fazackerley, Chorley.

**Castings, Forgings** of a 2 by 3½ Horizontal Engine by Dorrington.—Walker, 54, Roe-lane, Southport.

**Ivory Tusk**, 2ft. 6in. long, 6in. circumference, 30s.—Mr. Lee, 3, Camden Cottages, Camden-road, N.W.

**Ivory**.—Round, 2-inch long, 1¼ thick, hollow; 6s. lb.; solid, 8s. lb.—Mr. Lee, 3, Camden Cottages, Camden-road, N.W.

**Marqueterie Panels**, Friezes, &c., high-class.—Mr. Lee, 3, Camden Cottages, Camden-road, N.W.

"**Knowledge**," to date, complete, £1. Induction Coil, ¼ inch spark, 18s.—Jas. Campbell, 158, Thomson-street, Dennistown, Glasgow.

**Contents of Amateur's Workshop**, including first-class back-geared gap bed Lathe, by Britannia Co., 3in. centres, slide-rest, scroll chuck, parallel vice, twist drills, stocks and dies, full set turning tools, &c., &c.—Apply, D. Simms, 5 Clarence-place, Belfast.

**Devonshire Cream**, delicious, by improved centrifugal process. Parcels Post, lb., 1s. 6d.—G. Bull, Manor Farm, Martock, Somerset.

**Planing**, not exceeding 10in. by 10in. by 8in.—B. W. Clegg, 18, Belinda-street, Hunslet, Leeds.

For **Model Work** (wheel-cutting in brass only); also Boring, Turning, and Screw-Cutting.—Clegg, as above.

Grant Bros.' parts of **Electrical Apparatus** of every description for amateurs; wholesale prices; full instructions free.

**Electric Bells**, Batteries, Pushes, Wire, wholesale prices; list free.—Grant Bros. and Co., 20, High Holborn.

Model **Engine Castings**.—Horizontal, Vertical, Beam, and Marine. List, 1 stamp.—Wood, Dalley-street, Broughton, Manchester.

**Dynamo**, 25 volts, 10 ampères, laminated armature, price 75s.—J., South Cottage, Thurlow Park-road, Dulwich.

**Changing Box**. Shew's, suit any ½ or ¼ camera, also Lancaster's Le Meritoire ¼-plate Lens, both in good condition.—Particulars, Braid, Livingstone, Midcalder.

Double Brass-finisher's **Lathe**, ½ H.-P. Boiler, Water Motor, Gas Bag, Marion's Cabinet Burnisher, Limelight Jet, Kettledrum, Air Gun Walking-cane, 2 Cameo Presses, Sundial. M. I. P. Bicycle Bag; must be sold.—Apply to Wm. B. Thomson, Wick, N.B.

**The Kinetic Engineering Company**, 36 and 37, Brooke-street, Holborn, London. Circulars and list post free.

**Dynamo Wire**, 1s. 2d. per lb. Line Wire, 29s. 6d. per mile. Pushes, 4s. per dozen.—Kinetic Company.

**Leclanche Cells**, best. No. 1, 16s.; No. 2, 19s.; No. 3, 22s. 6d. per dozen.—Kinetic Company.

**Electric Bells**.—Best quality, workmanship, appearance and value in market, 40s. per dozen.—Kinetic Engineering Company.

**Maiche Patent Battery**.—Best yet produced. Circulars and Scientific Reports post free.—Kinetic Engineering Company.

**Electrical Supplies**. Wholesale only.—Kinetic Engineering Company, 36 and 37, Brooke-street, Holborn. London, E.C.

Will sell my nearly new **Vertical Engine**, 1½ horse-power, for £8. Must sell.—J. H. Evans, 12, Rhys-street, Trealaw, Pontypridd, Glam.

Large Bottle Best **Gold Paint** direct from the manufacturers, post free, 8 stamps.—193, King Edward's-road.

Col. Ross's Patent **Filter Pipe**, price 1s. 6d., post free 1s. 8d.—G. Deal, 7, Holborn Viaduct, London, E.C.

The **Pipe of all Pipes**. Price 1s. 6d., post free, 1s. 8d.—See above.

Patronised by the **Prince of Wales**. Price 1s. 6d., post free 1s. 8d., at above address.

**Recommended** by the English Mechanic. Price 1s. 6d., post free 1s. 8d.—G. Deal, 7, Holborn Viaduct, London, E.C.

**A Sure Cure** for Dyspepsia and Heartburn. Col. Ross's Patent Filter Pipe.—See above.

**Selling by Thousands**.—Try one if you have not seen it. Price 1s. 6d., post free 1s. 8d.—G. Deal, 7, Holborn Viaduct, E.C.

Smoked all the World over.—**Col. Ross's Patent** Filter Pipe. Price 1s. 6d., post free 1s. 8d.—See above.

**Beware of Imitations**, useless and fraudulent. We sell only Col. Ross's Patent. Price 1s. 6d., post free, 1s. 8d.—G. Deal, 7, Holborn Viaduct, London, E.C.

**Col. Ross's Patent Filter Pipe**.—Look out for it at the "Inventories" Exhibition; meanwhile buy one of us.—G. Deal, 7, Holborn Viaduct, London, E.C.

**Boiled Oil**, quick dryer something new, full working instructions, 5s.—J. MURRAY, 6, Hamlet-street, Bootle, Liverpool.

Odd **Spiral Spring** made to order. Mattress Spring 9d. per dozen.—JAMES PARISH, 52, Bard-street Park, Sheffield.

"**English Mechanic**," Volumes I. to XXXIII., inclusive, unbound, 16 indexes, £3.—W. G., 17, South End, Croydon.

**Incandescent Lamps**, 8d., post free. Only a few left.—NEW and Co., 24, Dean-street, Soho.

See our 8s. **Electric Bell Set**. Wonder of the Age. —NEW and Co., 24, Dean street, Soho.

**Incandescent Lamp** in Gilt Scarf Pin, 20 stamps. —NEW and Co., 24, Dean street, Soho.

**Field Glasses**, Opera Glasses, Binocular Telescopes, &c., new and second-hand, very cheap. Also Microscopes, Stereoscopes, Chemical Apparatus, Electrical Apparatus, Photographic Apparatus, Model Engines, and every description of Scientific Apparatus cheap.—T. GORDON BOWMAN, 34, Compton-street, Brunswick-square, London.

A New Varnish.—**Spirit Copal**. Clear and as white as crystal. Dries in 5 minutes Sample, 7 stamps post free.—S., 5, Coventry-street, W., London.

For Dentists and Others.—**Stent's Pink Colour** COMPOSITION is the best for taking perfect impressions. Sample, 6 stamps post free.—5, Coventry-street, W., London.

**Square or Hexagon Articles**.—Full directions how to turn these in any ordinary lathe, including catalogue of lathes and parts of lathes. Any amateur can fit it up. Send eight stamps.—BRITANNIA Co., Colchester. Inventions Exhibition, 91 Stand, Main Avenue.

**Square Hole**.—How to cut square holes by hand tool. Anyone can do it. Eight stamps, including catalogue.—Amateur Department, BRITANNIA WORKS, Colchester.

Second-hand **Lathes** and various items. Give details of what you require. Stamped envelope for list of second-hand lathes, &c.—BRITANNIA Co.

**Note the Address**. — BRITANNIA COMPANY'S London Showrooms, 99, Fenchurch-street. All correspondence to Colchester.

Several nearly new **Lathes**, similar to those on view at 99, Fenchurch-street. Also Rests. Send details of what you require.—BRITANNIA WORKS, Colchester.

**Engineer's Tool Department**.—Lathes, Shapers, Planers.—BRITANNIA Co., Colchester. Makers to the British Government.

**Britannia Co.** exchange any articles unless made to order. Tools and Machinery to design.

10 cwt. Moore's Patent Block 15ft. **Lifting Chain**; also 1½-ton, new.—WESTON, Atkinson street, Stockton-on-Tees.

Two-row American Organ **Tubeboard**, Munroe voiced reeds, F scale, cheap.—RAY, 38, Giesbach-road, N.

**Ivory Label Stop-Knobs**, with sticks, variety names, 6d. each.—RAY, 38, Giesbach-road, N.

**Munroe Reeds**, voiced and unvoiced. Few treble half-sets.—RAY, 38, Giesbach-road, N.

Attraction for Shop Windows.—**Moving Clockwork** FIGURES, 10s. Photo, 3 stamps.—M., 14, Church-street, Oldbury.

**Engine**, ¼-horse, 35s.; 1-horse Boiler, 30s. Photo, 3 stamps.—M., 14, Church-street, Oldbury.

**Lathe**, 6in., back-gear, compound slide-rest, double-throw crank, 7-speed flywheel, V and flat bed, face-plate, £10, worth double.—LANE, 25, High-street, Peckham, Surrey.

**Tricycle House**, full size, portable, hold two bicycles, £5 10s., carriage paid.—X., 7, Clarence-street, Liverpool.

**Pianfortes** by all makers at 25 to 35 per cent. discount.—DAUNCEY, Stroud.

**Pianoforte**.—A good Pianette, walnut, warranted, 14 guineas.—DAUNCEY, Stroud.

"**See-Saw**" **Waltz**, post free 1s. 4d. All music at one-third marked price, post free.—T. W. DAUNCEY and SON, Music Sellers, Stroud, Gloucestershire.

Plated **Tubular Microscopes**, plainly showing animalculæ in water, post free 1s.—ARNOLD, Spring-grove, Kingston, Surrey.

A Model **Schooner Yacht**, 32 inches long, rigged complete, £1.—C. WEAVER, Enniskillen.

**Cyanotype Paper**, 4d. per sheet. Specimen and circular free.—HUMPHRIES, Photographer, 44, Cornwallis-road, Holloway, London.

**Gas Engine**, ½ H.-P., £30; 2 M.-P., £17; new Planing Machine, 6ft. 2in. by 2ft., £40; 10in. Screw-cutting Lathe, £40.—J. DEIGHTON, 15, Nelson-street, York.

**Lathe** (3½in. centre) and Appliances, good maker, perfect condition, £5 10s.—27, Mount Pleasant-road, Lewisham.

**Gas Engine**, two-horse, Crossley's new Silent Vertical. —LEE, 96, King's road, Camden-road, N.W.

**Gas Engine**, ½ horse, Crossley's Silent, with Siemens' 12-light dynamo.—LEE, 96, King's-road, Camden-road, N.W.

Model **Steam Engines** made or repaired. Separate parts fitted up, boilers made to order.—LUCAS and DAVIES, 21, Charles-street, Hatton-garden, London.

**Turret Clock**, high quality, latest improvements, few seconds variation in twelve months.—Full particulars. LEESON and SON, Steam Clock Works, Coleshill, near Birmingham.

**Fretwork Patterns**.—Will give some splendid patterns to every applicant. 1 stamp.—S. R. BROCKWAY, Marlborough.

48in. **Bicycle**, roller bearings, 50s. 50in. Bicycle, roller bearings, 60s.—WILLIAM SHACKLETON, 69, Avenue Parade, Accrington.

**Desmometer**, giving at sight weights of rivets and bolts of any size and length. Useful formulæ, 1s.—W. STEPHEN, 76, DeGrey-street, Newcastle-on-Tyne.

**Oxygen Gas**, compressed in cylinders, handiest and safest for limelight.—CLARKSON, Compressed Gas Chemist, Bartlett's-buildings, E.C.

**Oxygen Gas**, compressed into iron bottles, liquid nitrous oxide and carbonic acid.—CLARKSON, Compressed Gas Chemist.

**Oxygen Gas**, compressed into iron bottles; prices on application.—CLARKSON, 28, Bartlett's-buildings, Holborn, E.C.

Astronomical **Telescopes** of all kinds and Apparatus or Fittings made by A. CLARKSON, 28, Bartlett's-buildings.

**Eyepieces**.—Huyghenian of any power to fit any telescope, 15s. each. Sun Diagonals, £1. Star Diagonals, 30s.

Astronomical **Telescopes**, second-hand, by best makers.—CLARKSON, 28, Bartlett's-buildings, Holborn, E.C.

Splendid Black and Tan **Colley Dog**, price 30s., or exchange to 60s.—C. W. BICKLE, Stoke, Devonport.

**Lathe Heads**, Slide-rests, Beds, Cranks, Rests, Chucks, Appliances, rough or finished. Send for list.—W. R. SMELT.

**Models** for Patentees and Manufacturers accurately made to scale. High-class workmanship. Moderate prices.—W. R. SMELT.

**Turning**, Boring, Planing, Screw-cutting, Pattern-making. Forgings, on customers' own materials. Send sketch for estimate.—W. R. SMELT.

**Price List** of Lathes, Parts, and Castings, 1 stamp.—W. R. SMELT, Engineer and Tool Maker, 7, Goldsmith's-row, Gough-square, E.C.

For sale, a fine **Model Locomotive**, 3ft. 6 inches long by 13¾ inches wide, stands 1ft 6 inches high to top of boiler, all motions from foot plate; it is a powerful and beautifully made engine. Price £75. Photo.—GEO. F. NORTH, 2, Marlborough-place, Brighton.

**Microscopes**. — Apparatus, Alterations, Repairs, and Objectives. R. G. MASON (from J. Swift), Microscope Maker to the trade. All kinds of scientific instruments repaired. Stamp for list.—24, Park-road, Clapham, London, S.W.

A first-class pair **Launch Engines**, quite new, cylinders, 6 inches diameter; stroke, 8 inches; steel crank, &c.; stands 3ft. 6in. high, by about 2ft. 1in. square, on bed-plate, price £60; cost nearly double.—GEO. F. NORTH, 2, Marlborough-place, Brighton.

For sale, a beautiful **Steam Engine**, all bright, 1¼ bore, 2½ stroke metallic piston, double steel slides, double-ended connecting rod, with gibs and collars, gunmetal flywheel, with governors and throttle valve, in complete working order, bed painted imitation brickwork. Price £4; worth double.—WM. SMITH, 116, High-street, Dudley.

**Electric Billiard Markers**.—1 to mark 50, 1 to mark 100 game, double dials, well fitted works, only want polishing. What offers in Telephony or cash?—WM. SMITH, 116, High-street, Dudley.

Brequet **Hand Dynamo**, first offer taken; 10-light Dynamo, 5-light Oppermann Machine, new. Castings for small Machines and Motors. Inquiries invited.—WARNE, 39, St. John-street-road, E.C.

**Offers wanted** for two large cases of a beautiful variety of Butterflies, just received from India.—W. WAKEFIELD, Laurel-cottage, Lillington-road, Leamington.

52in. **Bicycle**, good, cost £7 15s.; will take £5 for it. Photo, 4 stamps.—CLARK, Watchmaker, Spennymoor.

**Organ Pipes**.—A widow whose husband was an organ builder has on hand a large quantity of pipes, &c., one Organ, nearly finished. All will be sold cheap. A bargain to builders. List for stamp.—Mrs. TATE, care of Clark, Watchmaker, Spennymoor.

What offers for genuine **Foreign Stamps**, value £5? Please reply by letter.—C. W. BICKLE, Stoke, Devonport.

Splendid 12in. polished steel **Fret Frame**, 1s. 6d. Six dozen best Fret Saws, 1s. 3d.—C. W. BICKLE, Stoke, Devonport.

**Photographs**, Scottish scenery, 7 by 4 inch, extraordinary value, 4d. each.—Address, PHOTO, 184, Trongate, Glasgow.

Clear **Gelatines** for tracing magic lantern slides, 3¼in. size, 4½d per doz.—Address, PHOTO, 184, Trongate, Glasgow.

**Gas Engines**, 1 to 4-man. Simple, strong, and cheap; nearly noiseless.—ELLIS BUTTERWORTH, Rochdale.

**Dynamos**, Jones's Patent, 2,122, working at 12, Old London, in International Inventions Exhibition. Motor Castings, 3s. a set.—H. JONES.

**Formulas Worked Out** for winding Dynamos from 10 c.-p. to 500 c.-p., 8 stamps each.—H. JONES.

**Dynamo Castings**, Jones's patent H: 8 c.-p., 5s.; 16, 5s. 6d.; 20, 6s. 6d.; 30, 7s.; 70, 16s. a set.—H. JONES.

**Dynamos**, finished: 8 c.-p., 30s.; 16, 36s.; 20, 40s.; 30, 50s.; 70, 100s. each.—H. JONES.

**Dynamo Armatures** of above wired after fitted up 1s. each, own make, warranted.—H. JONES.

**Dynamos** for house lighting. — Jones's Patent Laminated Fields and Armatures, 5, 6, and 7 lights, £6, £7, and £8 each.—H. JONES.

**Dynamo Machines Repaired**. Motors, with wire, 5s. 6d.—H. JONES, 48, High-street, Lambeth, S.E.

**Elastic Stockings**, Knee Caps, &c., best remedy for Varicose Veins, Swellings, Weakness, &c., from 3s. 6d. Directions for self measure free.—SMITH and SON, 6, Westborough, Scarborough.

Special **Circular** of Gramme Dynamo Castings and Parts, post free for stamp, from ALFRED CROFTS, Dover.

Improved Rocking Frame Adjustable **Brush Holders** for Dynamos. See circular, one stamp.—ALFRED CROFTS, Electrician, Dover.

**Battery**, Bichromate, new, double salt. No crystallisation in cells. See last week's advt.—R. A. LEE.

Chaster's **Electro-Motor Castings**, 3s. 6d. set. As described in "E.M.," 1026, 1027, and 1029.—R. A. LEE.

Patent Primary **Battery** for above, or 5 incandescent lamps. £3 10s.—R. A. LEE, 76, High Holborn, London, W.C.

Launch **Engine and Boiler**, 2 horse-power, also Castings from ½ h.—J. RESIDE, Brighouse.

**Launch Machinery**.—Complete set for 24ft. boat, £44.—VERRY and Co., Dover.

**Steam Launches**, 18ft., £78; 20ft., £90; 25ft., £110. Several in stock.—VERRY and Co., Dover.

**Launch Engines**, 3in. to 12in. cylinders, single and double, ready for delivery.—VERRY and Co., Dover.

**Dynamo Machine**, second-hand, 50 twenty-candle Lamps, cost £75. Price £40.

**Dynamo Machine**, second-hand, 30 twenty-candle Lamps, cost £50; take £26; splendid condition.—W. BANKS.

One H.-P. **Otto Gas Engine**, nearly new, cost, with fittings, £110. Price £90.—W. BANKS.

**Wimshurst Machines**, 17in. plate, half-gallon Leyden jars, best make, 7in. spark, 70s.—W. BANKS.

Small **Dynamo** to light six ten-candle lamps, with stand and driving arrangement, £8 10s.—W. BANKS.

Ebonite (Bell pattern) **Telephone Cases**, screw caps, best quality, 7s. 6d. pair, post free.—W. BANKS.

Banks' **Instantaneous Shutter** is the best yet produced; made entirely of metal; strong and light.—W. BANKS.

Banks' **Instantaneous Shutter** for a half-plate Lens can be carried in the waistcoat pocket.

Banks' **Instantaneous Shutter**, from its peculiar construction, is the quickest extant.—W. BANKS.

**Banks' Shutter** is cheap. 2in., 10s. 6d.; over 2in., 15s. Send for list.—33, Corporation-street, Bolton.

Vulcanised **Sheet Rubber**, nearly ⅛in. thick, 26lb, 2s. per lb.—CULVER, 143, London-road, Dover.

One H.-P. **Engine**, nearly new, strong, and in good repair, bargain, £3 10s.—WILLIAMS, Browne's Bat Works, Chelmsford.

Large ornamental **Aquarium**, hold 10 gallons, 20in. by 12in. by 13in., slate bottom, outlet pipe, gold and black, 20s.—SMITH, 72, Halliwell-road, Bolton.

The Amateur and Dentist's **Gas Engine**. Complete Castings, 42s. Drawing, 5s. Litho, 3 stamps.—A. DORRINGTON, West Gorton, Manchester.

Double-cylinder **Gas Engine**, impulse twice every revolution. Castings, 90s. Litho, 3 stamps.—A. DORRINGTON, West Gorton, Manchester.

Half horse-power Horizontal **Engine Castings**, ports in cylinders, 12s. 6d. Drawing, 18 stamps. Litho, 3 stamps. —A. DORRINGTON, West Gorton, Manchester.

Model Compound Condensing Marine **Screw Engine**. Castings, 18s. Litho, 3 stamps.—A. DORRINGTON, West Gorton, Manchester.

Make your own **Knife Cleaning Machines**. Castings, including Drawing, 5s. Drawing separate, 1s. 6d.—A. DORRINGTON, West Gorton, Manchester.

3in. or 4in. **Jaw Chuck Castings**, 3s. Forgings, 1s. 2d. Drawing, 6 stamps.—A. DORRINGTON, West Gorton, Manchester.

3in. back-geared **Lathe**, 2ft. 6in. bed. Castings 14s. 6d. Drawing, 18 stamps.—A. DORRINGTON, West Gorton Manchester.

Enclose stamp for **List** of Castings and Working Drawings.—A. DORRINGTON, West Gorton, Manchester.

## Wanted.

Old Microscopes, by Adams, Amici, Baker, Dollond B. Martin, Pritchard (Goring's "Engiscope"), Varley, and other old makers.—J. MAYALL, Junior, 224, Regent-street, London, W.

Birmingham Goods.—Jewellery, Watches, Clocks, Hardware, Harmoniums, Furniture. Agents wanted. Wholesale catalogues, 500 Illustrations free.—HENRY MAY, Merchant, Birmingham.

Agents Wanted on commission to sell a new Invention to users of steam power.—Apply SALFORD INJECTOR and EJECTOR Co., Salford.

Agents Wanted.—Morgan's celebrated Improved Scale Preventing Compound. Nothing better or cheaper.—W. H. MORGAN, Engineer, Gloucester.

Best Achromatic Microscope Wanted. Maker's name and particulars, lowest price for cash at once.—M. S., 5, Coventry-street, W., London.

Wanted, "Organ Voicing and Tuning," by Dickson or other.—K. G., 30, Stockwell-green, S.W.

Wanted to know how to Make Cement for Bicycle Wheels. Will pay for the information.—BICYCLE, 18, Milbourne-street, Blackpool.

Deer Horns Wanted.—M. DAY, Hook and Handle Manufacturer, 56, Driffield-road, Old Ford, London.

The advertiser wishes for Thorough Instruction in Lathe Work.—Apply, stating terms, to F. I. R., 7, Goldhurst-terrace, Hampstead.

Lathe wanted, screw cutting. 5in. centre, 4ft. gap bed. —J. DICKSON, 31, Spring-gardens, Edinburgh.

Wanted. Boiler Injector; no matter if out of repair.—WILLIAMS, Browne's Bat Works, Chelmsford.

## Addresses.

Wanted, Address of Agent for Foreign and Colonial Newspapers, &c.—M. THOMPSON, 2, Brookside-street, Oswaldtwistle.

Wanted, Address of Makers of Wood Boxes for Medical Coils.—JOSEPH CROOK, 77, Vernon-street, Bolton.

Address wanted.—Maker of small Japanned Tin Boxes (hinged).—WILSON, 12, Duncan-road, Southsea, Hants.

## THE INTERNATIONAL INVENTIONS EXHIBITION.

IF number and variety of objects can insure the success of the exhibition opened on Monday last at South Kensington, the Inventions will be at least as popular as the Healtheries, for since 1862 nothing like it has been seen in this country. It is well known, however, that many of the visitors are attracted by the music and by the brilliantly-illuminated gardens, which combined render the exhibition perhaps the most pleasant place in London in which to spend a few hours on a summer's evening. This year the buildings have been increased and extended; and by the formation of a subway from South Kensington Station, which enables the visitor to reach the exhibition without exposing himself to the weather, the executive council may fairly claim that they have also provided a place in which to spend a rainy day. Arrangements have also been made with the railway companies, and a useful guide enables persons residing within a radius of about 40 miles to readily ascertain the cost of a visit and the best means of making it. The exhibition is divided roughly into two divisions—Inventions and Musical Instruments; but while the former is confined to devices introduced since the Great Exhibition of 1862, the latter includes examples of a date not earlier than the beginning of the present century, though historical collections, either of instruments or drawings, are admitted. The progress of nearly a quarter of a century comes, then, under the head of inventions, and no one needs to be told that a great deal has been accomplished in that time: hence, there is in this exhibition something to interest everybody, and not a few objects which will attract the critical attention of experts. As the visitor enters by the Exhibition-road, or principal entrance, the first object that will probably attract his attention is a 12-ton 8in. breech-loading gun of steel, with the Stanhope lever arrangement for unlocking the breech, shown to illustrate the method used for working the larger guns. Close by is a trepanning bar, or boring tool, for removing the cores; of, or in other words boring out, the big guns. It is a hollow steel cylinder ¾in. thick and 16ft. long, fitted with cutting bits in its working face, which overlap each other, and provided with grooves, along which water is forced to cool the cutting edges and remove the shavings. The "tool" is fixed and the work revolves, the rate of cutting being 3in. an hour, while the solid cores which are cut out by the kerf formed by the bits are utilised in making smaller guns. The mechanic will readily compare this "tool" with the simpler lathe arrangement, which is shown in another part of the buildings, boring Lancaster gun barrels, and the novice even will readily appreciate the great advance which the 19th century has to show in machine tools. Another object which will attract attention in the War Department's exhibit is the breech of a 9·2in. gun, showing a portion of the breech end, with the Stanhope lever arrangement, and the special devices employed for working the gun in a heavy seaway or at extreme angles of elevation. There are many other objects in this exhibit which will secure attention, including the balloon equipment and the submarine mining or torpedo apparatus of the Royal Engineers. The Admiralty exhibit a number of devices used in connection with the naval service, including a Whitehead fish torpedo in full size and ditto in partial section. A number of machine guns, the Hotchkiss revolving cannon, and the new Maxim self-firing gun are also shown; but, in the last case, as the invention cannot be appreciated without seeing the gun in action, arrangements have been made for firing it in one of the iron buildings near the Queen's-gate entrance. The Maxim gun is one of the real novelties of the Exhibition, for it is a comparatively recent invention and one of the most interesting, for, once started, it will go on firing as long as cartridges are supplied to it, the force of the recoil being utilised to recharge it. If inventions for the destruction of life are numerous, it is satisfactory to find that there are many others devoted to the prevention of accidents; for besides such inventions as the Westinghouse and Vacuum brakes, there are several more or less automatic safety-couplings for railway waggons, and other devices for securing the greatest amount of protection in various dangerous employments. The Vacuum Brake Co. show their automatic arrangement as applied on the Great Northern Railway. A full-size footplate, with pipes and couplings to the vacuum and brake cylinders, has been fitted up, and a gauge indicates the degree of vacuum or the amount of pressure on the brake. The ball-valve coupling, which is arranged to separate easily if the train parts, is also fitted, and is occasionally separated to show the automatic action. A model of a G.N. 8ft. express and of the underframe of a six-wheel coach will enable the visitor to understand the arrangements. The Westinghouse Brake Co. exhibit their system as applied to a train of 15 coaches. In one corner of the stand is the air-pump and reservoir, and arranged at the back are the reservoirs and brake cylinders, all in full size, and connected so as to show the working through a train of that length. A driver's valve is placed in front, and when it is opened the rods connecting to the brakes are seen to rise simultaneously from the brake cylinders. A model of the underframe of a four-wheel coach is mounted on a short length of rail, and being fitted with the apparatus and brake blocks, the working is readily comprehended when the air-pressure is put on and taken off. The triple valve and couplings are also exhibited in full size, so that visitors can make themselves fully acquainted with the now famous brake. A specimen of Mr. Webb's compound locomotives is seen in the shape of the "Marchioness of Stafford," a brand-new engine, which forms a notable object in the Middle Court, where the majority of the exhibits connected with railways are shown. It is accompanied by a model of the "Dreadnought," a sister engine, which has already done very important work, for on March 19th, it ran from Euston to Carlisle with a load, including its own weight and that of the tender, of 207 tons, the consumption of fuel being 29·2lb. per mile, and the evaporation of water 9·49lb. per pound of coal. The distance is just a fraction over 300 miles. Mr. Webb also exhibits, in full-size, his duplex reversing gear for compound locomotives, by means of which the high and low pressure valves can be reversed together, or adjusted independently. A model six-wheel coach serves to explain Mr. Webb's method of using the air-pressure brake, and another of an eight-wheel coach exhibits his method of applying radial axle-boxes. Saxby and Farner exhibit in full size their safety lock for facing-points with duplex detector,—the signalman's cabin with fittings and the semaphore with its appurtances being also shown full size. McKenzie and Holland exhibit in full size their apparatus for working and interlocking railway points and signals at a station with level crossing, and, in model, a junction station with the method of interlocking the points and signals with the crossing gates and wickets. The Heberlein automatic friction brake is shown full size, so far as the acting parts are concerned, and there are several other brakes exhibited, possessing more or less ingenuity of construction, but which have little chance of employment in the face of the Westinghouse. Automatic and safety couplings are shown in some variety, many in large-size working models; but without drawings it is impossible to describe them. In view of the action recently taken in the United States in connection with safety couplings, it may be hoped that something will come of this public demonstration of the capabilities of some of the inventions, for the loss of life in marshalling goods trains is still deplorable. Of steam-engines there is a liberal display, many of them being utilised for driving machines, and several fitted with ropes instead of belts, while belting of various kinds is exhibited at work. Amongst the large engines under steam, a compound by the Messrs. Galloway, having the high-pressure superposed at an angle over the low-pressure cylinder, will attract attention; but the more interesting inventions in this class will be found in the new high-speed engines and in the improved valve-gears and automatic arrangements for expansion. Amongst gas engines there is one decided novelty in the shape of Atkinson's patent, exhibited by the British Gas Engine Co., while amongst those of the Otto type, shown by the Messrs. Crossley, there is one of the new two-cylinder engines, and one of the new vertical pattern. Two hot-air engines which will attract some attention, are shown respectively by Messrs. W. H. Bailey and the Britannia Company. Both are heated by gas, and while the former is at work pumping water, the latter is shown as suitable for driving a small lathe or a fret-saw. Those who are interested in agricultural machinery will find a good display in the South Court, and of machines in motion, employed in the work for which they are intended, there are enough to form a most attractive exhibition by themselves. Printing is well represented, both the *Graphic* and the *Illustrated London News* exhibiting machines producing work that is to be published, while there are many others, both litho and letterpress. In the machinery department a most interesting exhibit is that of Mr. Bell showing the methods employed in weaving and plaiting asbestos; but, perhaps, the most attractive exhibit of the class is that found in the gallery alloted to America, where the Waltham Watch Company show their wonderfully ingenious automatic machines for making the parts of watches. Amongst these is a train wheel cutter, which cuts out 40 wheels at a time; an escape wheel cutter, having two steel and four sapphire tools, which makes 50 wheels in about a quarter of an hour; a screw-making machine, which turns out finished screws at the rate of 400 an hour. Mr. S. Brooks exhibits machines for spinning and doubling cotton, including a "twist" ring spinning frame of 92 spindles, and a "weft" ring spinning frame of 84 spindles. He also exhibits the patent Ferguslie balling machine, which makes twelve balls simultaneously, containing any given length, at the rate of 250 yards a minute. Scouring, bleaching, and dyeing machinery; new laundry machines for various purposes, and others too numerous to mention here help to complete a most interesting exhibit. Of the musical instruments all that we can say here is that they form a splendid show, for while there are many, pianos for instance, exhibited only for their cases, there are several new or little-known inventions. Lovers of pipe-organs will find as many as they can properly examine in a day, though these are not all finished at present. Henry

Willis and Sons exhibit a large three-manual with pedals, without case, so that the mechanism of all parts can be inspected. Walker and Sons have a 4-manual with pneumatic, electro-pneumatic, and tubular pneumatic actions, but it is cased, as is the 3-manual instrument specially constructed by H. Jones and Sons for the Royal College of Music. We shall give the specification of this instrument, as it ought to be a typical specification for a concert organ of the size; but it may be mentioned here that it has a remarkably light touch without the use of the pneumatic action. Brindley and Foster show a model great organ of twelve speaking stops, one manual and pedal, with new tubular pneumatic action and improved pneumatic couplers; Bishop and Sons exhibit a church organ which is said to combine in one instrument the advantages of the Philharmonic and normal pitches; and Mr. Wedlake shows an organ of three manuals, with his new patent pneumatic action and improved double-action feeders. A few small chamber instruments are also exhibited; but the American organs or reed organs are almost as numerous as the pianos. Automatic instruments are shown in some variety, from the large orchestrion of Messrs. Imhof and Mukle, to one of the "perforated paper" toys, in which the working of the bellows, concertina fashion, is all that is necessary to "play any tune." Brass, string, and wood instruments are exhibited in considerable variety, and there is a considerable display of "fittings," which helps to make this part of the exhibition instructive. Of scientific apparatus and philosophical instruments there is so numerous a collection that it is almost impossible to even indicate them; but we may mention that all the recent inventions are well shown, and that M. Trouvé has intrusted to Mr. Aylmer a collection of his instruments and electrical apparatus, which will be shown in working order. The installation of the electric light will be the finest ever seen, and will include a great variety of machines and lamps, and at the same time give an opportunity for witnessing the performances of several high-speed engines, such as the Westinghouse, Armington and Sims, the Allen, the Willans, Mather and Platt, and such novelties as Goodfellow and Matthew's high-speed compound triplex, and the Tower spherical engine. "Old London" is to be lighted by arcs and glow-lamps, and with the shops occupied by weavers, makers of fancy goods, metal-workers, jewellers, lacemakers and embroiderers, engravers, &c., will form one of the most attractive sights in the Exhibition. We have endeavoured to give an idea of what is to be seen at the "Inventions," but we must obviously leave detailed explanations to future articles.

## ENGINE-MAKING AT HOME.—V.

### Miscellaneous Parts.

WITHIN the compass of this chapter I shall endeavour to embrace all that remains to be said about the construction of the engine patterns, and in succeeding articles give some hints on the fitting-up of their castings. The sketches being all dimensioned, their description will not occupy much time.

For the motion or guide bars (Figs. 51, 52), prepare the piece marked A to $\frac{7}{16}$in. thick, and cut as shown in plan, then rebate down at each end as indicated in the side view, this rebating being for the purpose of preventing the wearing of a shoulder near the ends by the slipper. Turn, and brad two circular facings, B B, on the back part, and two similar facings, C C, on the front. A curved strengthening rib D, will also be fastened on. Put a little taper in the rib, and tell the moulder to keep that in the top of the mould in order to insure sound metal in the facing.

The oil cup is made by fitting blocks E E against each side of the rib in the centre, and filling in between these and over the top of the rib with a strip of wood (Fig. 52, section). A print, F (section), is put on this, and a rectangular core box (Fig. 53) made to correspond. The same pattern will do for top and bottom motion bars without alteration, by providing a loose rib, exactly like the one on the pattern, for stopping off the oil cup by. A cover likewise (Fig. 54) to keep dust out of the cup, and a plain distance piece (Fig. 55) will be made. A special pattern will be required for the distance piece next the slide valve spindle, since that is made to take the spindle bearing (Fig. 56). The bearing piece is fitted to the distance piece, and the ribs which strengthen the casting also stiffen the pattern. It moulds with the faces A and B in top and bottom.

The cross head (Fig. 57) is proportioned for cast iron, but I should prefer to use wrought iron or gun metal on account of their superior tenacity. The pattern moulds as in plan, and is simply worked from a solid bit of mahogany, the piston rod end being turned first and the connecting rod end cut out with gouge and chisel. The slipper block (Fig. 58) consists of two pieces of wood only, and the inner or flanged portion is in the top of the mould.

The steam chest and slide valve are made like their castings. The sides and ends of the steam chest marked A, in the Fig. 59, are prepared and bradded together, and the back B fastened on, thus making a little open box. A shade of taper should be given within and without the sides. The flange C is prepared in four pieces, either mitred, or jointed with half-lap joints, or tenons at the corners, and fastened to the sides. The two strips, D D, for the valve, and those, E E, for fitting to the cylinder facing are not fastened with brads, but held loosely with skewers, which the moulder will pull out in due course. A facing, F, will be fastened to the back for the flange of the steam-pipe, and a ¾in. print—say, ½in. thick, will be fastened on the inside upon the same centre. The stuffing-box need not be made loose, provided it be cut as shown; neither will the flange be loose. The hole had better not be cored, being of small diameter.

The pattern valve (Fig. 60) is made thus: The middle block A is prepared to 2¾in. by 1⅝in. by 1⅛in., and cut without and within to the D outline (section) first. Then the outer pieces, B B, each 2¾in. by 1⅛in. by $\frac{3}{16}$in., are fastened against the sides of A, and worked to follow its outside contour. The blocks C C C are then fitted to the pattern and glued. When dry the hole D for the valve rod is cut through.

The steam chest gland (Fig. 61) consists of two pieces—one, A, cut to the oval shape; the other, B, turned and put on the flange with a stud.

Two cylinder covers (Figs. 62 and 63) are turned to the pattern dimensions out of dry, solid mahogany. The inner or cylinder faces will be turned first, the shoulders of which can be utilised for rechucking on the face plate when the outer faces are being turned. The bottom cover had better be turned to templet. The stuffing-box on the top cover should be turned separately and studded on, and its flange turned as a ring and dropped loosely over the print, as indicated in the section. The hole will be cored 1¼in. deep, leaving blank metal at the bottom, and a note to that effect must be made on the pattern for the moulder's guidance. The gland (Fig. 64) is made to dimensions given.

The piston pattern (Fig. 65) will consist of a plain disc. The recesses will be turned for the rings in the casting.

The eccentric sheave will be a solid pattern (Fig. 66), having a boss upon one side and a ¾in. print put on out of centre as shown. The grooves on the edge will be turned in the casting. The pattern of the strap (Fig. 67) will be cut out of a solid bit of mahogany, and the block A for the eccentric rod (Fig. 68) will be fitted separately, so that the one pattern (Fig. 67) will answer for the second (Fig. 68) with the addition of the block. Of the relations between the eccentric and the slide valve, I shall speak in connection with the details of fitting up.

The brasses for the connecting rod end being small (Fig. 69) are best cut from the solid, the grain running transversely to the bearing to avoid short grain in the flanges.

The pattern of the pump (Fig. 70) is turned in two portions A and B, each with its prints C, C, C. There is no need to joint so small a pattern. Make it of mahogany, the grain running longitudinally, and then the flanges may be turned out of the solid instead of going to the trouble of fitting them into recesses in the body after the fashion in larger patterns. The two portions A and B are fitted together at their junction with a gouge, glued, and allowed to set, then one fine screw on each side is put in diagonally to assist the glue. The two feet, D D, worked to the shape shown in Fig. 71, will be maintained loosely in place with a simple dowel in the centre. I should make this pump in gun metal. A core-box jointed longitudinally and dowelled will be worked out for the body core. Being small, it must be made in mahogany, marked out truly, and worked very carefully. Fig. 72 shows one-half of the box open in the joint.

In so small a pump I prefer to have the valve seatings distinct from the pump body. Fig. 73 shows a seating pattern, in section, made for bolting to the top and bottom flanges.

A plain flange (Fig. 74) will be wanted for the suction, and a flange with a short branch (Fig. 75) for the delivery. For the latter a small core box (Fig. 76) will be wanted. The small valve pattern (Fig. 77) is best turned in the cup chuck, and the wood between the feathers cut away before the pattern is detached from the chuck. The pump gland (Fig. 78) is made similarly to the other glands.

It will be observed that the glands and flanges look somewhat out of proportion to the size of the engine. But this cannot be avoided if we are to have sufficient metal to allow of screwing up without risk of fracture.

There must be no hard iron in any of these castings. Soft No. 1 Scotch, or a mixture of Scotch and scrap, both soft and tough, must be stipulated for, and the price paid. There are, I estimate, 106lb. of cast iron right through, and 18s. or £1 would not be too much for the set, provided they are good. Better pay that than 12s. or 14s. for a rough set. The brass will weigh about 6lb., not, however, including the pump, which would weigh about 1½lb, and is not, strictly speaking, brass at all, but gunmetal. This will cost 1s. a pound.

## SIMPLE EXERCISES IN TECHNICAL ANALYSIS.—VII.

By An Analytical Chemist.

### Black Paints.

(82.) THE black paints are so simple that it will not be necessary to do more than give the composition of a few average samples. Carbon black is the pigment chiefly employed; but it is not usually necessary to distinguish which kind of carbon black is used. The quality and suitability of the sample may be roughly judged by spreading a thin layer of the paint on a smooth board or a piece of paper. The loss on ignition of such paints includes both the carbon and the oil; and for ordinary purposes it is not necessary to estimate them separately.

MIXED BLACK PAINT.

(83.) *Composition*:—

| | | | | | |
|---|---|---|---|---|---|
| Oil and carbon .... | 20·50 | 21·5 | 19·6 | 21·7 | 23·4 |
| Sulphate of baryta | 28·15 | 28·1 | 31·8 | 41·4 | 38·5 |
| Oxide of iron .... | 16·25 | 14·0 | — | 9·0 | 9·5 |
| Chalk ............ | 35·10 | 36·4 | 48·6 | 27·9 | 28·6 |
| | 100 | 100 | 100 | 100 | 100 |

COMMON MIXED BLACK PAINT.

(84.) *Composition*:—

| | | | | |

ENGINE MAKING AT HOME.

(87.) The value of this paint depends principally on the percentage of oxide of iron which it contains. A very high percentage—60 or 70—is objectionable if the paint has to be kept a long time before being used, for such paints set very hard.

### Navy Black Paint.

(88.) *Composition* :—

| | |
|---|---|
| Oil and carbon | 84·70 |
| Insoluble silicates | 5·65 |
| Oxide of iron | 4·15 |
| Chalk | 5·50 |
| | 100· |

### Black Silicate Paint.

(89.) *Composition* :—

| | | |
|---|---|---|
| Oil and carbon | 19·3 | per cent. |
| Insoluble silicates | 71·86 | ,, |
| Chalk | 8·84 | ,, |

## Brown Paints.

(90.) The analysis of these will require no special description. We shall therefore content ourselves with giving the composition of a few samples. A ferruginous earth is the pigment usually employed.

### Mixed Brown Paint.

(91.) *Composition*:—

| | | | |
|---|---|---|---|
| Oil | 17 00 | 15 75 | 17·00 |
| Oxide of iron | 6·55 | 8 45 | 6·50 |
| Sulphate of baryta | 34·45 | 24·90 | 76·50 |
| Chalk | 42·00 | 50·90 | |
| | 100 | 100 | 100 |

### Mixed Chocolate Paint.

(92.) *Composition*:—

| | | | | |
|---|---|---|---|---|
| Oil | 14·05 | 14·7 | 15·7 | 11·5 |
| Oxide of iron | 81·00 | 41·0 | 38 0 | 84·3 |
| Insoluble silicates | 4 95 | — | — | 4·2 |
| Sulphate of baryta | — | 31·1 | 35 5 | — |
| Chalk | — | 13 2 | 10 8 | — |
| | 100 | 100 | 100 | 100·0 |

### Mixed Chocolate Oxide Paint.

(93.) *Composition*:—

| | | |
|---|---|---|
| Oil | 13·4 | 13·2 |
| Oxide of iron | 86 6 | 86 8 |
| | 100 0 | 100·0 |

## Other Paints.

### Lead Colour Paint.

(94.) *Composition*:—

| | | | | | |
|---|---|---|---|---|---|
| Oil and carbon | 23·1 | 19·3 | 22·2 | 15 95 | 20·1 |
| Sulphate of baryta | 29 0 | 30·5 | — | 21·50 | — |
| Chalk | 16·5 | 39·3 | 0 5 | 26·00 | 9·1 |
| Zinc white | 31·4 | 10·9 | — | — | — |
| White lead | — | — | 77·3 | 36 55 | 70·8 |
| | 100 | 100 | 100 | 100 | 100 |

### Buff Paint.

(95.) *Composition*:—

| | | |
|---|---|---|
| Oil | 14·75 | 13 8 |
| White lead<br>Colouring matter, viz.:—<br>Chrome yellow and red lead | 58 40 | 60·9 |
| Chalk | 26 85 | 25·3 |
| | 100 | 100 |

(96.) In the analysis of buff paints it would serve no useful purpose to endeavour to estimate the white lead separately when red lead is one of the pigments used. It is sufficient, therefore, for general purposes to estimate the oil and chalk carefully and the others by difference, the analyst satisfying himself of the nature of the latter by qualitative examination.

### Anti-Corrosion Paint.

(98.) *Composition*:—

| | | | | | |
|---|---|---|---|---|---|
| Insoluble silicates | 45 60 | 50 00 | 45·56 | 46·48 | 42·60 |
| White lead | 41·60 | 41·90 | 43·98 | 38·10 | 37·80 |
| Chalk | 5 04 | 4 48 | — | (+$Fe_2O_3$)8·10 | 12 50 |
| Alkaline sulphates (soluble in water) | 3 84 | — | — | — | — |
| Moisture | 1·92 | 3 62 | — | — | — |
| Carbon | 2 00 | | — | ·40 | ·42 |
| Zinc oxide, carbon, and moisture | — | — | 10 46 | — | — |
| Loss on ignition | — | — | — | 6 92 | 6·68 |
| | 100 | 100 | 100 | 100 | 100 |

### Grey Iron Paint.

(97.) *Composition* :—

| | | | |
|---|---|---|---|
| Insoluble silicates | 7 3 | — | — |
| Carbon | 2·6 | 5·15 | 3·2 |
| White lead | 20·1 | 10·74 | 8 8 |
| Oxide of iron | 7 8 | 19 60 | 20·1 |
| Chalk | 50·4 | 6 40 | 4·8 |
| Oxide of zinc | 11·8 | 21·27 | 12·0 |
| Sulphate of baryta | — | 36 84 | 51·1 |
| | 100 | 100 | 100 |

### Anti-fouling Composition (for Ships' Bottoms.)

(99.) *Composition* :—

| | | | | | |
|---|---|---|---|---|---|
| Naphtha and volatile matter | 5·92 | 6 30 | 36 23 | 45·45 | 39·74 |
| Oil | 25·24 | 27·44 | 26·95 | 36·92 | |
| Insoluble silicates | 1·90 | 1 73 | 6·56 | 1·89 | 1·63 |
| Oxide of iron | 2·30 | 2·75 | 24 20 | 6 93 | 2·26 |
| Chalk | — | 1·89 | 6 06 | 8 81 | 1 97 |
| Oxide of zinc | 61·25 | 55·76 | — | — | 51 05 |
| White lead | — | 4·13 | — | — | 3 35 |
| Oxile of lead | 3·39 | — | — | — | — |
| | 100 | 100 | 100 | 100 | 100 |

### Liquid Iron Paint.

(100.) *Composition* :—

| | |
|---|---|
| Oil | 47 98 |
| Insoluble | 43·15 (chiefly silicates) |
| Oxides of Iron and manganese | 8·87 |
| | 100 |

### Rose Pink Paint.

(101.) *Composition*:—

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| Moisture— | 13 4 | 8·75 | 20·30 | 9 60 | 26·52 | 23·40 | 24·82 |
| Organic colouring matter— | 17·5 | 9·35 | 18·70 | 18·55 | 19 08 | 14·36 | 15 50 |
| Chalk— | 60 3 | 73·55 | 55·15 | 62·35 | 45·62 | 55 84 | 52 66 |
| Alumina— | 8 8 | 8·35 | 5·85 | 9·50 | 8·78 | 6 40 | 7 02 |
| | 100 | 100 | 100 | 100 | 100 | 100 | 100 |

## New Paints.

(102.) *Composition* :—

| | "Albissima" Paint. | "Duresco." |
|---|---|---|
| Oil and turpentine | 16·74 | 43·22 |
| Sulphate of baryta | 43 92 | 43·32 |
| Oxysulphide of zinc | 39 34 | 10 40 |
| Oxides of iron and alumina | — | 1·72 |
| Chalk | — | 1·34 |
| | 100 | 100 |

### Driers for Above.

(103.) *Composition*:—

| | | |
|---|---|---|

(109) The composition of the samples given above will doubtless be useful to many. Some of these paints have been recently introduced some are not very common, but all are likely to be met with in commercial analysis.

It will be seen from the figures given that some of the paints are of no special value, and are in no way superior to those ordinarily used.

*(To be continued.)*

# A SIMPLE METHOD OF COLOURING AND ENAMELLING PHOTOGRAPHS.[*]

THE following method of colouring and enamelling prints has proved in the hands of those to whom I have given instructions of very great value (commercially). Excellent results are attained at once with very little labour and the minimum of art knowledge. It is not intended to replace any of the "legitimate" methods of colouring photographs, but rather to displace the "chrystoleum." At the first glance, it will strike many as being this process; but the results are so much finer, and with this difference, that the opaque and too dark parts of the photograph are capable of being coloured. This cannot be done with the chrystoleum, it being possible only to *tint through* the very light parts of the print. The operator will, after a few trials, be able to rival many of the laboriously-stippled photographs, and never risk losing the resemblance. I am convinced, also, a much greater degree of permanence is attained in the photograph itself by the treatment it undergoes. I have subjected prints thus treated, with one-half of the face covered with opaque paper in the printing frame, to the sun for many months, and at the end of the summer it was barely possible to detect the line of exposure. This was a test sufficiently severe, and convinced me that prints with the ordinary subdued light they are always viewed in would not suffer; the margin of the white mounting board suffered more from the exposure than did the coloured print, and was considerably bleached.

The following is a list of the requirements:—Fine pumice powder, such as used by dentists; two or three sable brushes—oil sables answer quite as well, and are very much cheaper than water-colour brushes; rose madder; orange vermilion, selected on account of its body; Chinese white (moist, in bottles); Indian red (for body). These few colours are all that are necessary for flesh; other colours may be added for hair, draperies, &c., as required. A piece of thick boiler-plate iron, say about 8 by 6 inches; several sheets of blotting paper, white; solid paraffin (wax); paraffin oil; cotton-wool; gelatine, Nelson's No. 1; enamel collodion; flannel to filter. First prepare the glass plate with the enamel collodion and gelatine (those who have not previously done this, see instructions at end), then take an unmounted print, lay it down on the blotting-paper, and with the tip of the finger, freed from grease, rub with a little pumice powder, and with a circular motion, very gently on the face and hands only, to give a slight tooth for the colouring; do not abrade the surface or destroy any half-tone. Now wash the face with a brush and clean water, and pass the tongue over it. As soon as dry, give a flat wash all over the face, eyes and all, with a flesh tint of rose madder and orange vermilion. As soon as dry (which will be by the time another print is thus prepared), clean out the eyes with the brush nearly dry. Now take body colour, and colour such parts as brooches or any portion that comes too dark in the photograph, on the albumen surface, using a little of the Chinese white in the body colour, and put in all high-lights of lace, &c.; also tint the lips, which are too dark, the upper one especially, with rose madder and Indian red. All this may be done in less time than is required to write it, and is all that is required to be done on the surface.

The next proceeding is to wax and make transparent the print, which also binds the colour already on. This is effected thus: place the print face down on several thicknesses of blotting-paper placed on the heated iron plate, and with the solid block of paraffin rub over the back; if the iron be sufficiently heated, in a minute or so the wax will permeate the print and render it very transparent; let it be thoroughly saturated, and immediately with a clean cloth remove all superfluous wax from the back and front. Now take a pledget of cotton-wool, and with the paraffin oil rub lightly both sides; allow it to soak well in for two or three minutes. With clean cloth rub off all the oil, and dip it entirely in the melted gelatine (prepared as at end), and squeeze it on the glass previously prepared with the enamel collodion. Wash all gelatine off the back with a sponge and warm water; there will now be no greasiness, and the glass can be placed on a retouching desk with a sheet of white card as a reflector, and coloured at the back. The face may now have the under lip and cheeks coloured, and the hair, ribbons, &c., and can be examined for the complexion by placing a piece of white paper closely pressed behind it. It will rarely require more colour on the face than the carnations, unless the first colouring on the albumen has been too pale. The draperies and background may now have very strong colour on to tell through the tone of the photograph, but the colour on the face should be very delicate, as when finally backed up they appear much stronger. When the colour is dry again pass over the paraffin oil, this time lightly dabbing it only; allow it to remain three minutes, and as carefully dab off with clean cotton. Do not rub it, or the colour will be disturbed. The thin mounting board, such as is used for enamelled print, is now gelatinised and squeezeed to the coloured print, and left till thoroughly dry. The object of this last application of paraffin oil is to prevent the possibility of the squeezeing disturbing the colour. Do not attempt to strip it from the glass until thoroughly dry (say next morning), then mount it in the usual manner by gluing about one-eighth of an inch round the edge of the thin cardboard after trimming, then place under pressure. The following method of preparing the enamelled surface on the glass sheets will be found a simple and certain one. Procure a sheet of plate glass free from scratches. The most useful size is 12½ inches by 9; this size will take several cabinets, promenades, or cartes without waste of enamelled surface. With a file or emery cloth rough about one-eighth of an inch all round the edges, to prevent the prints leaving the glass before quite dry. Rub the glass (when new) several times with waxing solution:—

---

[*] By T. G. Whaite, in the *Photographic News*.

| | |
|---|---|
| Best yellow wax .......... | 5 grains |
| Benzole .................. | 1 ounce |

Rub it on with a pad of tissue paper, and with another pad rub off, and finally polish with the palm of the hand, removing all that is possible in this manner, or streaks in the enamelled surface will show.

A piece of new glass requires treating thus several times before it is suitable for receiving the prints; afterwards, one rubbing on and off is all that is required. The glasses must never be washed after stripping, but be kept out of the dust, and any bits of film left on the margin rubbed off before re-waxing. Now coat with the enamel collodion, either purchased or made thus:—

| | |
|---|---|
| Gun-cotton.............. | ½ ounce |
| Meth. alcohol............ | 45 ounces |
| Meth. ether.............. | 25 „ |
| And a few drops of castor oil. | |

After coating, leave in a dry place until set well, and all the ether has passed off; then pour over in the same manner the warm gelatine solution, having been previously filtered through flannel. The gelatinising solution is thus composed:—

| | |
|---|---|
| Nelson's No. 1 gelatine .. | 1 pound |
| Water .................... | 128 ounces |
| Meth. spirit.............. | 40 „ |
| Glycerine................ | 1½ „ |

Soak the gelatine first, then warm, and filter. The prints may be laid on this as soon as set if necessary, but a better surface is obtained if allowed to dry.

It is important in colouring to remember to clear out the high lights at the back from forehead, &c. This leaves only the first colouring on the albumen to tint the lights, which will be found quite sufficient, otherwise the face will have a flushed look when backed up with the cardboard. Every necessary detail is explained here, and if followed closely failure is impossible, and will be found, after one rehearsal, a rapid and extremely simple method.

## SAND SOAP AND TRANSPARENT SOAP.

ACCORDING to the *Seifensieder Zeitung*, under the name of sand soap a new detergent of peculiar appearance and composition, of English origin, has been recently placed upon the market. It is greyish white in colour, heavy as stone, and rough and sandy to the touch; on rubbing the hands with it, particles of sand adhere to the skin. It is, in fact, an intimate mixture of fine sand with ordinary soap. In order to ascertain its composition, the writer has subjected it to analysis, and finds it to contain 70 per cent. of fine sand; the saponified fat was palm oil. Experiments showed it to have no disagreeable or damaging effect on the hands when used as a detergent, and proved it, moreover, to be an excellent cleansing soap, especially suited for the use of workmen engaged in rough and dirty vocations. The author has made various experiments with a view to ascertain the maximum amount of sand which a soap of this kind can take up, and finds that 100 parts of soap can take up 200 parts of sand, but it is not advisable to add the full quantity, as the mixture will no longer lather properly. To make a good "sand soap," the author recommends the following method: 100lb. of cocoanut oil are saponified with about 200lb. of lye at 20° B. The soap is then hardened by the addition of about 8lb. salt dissolved in water to a density of 15° B., with the addition of 6lb. to 8lb. soda ash. The soap is now covered up, and the foam allowed to subside. After standing five to six hours, the fob is skimmed, and the soap is run off into the coolers. While this process has been going on the sand has been dried and sifted, and, the soap now being thoroughly crutched, the sand is sifted over it, until 100lb. to 150lb. have been added. The crutching must be continued until the mass is perfectly cooled. The soap is very firm and hard, and must be cut as soon as cooled. To perfume the mixture add of essential oil of lavender, thyme, and coriander 100 grammes each.

### Transparent Glycerine Soap.

The manufacture of transparent glycerine soap does not present any special difficulty; there are, nevertheless, points which it is essential to observe. To produce first-class soap of this kind good materials are indispensable, and the proper proportions must be strictly adhered to. Tallow and stearine are the most useful hard fats, palm oil imparts to the soap its lathering qualities, and castor oil gives transparency. Great transparency is attained by the use of spirit and of sugar-water, both of which bodies assist the normal saponification. The lye must be pure and clear as water; its proportion should not exceed 20 per cent. of lye per pound of fatty matter, for an excess of alkali would make the soap too detergent, and a considerable excess of unsaponified fat would make it too weak and greasy. In one case the soap injures the skin in use, in the other the soap would soon lose its agreeable smell, and finally become rancid. Even an excess of glycerine is to be avoided, as it renders the soap less transparent, and also too soft. No filling whatever, except sugar solution, is permissible. The following proportions are recommended:

### White Alabaster Soap.

Stearine, 13lb.; palm oil, 22lb.; glycerine, 13lb.; 38° lye, 18lb.; 96 per cent. alcohol, 26lb. The stearine and palm oil are to be heated to 65°, saponified with the lye, the alcohol added, and when the combinination, which takes place at once, is complete the glycerine is put in. When clear, the kettle is covered, and the contents are allowed to stand at 45° R. The soap is run into the moulds, and perfumed with bergamot oil, 120grm.; geranium oil, 30grm.; neroli oil, 24grm.; citron oil, 30grm. As this is a white soap, no colour is added.

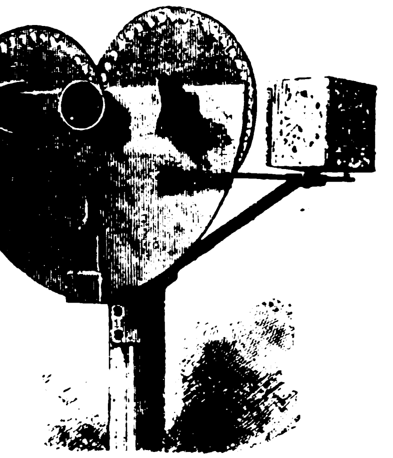
### Transparent Soap.

Tallow, 20lb.; palm oil, 12lb.; castor oil, 8lb.; 38° lye, 20lb.; spirit, 20lb.; glycerine, 20lb.; sugar dissolved in, 5lb.; water, 5lb. Process as above. Perfume with oil of bergamot, 250grm.; citron, 90grm.; lavender, 20grm.; neroli, 30grm.; rosemary, 5grm.; and a few drops of otto of roses, dissolved in 1lb. of 96° alcohol; colour with saffron substitute.

## COMPOUND OPTOMETER FOR CORRECTING ERRORS OF REFRACTION.

IN making examinations of the eye for the purpose of determining its refraction and the adaptation of spectacles to correct defects which may exist, the first part of the process is to determine visual acuteness. Letters are placed before the individual whose eye is being examined of varying sizes; some to be seen by the normal eye under a visual angle of 5' at 200ft., and from that down to the distance at which the letters are from the observer. In order that the refraction of the eye be correctly measured, it must be in a state of rest—adjusted for parallel rays; and this ophthalmologists claim can only be secured by placing objects to be observed at a distance, and 20ft. has been accepted as the distance which practically accomplishes this object. But it is claimed that the optometer herewith illustrated renders rays emanating from objects placed at 13in. from the eye parallel, and consequently measures the refraction perfectly. Lack of visual acuteness may be due to a defect in the perceptive part of the eye, the retina, or to a refractive anomaly. To determine this a concave and a convex lens, about one-thirtieth, are alternately placed before the eye, and if either improves the vision there is either myopia or hypermetropia. The number of the glass that produces the greatest visual acuteness measures the refractive error. If neither the concave nor convex lens increases the visual acuteness, the test for astigmatism is made, and when none of these tests improves vision the defect is in the retina. This is the procedure followed by occulists, and while being correct theoretically and in its practical results, it is stated to be awkward and tedious when compared with the optometer.

The optometer shown in the accompanying engraving has an upright of about 12in., upon which are mounted two circular discs, one for spherical and the other for cylindrical lenses. Each disc can be so revolved that the lenses can be brought in front of a common opening or eye tube, through which the observer sees letters. The disc containing the cylindrical lenses is attached to an arm, by which it has a movement besides the one upon its central axis, and whereby the axes of its cylindrical lenses can be placed in any degree of a circle before the eye tube. The discs are so situated that the lenses of one can be interposed with that of the other, thus combining their effect if necessary. Upon the extremity of a horizontal bar attached to the upright, about 12in. in length, rests a card rack, in which the test letters are placed 13in. from the observer's eye.



The spherical lenses are 38 in number, 19 concave and 19 convex, embracing a series from $\frac{1}{74}$ to $\frac{1}{4\cdot5}$. Intervening between either extremity of the positive and negative lenses is a plain glass. The disc containing the cylindrical lenses has the same arrangement as the one containing the spherical, as mentioned above. There is an eyepiece for the eye being examined, while the other will be deeply shaded, thus practically disposing of the inclination to convergence. The reason for this is that convergence and accommodation are co-ordinate acts, and in this case by controlling the convergence the tendency to accommodate is also greatly controlled.

At the extremity of the eye tube, and with the centre of its system, about 2in. from the cornea, as it rests in the eyepiece, is placed an objective which is a compound achromatic lens, the principal focus of which falls on the test letters on the card. This practically produces a myopia of $\frac{1}{11}$. The rays proceeding from the objective to the eye are of necessity parallel, since the test letters are at the principal focus of the objective. It is claimed that this disposes of the objection to the instrument by those who state that it will not relax accommodation. Placing the objective outside of the anterior focal distance of the dioptric media of the eye magnifies the letters to be observed, but this in no way changes the results of the test for refraction, but the letters used should be proportionately small, if a test for visual acuteness be made, else the visual angle of 5' will be changed; if the letters are magnified one-half, they should be one-half smaller.

In the construction of the system for measuring visual acuteness with this optometer, a letter is used for a basis, the measurement of whose diameters forms the base of an angle of 5", the distance from the centre of the system of the objective to the letters forming the sides of the angle. If the eye were placed at 11in. from the letters, they would be the same size as the objective renders them at 13in., so that the visual angle is measured from the centre of the system rather than from the position of the cornea. The letter, then, at 11in. should have a diameter of $\frac{11}{60}$ of a line, or for practical purposes $\frac{1}{5}$ of a line. For the purpose of keeping a record of visual acuteness, as by the method of Snellen, when the smallest letters can be read, which are $\frac{1}{5}$ of a line in diameter, it may be stated that $V = \frac{20}{20}$. When the next letters, which are one-half larger, are the smallest that can be read. V may be marked $\frac{20}{40}$, and so on up to 200ft. This optometer, which is the result of several years of careful study and experiment, has been patented, and is now manufactured, by Mr. L. A. Berteling, of 427, Kearny-street, San Francisco, Cal.—*Scientific American.*

# WHEAT-MEAL BREAD: ITS ALIMENTARY VALUE COMPARED WITH THAT OF WHITE-FLOUR BREAD.*

By Dr. Campbell Morfit, F.I.C., F.C.S.

THERE is such a diversity of chemical opinion as respects the nourishing potentiality of wheat-meal breads, that a satisfactory solution of the question by chemical analysis alone would seem to be difficult, for the present at least. But if we leave the chemists disputing amongst themselves, and pass from the domain of speculative philosophy on to the safer ground of practical science, mystification is seen to clear away at once, and there is revealed to us by the logic of facts the true state of the case, which I will now endeavour to explain.

Whole wheat-meal bread was the kind upon which the Roman army fed in the time of Julius Cœsar; and in the earlier part of this century Dr. Sylvester Graham, of New England, recommended its use in the United States, where it is now known as Graham bread, and is highly appreciated by bread consumers generally. But until I made the process for the granular form of wheat meal and gave it to the London Bread Reform League, whole meal was coarsely ground and contained its bran as dense flattened scales with sharp points and rough edges, which rendered it irritable to digestive organs the least sensitive. My improvement, which removed these defects entirely, secured for the granular meal a widespread popular favour that has not become universal only because the millers and bakers, failing to understand the philosophy of its manufacture, allow both it and its bread to degenerate into irregularities. Granular wheat meal, unlike the ordinary whole meal, not only makes more toothsome breads, but insures the maximum degree of assimilation, because it is without that mechanically stimulating effect which hurries the whole meal through the alimentary duct before it has had time to yield all its nourishing matter to absorption. Whatever small portion may be excreted has yet acted an essential part in the process of digestion at least, though we may not be able to define it at present.

There are chemists who encourage a wasteful mode of milling by repudiating the long-accepted doctrine as respects the physiological relation of the nitrogenous compounds of wheat. Their scientific contention not only splite the nitrogenous matter of food substances into divers phases with differential properties, but apportions to each a differential estimate of its nourishing capabilities. One of their tenets in this connection is that, however much nitrogenous matter may be present, only that portion of it distinguished by them as albuminoid, and which exists as protein (the basis of albumen, casein, fibrin, and the like), is potential for the nourishment of mankind. Indeed, some go so far as to suggest that even a part of the albuminoid nitrogen is of doubtful efficiency in that respect; and dividing the nitrogenous matter into two phases, one coagulable by acids and the other not, they throw out the latter as unavailable food matter. Its proportion may and does vary so widely in the same kind of food as to amount to as little as 5 per cent. in some samples of wheat, and rises to 34 per cent. in others; but these great discrepancies do not affect their judgment in the least. By this social arrangement in chemistry they ostracise nuclein, plastin, and their congeners, as dietetic pariahs; and in the case of wheat, they would relegate to the cattle-food bin all of the branny portion which, though representing about a fifth of the total nitrogen of the grain, contains most of it in other phases than the albuminoid—notwithstanding, too, that it carries with it most of the fat and phosphates, and the whole of the cerealine, the digestive ferment natural to the grain.

But while convinced by recent experiences that every part of the wheat grain is food for mankind, I know also that a portion of the branny integument, amounting to 6 per cent. of the whole grain, detracts from the toothsomeness of the baked loaf. Practically, therefore, this tough husky modicum is objectionable in a bread sense, and decortication does not remove it, nor can it be separated from the meal when the wheat grain has been ground in a steel mill. My old process conceded to the Bread Reform League, consequently, must be discarded, because it involves both decortication and the use of steel mills. I now not only make the elimination of the tough bran an incident of the grinding operation, and save any outlay for the purpose, but simultaneously render the tender portion yet more loose and soft in texture, and consequently am able to produce at the minimum of waste and cost, firstly, a standard granular meal of refined character, representing from 93 to 94 per cent. of the cleaned grain, and always uniform in quality and features; and, secondly, a pearl-white meal representing all the farina of the grain with some cerealine, or about 83 per cent. of the whole, and affording a superior material for a white loaf to excel the "household" bread of the bakers. The perfection of these meals faciliated my subsequent improvements in bread-making, and the two combined not only accomplished a saving of 10 to 13 per cent. in the milling operations, but will supply standard meals and breads at less cost than usual.

As yet the public have not had the opportunity for testing the great advantages of genuine wheat-meal breads, because bakers in this country are unable or unwilling to make them properly, and millers do not supply suitable meals. Wheat-meal bread as it should be is attractive in appearance, and very unlike the poor stuff sold as such in the London shops. Whether made by fermentation or without, its basis is granular meal free from any of the usual admixtures or substitutes of white dough or dusted bran and white flour. Its crust is tender and smoothly granular, instead of being rough and hard, and, in the case of fermentation breads, deliciously crisp. The crumb, vesiculated, light, and elastic, is never sodden or too close, becomes stale slowly, has a rich mealy taste, and when chewed excites the salivary secretion. The bran particles are invisible to the eye, even through a magnifying-glass, and, save that they impart an agreeable taste, scarcely betray their presence to the tongue. The outward features and inherent qualities of the breads of my system are characteristic and uniformly the same. Not only are they appetising, but, weight for weight, much more nourishing than white-flour breads.

In realising this standard excellence for meals and breads I employ only the usual means, but manage them in unusual ways so as to produce new and important effects. Success is obtained in my system of procedure, not by adopting the dogmas of those chemists whose cult is the aristocratic albuminoids, but by practising a rational philosophy of conflict with them. I act upon my belief that each food substance carries, naturally, an adjuvant of digestive ferments peculiar to itself, as wheat bears cerealine, which, when loosened from its bonds by compatible means, receives the impulse to co-operate in preparing its associate constituents for digestibility in the human stomach. The observance of this principle has enabled me to convert even milk into a cheese of characteristic toothsomeness and digestibility, chiefly because the latter reclaims and embodies the wealth of essentials now run to waste in the whey. Even my pearl meal, therefore, is made to retain as much as possible of the cerealine matter of the wheat; and when either it or the granular meal is mixed into dough, water is made to set free the digestive ferment for action. This done, the dough, without being touched with the hands, is partitioned in a manner to protect it against injurious influences or changes during fermentation in any weather, and to insure its perfect cooking in the oven without risk of spoiling a loaf by scorching or otherwise. The water is confined within the loaf until it has co-operated with the cerealine in developing the digestibility of the dough, and in promoting the baking or rather cooking of it into perfect bread; so that the portion necessary for its constitution remains in the loaf as a fixture, the excess passing off only when it has done its part in the cooking.

The crumb and crust of the breads made by my system contradict impressively the arguments against whole-wheat meal. But chemical analysis obtains so little interpreting assistance from physiological research in the premises, that it occurred to me to seek a fuller understanding of the subject in a way quite different from any hitherto conceived. That is, having satisfied myself, by oft-repeated practical experiments, that standard breads in every respect can be made with wheat meals, I contrived a method which, though not strictly classical, is one of practical science, for determining what modifications their material undergoes during conversion into bread to render them characteristically superior to any others of the kind. Four different typical wheats (two white and two red) having been selected and first made into three meals—viz., one crude, representing the entire grain; another, the standard granular of my system; and a third, the pearl meal or *farina consols*, also of my system, both of which have been already described—these meals were then converted severally, and according to my system, into non-ferment and fermentation breads. Scrupulous exactitude was observed as to all the weighings, dryings, and other manipulations, in order to make the results as trustworthy as possible.

The first step was to ascertain the exact proportion of total branny matter in the several meals; and for this purpose a given weight of each was carefully but thoroughly brushed upon a very fine wire cloth until all its farinaceous portion had passed through. That which remained on the sieve, being directed from the meal, was designated *proximate bran*, and it varied in proportion, according to the kind of wheat, from 16·80 to 19·30 per cent. of the crude meal, and 10·28 to 13·24 per cent. of the standard meal, or a mean of 18·23 per cent. for the former and 12·10 per cent. for the latter. Therefore, wheats generally may be said to consist of 81·72 farina and 18·28 branny matter per cent. The proximate brans of the different samples of crude and standard meals were next inclosed, separately, in very fine, white cotton cloths, and kneaded under relays of cool water until the latter ceased to become the least cloudy, and by this treatment they were reduced in weight rather more than one-half. The residue left I distinguish by the name of *absolute bran*, because it has parted with all its matter separable by the means employed. It will thus be seen that cool water alone has taken out of the proximate bran and into solution or intimate suspension upwards of 50 per cent. of its original substance. And what is no less remarkable, the ratio of absolute bran to the meal is a uniform fixed quantity for all the wheats indifferently, being 9·65 per cent. from the crude and 5·80 per cent. from the standard meal, notwithstanding that the proximate brans, whence they were derived, are variable in their quantitative relations to the meals. Therefore the total of actual bran in any wheat does not exceed 10 per cent.

Not yet satisfied that this absolute bran was exhausted, I next proceeded to ascertain if the proximate bran would yield more of its substance to artificial digestion than it does to water; and therefore it was subjected, under proper conditions, to the action of diastase, pancreatin, and pepsin consecutively. The result proved that the 9·65 per cent. of absolute bran from the crude meals had become reduced to 7·87, or 18·44 per cent.; and in like manner the 5·80 per cent. of absolute bran of the standard meals lost 21·38 per cent., having been lowered to 4·56—except for one of the red wheats, which gave rather less difference for both meals, and seemed to be erratic. As this residue could not be resolved further by any controllable means, it takes, logically, the title of *ultimate bran*; and it would represent the final state and proportion of the bran if the process of artificial digestion left it free from variable quantities of associate matter. But digestion outside of the human stomach does not correspond with that inside, however skilfully it may be imitated, for there is some force at work in the one case which cannot be commanded in the other; and probably, therefore, yet more of the bran is assimilable under more natural conditions. At the worst, the standard granular meal of my system has only 4·56 per cent. of undigestible matter. Very interesting, too, in this connection is the fact that this absolute bran not only loses density in becoming ultimate bran, but also drops as respects its mineral matter from 5·36 to 0·33 per cent. for the crude meal, and from 4·33 to 0·43 per cent. of the standard meal; or, in other words, the 2·42 and 2·36 of phosphoric acid which they represent fall nearly to zero, being drawn out by the process of digestion. Moreover, the total nitrogen, 2·17 per cent. (containing albuminoid nitrogen, 1·80), of the crude meal brans becomes 0·82 (containing albuminoid nitrogen, 0·78); and under corresponding circumstances the total nitrogen, 1·92 per cent. (containing albuminoid nitrogen, 1·86), of the standard meal brans falls to 0·80 per cent. (containing 0·80 albuminoid). Thus, although artificial digestion draws out the whole of the phosphates or mineral matter, and 60 to 70 per cent. of the nitrogenous matter, that portion of the latter which it leaves is—wonderful to be told—all or nearly all albuminoid.

Results could not be more impressive than these as to the superior nourishing value of whole wheat meal, for they prove that the separation and rejection of the bran must inevitably impoverish the residual farina or flour. This fact obtains additional confirmation in my own every-day life, for whole-meal bread, which forms four-fifths of my restricted diet, nourishes me satisfactorily; whereas any attempt to vary it in the least, with fine white flour bread, brings back bodily discomfort and debility. In the course of my laboratory work upon this subject, I also learned that, unusually fine as are the fermentation breads of my system, non-ferment breads can be made to excel them in every respect. But it is necessary to follow throughout a strictly philosophical method, and then they will require less time and labour in their manufacture, be independent of a choice of wheats, and always sweet and appetising. "Baking powders," however, must not be employed for generating the carbonic-acid gas which is to vesiculate the dough, as they leave chemical residues in the baked loaf which render it unwholesome. Nor must the carbonic-acid gas be dissolved in the water for mixing the dough and forced in mechanically, for though it will aërate the loaf, it will not produce perfect bread. To promote the hydrolysis whereby the cerealine with water replaces yeast, leaven, and fermentation, and to facilitate the osmotic action upon which the metamorphosis of dough into bread largely depends, the carbonic acid gas must be in the nascent state and generated within the dough.

# LUBRICATING OILS AND THE COEFFICIENT OF FRICTION.

AT a recent meeting of the American Association of Mechanical Engineers Dr. Arvin read a paper on the subject of lubrication, from which we extract the following:—

To a practical man who wants to know what he needs to put upon his engine, the value of "the co-efficient of friction" is extremely low. We know perfectly well that it depends upon many conditions that are difficult to maintain and to understand. Even the wisest admit that there is very little yet found out which throws a practical light upon that subject.

For instance, we know perfectly well when they decide the co-efficient of friction of paraffin oil, on two polished surfaces made to fit perfectly, we gain no light at all on what we need to use on bearings that do not fit equally well or have the same finish. If we are to decide how to construct a bearing, what its proportions should be, how large a sedgment it should cover, all of these researches would be directly in point. But if we have an engine that runs hot, or a certain construction of bearing that makes it difficult to find a suitable lubricant, these investigations afford us no light whatever, and I think that any engineer will agree with me that, crediting all possible value of researches regarding the co-efficient of friction, what we want to know is vastly beyond that.

For instance, an engineer comes to you and says: "I was using such a paraffin, and my engine ran cold; I am now using such a paraffin, and it runs hot." We find on examination that there is no practical difference between the two, but when we come to apply them to a bearing we find that for some strange reason the two oils do not work alike. When we apply them to spindles, we find that two paraffin oils often bear no relation to each other in their practical behaviour. We find that one will run at a much higher temperature, for some obscure reason. We might think it due to its viscosity, but we find by our instruments that it does not depend on that. In some instances, too, the results which we obtain are exceedingly contradictory.

The Rochester and Pittsburg Railroad Company run their cars with a bearing the surface of which is composed apparently of lead. There is a very thin film of lead—it appears to be lead—spread over the inner surface of the composition box, which looks as though it might be gun-metal. They say they will run an oil on this soft bearing that I know positively fails under similar circumstances, and on the same class of cars, on the Erie, New York Central, and Delaware and Lackawanna—just why, I cannot say for the life of me. I know that that shaft will sink down on that bearing, and yet it runs cold, and runs on a very cheap oil. One of the oil companies manufactures an oil which is composed largely of a mineral base which is united with a fatty acid. All things considered, that oil has been the most successful for running cold of any oil used on railways. And yet that fails to equal some other cheaper oils on the friction-testing machines. We have had occasion lately to make some comparative tests on fast-running spindles of the Sawyer pattern.

We have half a dozen oils from Europe, and several made in this country. Taking a spindle-frame, and adapting a dynamometer of my own, I expected to find that oils which had the best body would be the best oils for those spindles. I found I did not know anything about it. After having read many papers and listened to a great deal of talk from gentlemen who know a good deal about it, I found that the spindles did not bear out anything that I expected. Now, a spindle that was nicely fitted behaved in one way; but a spindle that was badly fitted behaved very differently. The effect of this was to establish a friction of its own in addition to the friction which we generally speak of as due to the oil itself. If we put on oil that has good body the heat increased very rapidly. Now, we should say at first that that was an objection to that oil. But we found after running them for a short time that the oils that gave us the best results in the economy of power were the ones that produced the most rapid wear. We found that after running constantly at some 6,500 revolutions a minute it had lost as much as $\frac{1}{6}$ of one gramme in actual weight. When we took another paraffin oil, the wear was not one-half of that, and there seems to be no apparent reason for it.

I have come to think lately that the question of wear on bearings, as ordinarily found, is one of vastly more importance than the cost of oil. One large mill owner came to me recently and said that he wanted an oil for his spindles. He said he did not care what it cost. He said: "After running some eleven mills for many years I have discovered that we sustain such great loss by wear due to poor lubrication as to make the mere price of the oil unimportant."

When the engines of the Brooklyn Bridge were started, the faulty construction of the bearings and journals caused rapid heating. I think it was generally believed by the engineers who examined them that the construction was faulty. The main bearings were like those drawn on the board, and the pinching on the sides appears to have been such as described. While watching those bearings quite intently one day, I happened to put my finger on the shaft (which I think measures 11in. in diameter) at a place where it showed extra pressure on the box, and I found it quite hot, while just $1\frac{1}{2}$in. from that section the shaft felt cold, showing how great and intense must be the heat generated when the conductivity of such a mass of iron failed to remove it. It seems to me that the conditions and behaviour of those journals corresponded with what Prof. Thurston has just described; and the binding in all such cases being simultaneous with an increase of temperature, I am led to wonder if it be not due to expansion by heat rather than to yield in the journal.

We generally find that where we can use oils of higher viscosity ordinary machinery bearings run colder. But in some instances of high speed and heavy pressure only thin oils answer at all, and the bearing must be flooded. I believe the engines of the Edison Electric Light Company, which run the dynamos in Pearl-street, are rated 75 horse-power, and run at the rate of 375 revolutions per minute. I am credibly informed that the oil they are using on these engines is the only sort yet found to run cold. This is an oil of about 32° Baume gravity, which is almost as light and fluid as common kerosene, and requires to be supplied constantly. I have come to think that this arranging of a steady current of thin oil is a very desirable plan wherever it can be practically carried out, as in the case of the Sawyer and Rabbeth spindles and nicely finished and fitted bearings of larger dimensions, like those in the machines these gentlemen have devised for testing oils.

With bearings nicely finished and journals carefully scraped and ground to fit, an abundant and constant supply of thin oil will give the best possible result in keeping the bearing cold and saving power. With such machines you may learn much of the proper proportions of bearings and of the conditions of friction in relation to pressure and speed, and of oils, too, under the exact conditions of these machines, but nothing of the requirements of machinery in common use. Why, these gentlemen think of a journal and bearing as two cylindrical surfaces in perfect contact. It would be more scientific and practical to regard the fit of ordinary bearings like that of a pea in a bushel basket. In many instances one point of contact would be almost too much to inspect, and the "body" or viscosity of the oil must make the fit. I know by my own observation that the results obtained in testing heavy lubricating oils on these machines do not correspond with the practical working of these oils on railway axles and other machinery, and any engineer to whom you might supply oils selected from such data would soon come back to you, as the saying is, "with tears in his fist and his eyes doubled up." We have been there—both sides.

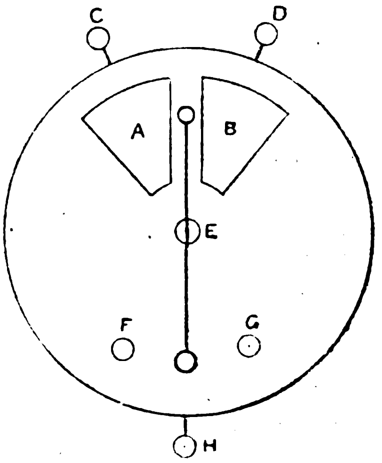
The fact is, the most important conditions under which these tests are made are the very ones that can only be maintained under special and unusual circumstances, and are never found in the great mass of machinery that must be lubricated. This makes the frictional tests by special machines worthless as a means of selecting lubricants, and a delusion to those whose opinions of oils are thus founded. I believe that the great value of these friction tests, and the machines by which they are made, lies in another direction; for we know that scientific research lies at the root of all industrial progress. But I think we must try an engine oil on an engine, a spindle oil on a spindle, and a waggon grease on a waggon, all as nearly as possible under the ordinary conditions, to learn anything of the real value of the lubricant.

While speaking of spindle oils, I should have added that I found their bearing parts did not wear bright. I considered their frosted look as indicative of a friction I saw no way of estimating, although it was attended with rapid wear. With oils of a higher viscosity and heavier gravity the bearing surfaces polish like a mirror, even though the friction, judging by the power consumed, is much greater with the more viscous oils. I infer that we cannot judge of the actual friction occasioned by the moving surfaces in contact, while we are unable to estimate separately that friction attributed to the oil itself. For using a thin oil we decrease that one friction so greatly that we cannot note any lesser increase in the other which occasions wear. If it be true that the question of wear is frequently of paramount importance in choosing special oils, then a low co-efficient of friction is no measure of value, and our frictional tests are worthless as a means of judging.

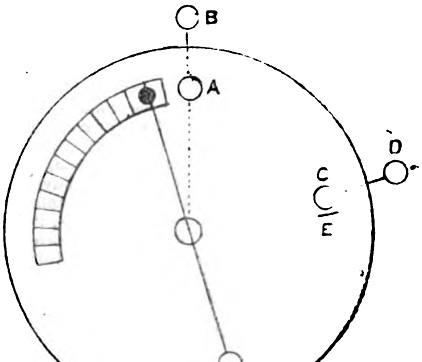
It is frequently said that we have petroleum oils which alone answer all requirements of lubrication. It is not so. I wish it was. I believe practical experience fully proves that in many instances compounded oils are best. Sometimes a thin petroleum oil, with a small portion of animal oil, gives better results. You may find instances where the best petroleum oils do not answer on an engine, when lard oil, or a mixture principally lard oil, keeps the engine cold and is every way satisfactory. This is sometimes the case whether the petroleum be of heavier or lighter gravity than the lard oil. But I am glad to say these are rare instances where petroleum oils do not answer every requirement.

## DR. MARSHALL WATTS'S ELECTROMETERS.

AT a recent meeting of the Physical Society two simple pieces of apparatus were exhibited by Dr. W. Marshall Watts. One of these instruments is a modification of the quadrant electrometer. It consists of a circular plate of ebonite, standing on feet, and covered by a glass shade. A small brass needle terminating in little brass balls is balanced on a point at the centre of the disc on an agate centre. The one end swings between two brass balls, F and G, standing up a short distance above the disc, and both connected with a ball, H, projecting from the under side of the disc. The other end of the needle moves over two plates of metal, A and B, severally connected with projecting knobs C and D. To use the instrument, a charge of known sign is communicated to the knob H, and the needle, after a few oscillations, comes to rest midway between F and G. The instrument is sufficiently delicate to give a decided deflection when C and D are connected with the plates of a small bichromate cell.



The second instrument may be regarded as a modification of Peltier's electrometer. It also consists of a disc of ebonite, having a needle point at its centre, on which turns a little needle, terminating in brass knobs; but the arms of this needle are of steel and magnetised, and the cap is metal and not agate. The directive force of the earth (or of a directing magnet, fixed on the cover of the instrument) may be made to bring one end of the needle in contact with the fixed knob A, which is in metallic connection both with the centre on which the needle turns and with a projecting knob B. When a charge is communicated to B the needle is repelled a greater or less distance, which is measured by a little graduated arc. The nature of the charge may be determined by turning the instrument round so as to bring the needle nearly into contact with a different knob at C, which is connected to a projecting knob D. The needle is prevented from coming into actual contact with C by a little ebonite stop E. If the charge is positive, the needle will then be repelled when a positively-charged body is brought near D, and if negative, then when a negatively-charged body is brought near D.



MESSRS. F. LEROY AND CO. ask us to state that they have ceased to have an office in Gateshead for the present, their agents there having left them. All orders or letters of business to be addressed to F. Leroy and Co., Gray-street, Commercial-road, London, E.

# SCIENTIFIC SOCIETIES.

## LIVERPOOL MICROSCOPICAL SOCIETY.

THE ordinary monthly meeting was held on Friday evening at the Royal Institution, the president, Mr. Chas. Botterill, F.R M.S, in the chair. Several donations of valuable slides were announced, and the thanks of the Society voted to the donors. The following ladies were elected members of the Society:—Miss Lucy E. Cradock, L K.Q C.P.I., and Miss Isabel Raleigh.

The Rev. H. H. Higgins, M.A., then made the following communication on natural vegetable mucus:—During the spring my study table has been plentifully supplied with terminal twigs of various trees and shrubs, set in water, to enable me to watch at leisure the expansion of the leaf-buds. Amongst them was the vigorous bud of a horse-chestnut, in which the gummy lacquering of the scales had set the storms of winter at defiance. Now, however, it was spring, and the bud was relaxing a little of its tight grip, whilst the bud scales were lengthening, and becoming leafy at their tips, showing that they were true leaves modified to serve a purpose. In the centre of the bud rose two little leaves, like green banners; but the petioles were flocculently woolly, after a fashion I had not noticed before. Many years ago I had found a small, bright orange fungus growing on a fallen log. The fungus was so slimy that it was difficult to take it up with the fingers, very much as an oyster out of its shell would be. A little of the transparent mucilage, magnified 400 diam., proved to be made up of monocellular trichomes, perfectly smooth and round, twisting and turning amongst each other like convoluted snakes, and forming the most perfect material for lubrication possible to be conceived. Part of the flocculent wool from the chestnut bud was collected, and, after having been wetted, was magnified. It was, as far as could be seen, identical with the mucilage from the fungus—a result which suggests that the mucilage had similar functions. When the bud expands, a forward thrust of the nascent leaves is associated with severe lateral pressure against the bud scales, causing a friction which, if the surfaces were naked, would be injurious. This very perfect lubricating material is provided by nature, and is probably found in many buds, though, when it has performed its office, the first shower washes it away. The mucus in the fungus has, I believe, been figured; though I am not aware that its function in the leaf-bud of the horse-chestnut has been noticed. Some have found a pleasure in fancying that recent science has eliminated teleology. To the theist the scope of teleology appears, on the contrary, to have become universal.

A paper was then read by Mr. Henry Kendall on "The Structure and Development of the Teeth." With the assistance of diagrams the three tissues composing the tooth were described. The dentine or ivory, traversed by numerous canaliculi, too small to admit of blood corpuscles; the enamel (the hardest substance in the human body), consisting of prismatic cells; and the *crusta petrosa*, which differs from true bone in having no haversian canals, except when hypertrophied by inflammation. In treating of the development of the teeth, it was noticed that, though they are classed with cartilaginous and osseous tissues as having conjunctive tissue for their basal substance, yet they do not form a part of the skeleton proper; they must rather be regarded as epidermic appendages, since they take their origin in papillæ formed on the *exterior* of the gums. Two methods of preparing dentary tissues for the microscope were then mentioned; the preferable one being to grind down the substance on stones of various degrees of fineness, and to polish the thin lamina thus obtained. The other process, less satisfactory, as destroying some of the characteristic features, consisting in dissolving out the calcary salts by means of acids, and cutting thin sections of the cartilaginous basis left undissolved.

## LIVERPOOL AND DISTRICT ASSOCIATION OF SCIENCE AND ART TEACHERS.

A MEETING of the Liverpool and District Association of Science and Art Teachers was held on Saturday in the Government School of Art, Mount-street, the president, Mr. Norman Tate, F.I.C., in the chair. After the reading of the minutes by Mr. Wm. Hewitt, B.Sc., hon. secretary, Mr. G. G. Tomlinson, Runcorn, was elected a member. The special committee appointed to consider a resolution moved at the last meeting by Mr. J. L. Barnes, in favour of the establishment of a museum of applied science, presented their report, which suggested an extension of the present Brown Museum by the addition of a "department of shipping and commerce," with exhibits illustrating different stages in the construction of ships, the machinery of vessels, and scientific appliances employed in navigating, lighting, and ventilating ships, together with signalling apparatus, lighthouse arrangements, life-saving apparatus, &c.; also specimens of articles imported into the country, with specimens, models, diagrams, &c., illustrating the processes of their manufacture and the practical application of their products, &c. The report was approved of, and the committee instructed to take steps towards the carrying out of the scheme. The chair was then taken by the vice-president, Mr. Edward Davies, F.I.C., F.C.S., while the president read a short paper on "The microscope as an aid in science teaching," in the course of which he referred to several important results that have already followed the use of the microscope in scientific research, the necessity of training science students in microscopical observation; the method of working which, in his opinion, was most suitable for such training, both in ordinary science classes and in laboratories of research. He laid much stress upon the reproduction of the microscopical pictures by drawing or micro-photography, and concluded by calling attention to several text-books on practical botany, botanical micro-chemistry, general biology, &c., which prescribed courses of study in which the microscope plays an important part. A short discussion ensued, in which Messrs. Davies and Marramore took part, after which much time was spent in the practical examination of microscopes, apparatus, and specimens exhibited by several of the members, and also a fine collection of slides forwarded by Messrs. Watson and Sons, of Holborn, London, and by Mr. B. Piffard, of Hemel Hempstead, and several students' microscopes and apparatus sent by Messrs. Thompson and Capper, and microscopes of various makers, and a Dallinger lamp and a lenticular prism, of his own make, from Mr. G. Wood, Lord-street, Liverpool.

# SCIENTIFIC NEWS.

THE following is the list of selected candidates recommended by the Council of the Royal Society for election to the Fellowship:—A. W. Baird, Major R.E., P. Herbert Carpenter, D.Sc., Sir Andrew Clark, M.D., Mr. A. A. Common, F.R.A.S., E. W. Creak, Staff-Commander R.N., Professor E. Divers, H. Hicks, M.D., W. M. Hicks, M.A., F. R. Japp, Ph.D., A. M. Marshall, M.D., Professor H. N. Martin, D.Sc., C. O'Sullivan, Professor J. Perry, Professor Sydney Ringer, and Sidney H. Vines, D.Sc.

The library of the Royal Society is in future to be open to Fellows, from 11 a.m. until 6 p.m., closing, however, on Saturdays at 1 p.m. In August and September the library will be closed at 4 p.m., but in July, hitherto a vacation month, the hours will be 11 to 6.

The Rev. T. E. Espin is about to publish, through Messrs. Swan Sonnenschein & Co., a series of star-maps, which will be called "The Beginner's Star Atlas."

The death is announced, at the age of 70, of Mr. William Ladd, F.R.A.S., a gentleman well known for the interest he took in the practical utilisation of many electrical inventions, and commercially as a maker of large induction coils, and the dynamo which bears his name. It was to Mr. Ladd that Reis sent his now historically famous letter describing the telephone, but the recipient does not appear to have apprehended the importance of the invention. Ladd's dynamo is well known to all science students, as it is figured in many of the text-books.

At the Royal Victoria Hall on the 12th inst. Mr. Dullinger is to lecture on "Wonderful Things we do not personally see," and on the 19th Prof. Perry will discourse on the "Spinning-tops of Japan and other countries."

A very useful railway guide and route books has been issued by the executive council of the International Inventions Exhibition. The book includes all places within a radius of about forty miles from London, and gives at a glance the number of trains daily, the times of the last, and indicates the station at which the change should be made, when that is necessary. It also gives the fares, including admission, and the average time occupied on the journey.

At a recent meeting of the Engineering Society at King's College Mr. R. B. Anderson, Stud. Inst. C.E., read a paper on "Heat in its Relation to Combustion," in which he referred to the terms used in connection with the subject. In reference to heat-units, he advocated the use of the "gram-degree," as it involved no confusion as to the thermometer scale and explained itself, but he deprecated the use of calorie, on account of the loose manner in which it is employed to represent the "gram-degree" and the "kilogram-degree." As a measure of heat, he thought it convenient to use the amount necessary to convert water at normal temperature into steam at any boiling point, which was discovered by Watt to be very nearly a constant quantity.

Mr. Stretton has issued (The *Train* offices, 280 Strand) his paper on the Leicester and Swannington Railway.

At a recent meeting of the Physical Society, a paper by Lord Rayleigh was read on "The Theory of Illumination in a Fog," which dealt with certain theoretical results based upon the assumption that the medium in which the fog is formed, and the substance composing the fog itself, are perfectly transparent. Under the title of a "Monochromatic Telescope," Lord Rayleigh also contributed a paper descriptive of a modification of Maxwell's colour-box. In this instrument light passes through a slit in the focus of a collimating lens; it traverses in succession this lens, a prism, and another lens by which it is brought to a focus upon a plane surface in which is a movable slit; the eye being placed behind which receives light approximately monochromatic. If in addition a lens be placed just behind the first slit, so as to bring some distant object into focus at a convenient distance from the eye, this object will be seen by the light that would enter the eye in the simple colour-box. Lord Rayleigh suggests the use of this instrument to compare lights of different colours, and the possibility of choosing some colour towards the middle of the spectrum at which lights might be compared for practical purposes.

The Geological Survey has issued a "memoir" descriptive of the highest and most picturesque part of the table-land of North-Eastern Yorkshire, a district composed mainly of Lias and Lower Middle Oolites, almost destitute of drift, and without signs of local glaciation. The higher ground probably formed an insular area during the Glacial period.

At a recent meeting of the Academy of Sciences of Paris some improved thermo-electric piles of Clamond and Charpentier pattern were exhibited. The couples are of iron or nickel and an alloy of antimony-zinc. One pile, consisting of twelve fsets o ten elements, exhibited an electromotive force of 8 volts and a resistance of 3·2 ohms; while another, half the size as regards number of elements, exhibited 3·6 volts and a resistance of ·65 ohm.

The Signal Engineering Co. are manufacturing an improved telephone receiver. They claim that by use of a specially designed machine for making the membrane diaphragm and other improvements in manufacture that they will work quite equal to the Bell telephone, not having the disagreeable metallic sound of the latter instrument.

At the meeting of the Leicester branch of the Amalgamated Society of Railway Servants, held last week, the debate on railway axles was closed, and a majority of the committee reported as follows:—(1) That iron axles are safer than steel axes; (2) that all cranks should have the webs hooped; (3) that as iron cranks appear to fail after running about 200,000 miles, and steel axles after 170,000, it is highly desirable that when they are known to have run these distances they should be taken out, carefully tested, and even if no flaw can be seen, they should not on any account again be used in passenger engines; (4) that crank axles properly constructed are as strong as straight axles.

In the *Lancet*, for May 2, Dr. A. de Wattville, B.Sc., has some further notes on the cure of writer's cramp, and gives in facsimile the handwriting in two cases before and after treatment by Mr. Wolff. The system adopted by the latter is a combined application of massage, gymnastics, and caligraphic exercises.

M. FLEITMANN, of Iserlohn, has shown that pure nickel and its alloys with copper, cobalt, and iron can have other metals added without their losing the property of being welded, and therefore can still be used for making plate. The metals which can be added in this way are zinc, tin, lead, cadmium, iron, and manganese up to as much as 10 per cent.; any additions, however, are not of much practical value, as the alloy of 25 parts of nickel with 75 of iron has a white colour, and resists the action of the atmosphere far better than the iron alone.

# LETTERS TO THE EDITOR.

*[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]*

*All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

*All Cheques and Post-office Orders to be made payable to* J. PASSMORE EDWARDS.

**** In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

> "I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks a vice from whence great inconveniences derive their original."

## THE SPECIAL MEETING OF THE ROYAL ASTRONOMICAL SOCIETY—SUNSPOTS AND RAIN—THE DIAMETER OF MARS—DEAN SWIFT AND THE MARTIAL SATELLITES—MOSSES—PHOTOGRAPHING THE SOLAR CORONA—THE HARVARD COLLEGE OBSERVATORY—ZETA HERCULIS—THE NEW TIME—CORRECTIONS FOR EQUAL ALTITUDES.

[24196.]—I HAVE received a circular from the Secretaries of the Royal Astronomical Society, to which, even at this eleventh hour, I would earnestly invite the attention of my brother Fellows of the Society. This official circular calls a special meeting on the night of the day on which these words will appear, to consider a proposition made under by-law 52, for alterations in two others—viz., by-laws 12 and 53 respectively: such alteration consisting in the addition to the former of the words, "Lists handed to the scrutineers of the ballot on behalf of any Fellow not present at the meeting, shall be accepted, if duly verified by the signature of the absent Fellow:" and to the latter of the words, "Fellows of the Society may vote on the business brought before annual general meetings and special general meetings, either personally or by proxy." Now, the obvious effect of these changes in our by-laws must be to enable every Fellow of the Society to exercise his personal influence, and to pronounce an opinion upon its management, whether he be resident in Chelsea, Caithness, Carrickfergus, or Candahar. We should thus secure a really representative Council, because Fellows resident at practically inaccessible distances from London would be able to vote for the men whom they considered the most fit to administer our affairs, without being dragged hundreds of miles to do so. Under existing conditions, an enormous majority of our Scotch and Irish Fellows, and the whole of our Continental ones and those serving abroad, are disfranchised. And if they have no voice in the selection of the gentlemen who so condescendingly rule over them, *a fortiori* they have less than none in the management of the Society. A Fellow may be, let us say, at Gibraltar, and may feel deeply interested in some question to be brought forward at the annual meeting. Leave, however, may be impossible to obtain, and the voyage too costly, if it were to be had; and so this man's hands are tied, while any single one of the Council is present to vote in precise opposition to his wishes and convictions. Let the man abroad, however, commit his proxy to some one whom he can trust at home, and his legitimate influence can be exercised at the meeting. Of course the select circle which dines at (and essays to direct the affairs of the Society from) Willis's Rooms, will fight tooth and nail against any alteration in a system which has made its members, so far, absolute autocrats, practically electing themselves year after year. Does any sane man believe that if the Fellows at large were in a position to exercise their franchise, the gross abuse of 25 per cent. of our Council consisting of the representatives of the Royal Observatory at Greenwich, could ever have been perpetrated? I do hope, then, earnestly and sincerely, that every Fellow of the Royal Astronomical Society, who has its independence and the best and truest interests of astronomy at heart, will, at any personal inconvenience, go to Burlington House to record his vote for the suggested changes. Depend upon it that the gentry who are quaking for their own seats at the Council Board, should any real election take place, will pack the room to the very utmost of their ability. Many a name of the hangers-on of the Brompton Ring will be inscribed in the attendance-book, which appears there but rarely indeed. There are certain faces familiar enough when any job is to be perpetrated, which are as strange as that of the Grand Llama of Thibet at our ordinary scientific meetings. Assuredly none of them will be absent. Will—or will not—Fellows anxious to restore the Society to its pristine purity of intention, play into these people's hands by absenting themselves?

From your report on page 166, it would seem that another nail was driven into the coffin of the sunspot humbug at the last meeting of the Meteorological Society, in the "Report of the Committee on Water Supply." As it is not so very long since a lecturer—who shall be nameless—so far presumed upon the ignorance of a working-class audience as to assure them that the greatest amount of rain was coincident with sun-spot maxima, and *vice-versâ*, it may not be uninstructive to compare the years of low water and of floods, as given by the Meteorological Society's Committee, with Wolf's table of sunspot phenomena. First, then, to take the years of drought:—1820 was three years, and 1821 two years before a sun-spot minimum; 1824 one year after minimum; 1835 two years after minimum; 1838, one year after a maximum; 1845, two years after minimum; 1847, one year before maximum; 1850, two years after maximum; 1854, one year before minimum; 1855, minimum; 1858, two years, and 1859, one year before maximum; 1864, three years, and 1865, two years before minimum; 1871, one year after maximum; 1875, five years after maximum; 1884, maximum. Now for the years of floods and high water: 1817, one year after maximum; 1825, two years after minimum; 1830, one year after maximum; 1836, one year before maximum; 1841, two years, and 1842, one year before minimum; 1853, two years before minimum; 1860, maximum; 1861, one year after maximum; 1866, one year before minimum; 1873, three years after maximum; 1878, minimum; 1881, three years, and 1883, one year before maximum. Let any candid and dispassionate reader study these figures, and say whether they shew that any connection whatever exists between sunspots and the quantity of rain which falls. And yet Messrs. Archibald and Co. were much shocked at the way in which I denounced that trumpery imposture, the "Solar Physical Observatory," which was *to* be established (at a cost of £*x*) to prove the dependence of one upon the other.

I doubt if a categorical answer can be given to the query with which Mr. Franks begins letter 24141 (p. 168). In the first place, the micrometrical measurement of the diameter of a planet with any very refined accuracy, is a monstrously difficult matter; and in the next a notable part of some of the metrical discordances which he tabulates has its origin in the fact that several of his authorities have employed the old solar parallax in their calculation. Sir John Herschel's figures, for example, must be diminished by one twenty-eighth part ("Outlines," page 695), and so with Arago and Mitchell's. Perhaps the best values of Mars's equatorial diameter that we at present possess are those of Schmidt, made in 1854 and 1856. He makes it 4358 6 miles: of Kaiser, who in 1864 determined the diameter to be 4256 miles: and of Engelmann, who, from measures taken during the opposition of 1873, found that Mars was 4210·4 miles in diameter at his equator. Presumably he is Webb's authority.

A good deal has been said about "Inspiration" recently in these colums; but if the fulfilment of an excessively unlikely prophecy can be (as it has been) accepted as evidence of it; then assuredly we can only regard "Gulliver's Travels" as an inspired work.

If Lovell, Reeve, and Co. still publish Stark's book on "British Mosses," Mr. Hitchcock (query 56429, p. 179) will find it the very thing he requires. He will get the "hints" he wants, as well as full and clear descriptions of all the species from it.

In a most interesting lecture delivered before the Royal Institution on February 20th, of which a reprint lies before me, that great astronomical physicist, Dr. Huggins, brings forward a considerable amount of evidence to substantiate the objective nature of the Solar Corona which he has from time to time photographed. I can hardly regard the assertion of his "friend, Mr. John Brett, A.R.A. . . . that he is able to see the Corona in a telescope of low power," however, as susceptible of inclusion among such evidence, inasmuch as it would seem to partake of that cock-and-bull character which has pre-eminently distinguished the specular reflection from Venus and cognate discoveries of the somewhat notorious observer referred to! At present, moreover, I fail to understand how any photograph of the Corona of the uneclipsed sun can possibly be obtained at all through the persistent glare of lighted haze which surrounds the sun on the very clearest days. I only know that I have utterly failed to detect Mercury at any time during the last two years. A strong point in favour of Dr. Huggins's contention is to be found in the fact that a peculiar rift which appears in one of his Coronæ photographed in May, 1883, is also visible in the negatives taken at Caroline Island at the same date during the total eclipse of the sun in that year.

From the annual report of Professor Pickering to the Visiting Committee of the Harvard College Observatory, I learn that that admirable institution worthily sustains its reputation, and continues its career of usefulness. Unfortunately, the period of temporary subscription by its friends towards the funds of the Observatory has come to an end, with the result that a reduction of its working expenses has become imperative. Its distinguished and disinterested director, however, is not the man to stand idly lamenting this, or to go whining to Congress to be "endowed" out of national funds. Perforce compelled to reduce his staff, he has manfully put his shoulder to the wheel, and there can be no doubt that his report for the current year will in no sense discredit an establishment which has heretofore maintained such eminence among the working observatories of the world.

As I, of course, never saw letter 24165, p. 187, until this (Friday) morning, the day for writing this latter half of my letter, I cannot possibly comply with "Beta's" request in time for next week's number. Burnham's own mean of his measures, by the way, in 1880·49 was 1·34″. The theoretical separating power of a 4in. object glass by Dawes's formula is 1·14″. My last volume (XL.) of the ENGLISH MECHANIC is, at this present writing, at the binder's, so I cannot refer to it; but I have an idea that some pretty recent measures of ζ Herculis were referred to in it. I may, perhaps, add that I pretty recently wholly failed to divide this star with a power of 260 on a 4¼in. Dallmeyer object-glass. I presume that it was not a bit of a diffraction-ring that your correspondent took for the *comes*?

With reference to letter 24192 (p. 193) I need only say that, as far as I am concerned, I advocate the change in the present method of reckoning time, because of the simplicity of the new mode, and the absolute immunity it affords of all confusion between a.m. and p.m. "Nun Dor." must bear in mind that, as far as astronomers are concerned, there is nothing new in it. A charming muddle we should be in truly if we tried to reckon Right Ascension in two divisions of 12 hours each! Moreover, your excellent correspondent must forgive me if I say that I am seriously puzzled "in connection with the times" on the greater main lines in "Bradshaw"; and that here I err in good company, inasmuch as the immortal discoverer of the planet Neptune has recorded how he once went down to the station at Cambridge to meet a train 12 hours after it was due! As for the crazes about decimalising our divisions of time, they stand upon an absolutely different footing, and involve an amount of learning—and unlearning—which must form an insuperable barrier in the way of their general adoption. Simply reckoning round 24 hours, however, stands, I venture to think, on entirely different ground; in fact, from long observational experience, I am convinced that a fortnight would familiarise everybody with it. Assuredly, when it was once introduced and folk had got used to it, they would wonder how they could have tolerated the cumbrousness and inartistic character of the existing method of dividing the natural day.

I fail to see how "X. N. X." (query 56466, p. 200) obtains his data. For instance, the mean of his clock times (the T of the formula)

$$\frac{10\text{h. } 33\text{m. } 14\text{s.} + 13\text{h. } 27\text{m. } 20\text{s.}}{2} = 12\text{h. } 0\text{m. } 17\text{s.},$$

and not 12h. 0m. 45s., as he has it. So, again, with his $\theta$ (the increase of N.P.D). It is true that the *hourly* increase is only 57·96″; but in 1h. 27m. 3s. this amounts to 1′ 24 09″, the quantity he must employ; so that his $\frac{t\,\theta}{15}$ will become $\frac{84\ 09''}{15}$, or 5 6. The true additive correction is 19·803s. to the mean of his two observations: i.e., 0h. 0m. 17s. + 19·8s. = 0h. 0m. 36 8s. as the observed time of apparent Noon. The working of the example seems somewhat cumbrous, too.

## JUPITER.

[24197.]—I HAVE just come in from observing Jupiter with my 8in. reflector, and was able distinctly to recognise the transit of Satellite III. as a dark body across the disc of the planet. The satellite was immersed in the dusky northern belt, but it was nearly as dark as the shadow would have been. I watched it from 10 to 10.30 p.m., when the planet was obscured by clouds. I was able to trace the movement of the satellite from about the central meridian to nearly half-way to the western edge of the planet. I think there will be no other favourable opportunity for witnessing this phenomenon this season. There is a transit of this satellite on the 9th at 11.56 p.m.; but the planet will then be too low for observation.

I shall be glad to know if this observation is confirmed by others, and find some explanation of the phenomenon offered. I used a Browning achromatic eyepiece magnifying 144, of excellent definition. John Bone.

St. Thomas' Vicarage, Lancaster, May 2.

## JUPITER'S SATELLITES PARTIALLY OCCULTING THEIR SHADOWS.

[24198.]—THESE phenomena are not as rare as might be imagined, and many instances would soon be recorded if observers looked for them when Jupiter is near opposition. Besides the observation made by Dr. Knobel in 1872 (referred to at the last meeting of the R.A.S.), several others have been published from time to time. There is one in the ENGLISH MECHANIC, Vol. XXIII. p. 562, by Mr. G. D. Hirst, of Sydney, N.S.W., accompanied by a sketch showing the shadow of the 1st Satellite, on May, 1876, as a dark crescent breaking away from the west side of the satellite, and situated in the bright zone N. of the equatorial belts.

The recent partial obscuration of the shadow of the 1st Satellite on Feb. 18th, 1885, was casually observed here while awaiting the transit of the red spot on Jupiter, which occurred at 12h. 4m. The air was far from good; but the shadow was glimpsed as a dark crescent, exceeding a semicircle, and evidently obtruding from the W. side of the satellite, or rather, to be more accurate, from the S.W. side, for at times, when definition became tolerable, the breadth of the shadow seemed more above, and S. of the satellite.

On April 18th, 1885, at 7.37, I saw Sat. IV. skirting the N. rim of the great N. equatorial belt, as a dark brown spot. I also observed this satellite in transit on Jan. 8th, 1885, at about 15h., and on Feb. 27th, 1885, at about 13h. 25m.; but I have not seen the satellite as an intensely black spot, such as described by Mr. Spitta in the *Monthly Notices* for March, 1885, p. 344. I particularly noticed, on the early morning of Feb. 28th, when both satellite and shadow where projected on Jupiter, the unmistakably deeper tone of the shadow. Relatively to the extremely bright central regions of the planet, this satellite appears very dark indeed; but when the shadow is also present, affording the means of comparison, it is seen at once that the satellite is not absolutely black.

Bristol, April 30th. **W. F. Denning.**

## DOUBLE STARS.

[24199.]—Mr. SADLER hardly recognises the effect of his own eminence in letter 24166. I apologise if I overstated his remarks upon my supposed observation of Hyperion; but the astronomical world would look upon his statements as amounting to deciding the question against me, and I so accepted it.

With regard to his references to θ Aurigæ in "E. M." for Feb. and March, 1883, my only excuse is gross carelessness. Having come across some notices of the star in a back volume, which only had to do with mag. of θ itself, I, without looking up the references, concluded these were what Mr. Sadler meant.

I take it, the *comes* must be variable to a considerable extent, and is also closer to the large star than the distance given in "Celestial Objects."

Allow me to thank Mr. Millar (24106) for his replies *re* Spectroscope.

With regard to $a^2$ Cancri, I have the fourth edition of "Celestial Objects," and cannot find any reference to $a^2$—$a$ is in the Appendix 1, but not $a^2$. Possibly the small 2 has failed to make an impression in this copy.

Will Mr. Sadler tell me present position angles and distance of γ Leonis? I ask because, after careful measuring, I cannot make the P. A. much other than 100°, and as according to Webb, the motion is in direction of increasing position angles, and the latest measure is given as 112° in 1877, I do not see how to reconcile the measures. I tried it three times. Have I made a stupid blunder? Is there any suspicion of motion in Cor Caroli, and what is the date of measure of 54 Leonis, as given in Webb? I make this 88° or 89° now; but the weather continues so bad it is difficult to see any star long enough to get a measure.

**Edwin Holmes.**

## A CHEAP AND EASILY-CONSTRUCTED TELESCOPE STAND.

[24200.]—I SEE that in the engraving of telescope and stand on page 189, the engraver has neglected to connect the bottom of the telescope to the tube that carries it. The strap on the telescope is shown, but not attached to the tube, so that it appears as if carried only by the two straps near the middle of the telescope. The weight also near the part under the double or fast-and-loose lever, which draws the telescope after the star, is not shown. **Philip Vallance.**

## SMALL REFRACTORS AND TESTS.

[24201.]—ON Saturday, May 2nd, having read "Beta's" letter (24165), I tried my 4in. Cooke, focus 59in., on ζ Herculis, but should not have known that it was a double star with a power of 283, as its disc appeared quite round.

That evening was very steady, to which I attribute my success in seeing, for the first time, the *comes* to δ Cygni; power 288. I did not previously know the position of the comes; but after I had seen it, I checked the observation by a reference to Prebendary Webb's book.

It was a very difficult object, as the *comes* was cut through by the first diffraction ring.

I should have liked to have tried a higher power, but have not got one.

I observed the following with the 4in. Cooke:—

ι Leonis, power 70 (very well seen), *a* Lyræ, with aperture reduced to 2in., power 70 (very difficult).

ε Lyræ, Debilissimæ, full aperture, power 140 (seen immediately); Castor, power 27½ (my lowest power).

Also the following with dumpy 3in. Dallmeyer, focus 27¾in.

ι Leonis power 80 (well seen).

ξ Ursæ Majoris, power 130 (discs in contact, notch quite sharp); Castor, power 33½.

*a* Lyræ, power 46½, aperture reduced to 2in. (*comes* held steadily).

Ditto, aperture reduced to 2in. (*comes* glimpsed many times).

Would "A Fellow of the Royal Astronomical Society" kindly help me in the following difficulty?

I can see $\epsilon^1$ and $\epsilon^2$ Lyræ with my naked eye; without difficulty; distance 207". With the telescope, Castor, as above, distance 151" with 4in. Cooke, and 184" with 3in. Dallmeyer; but ξ Ursæ Maj., taking Mr. H. Sadler's distance (24166) requires, with 3in. Dall., 234". With this glass also I have frequently seen Polaris with a power of 18½; but that equals a distance of 346". ι Leonis, with the 4in. a distance of 203"; and with the 3in., a distance of 234". My difficulty is this: If you can see with the naked eye stars at a distance of 207", why should not everything else be visible with the same distance?

In other words, why did not the 3in. Dall., which showed Castor with a distance of 184", show ξ Ursæ Maj. with a similar distance? The fact being that the stars, *although quite sharply defined*, were in contact, with a distance of 234". Polaris, too, requires a distance of 346"; according to Castor, it ought to be seen with a power of 10; and according to $\epsilon^1$ and $\epsilon^2$ Lyræ, by naked eye, a power of 12; but I have tried it over and over again with a power of 13 and have not been able to see the companion.

Would it not be possible to construct a formula by which the following problems might be solved?

If a certain telescope will show a pair of 4 and 6 mag., dist. 8", with a minimum power of 22½, what is the least power the same telescope will take to show a pair 4 and 6 mag., dist. 2"? It is understood, of course, that the star mags. and distances are within the theoretical grip of the instrument.

A more complicated formula might solve the following question. With the same data, what power would the same telescope take to show a pair 3 and 9 mag., dist. 3"?

**Edward M. Nelson.**

## EVOLUTION.

[24202.]—WILL someone kindly answer the following?—not sending me to a library, to which in the country there is no access, nor to books, for the purchase of which I have no money. What reason is there to suppose that a fossil creature, half-bird and half-lizard, or other recognised intermediate link, is so in reality? Why should it not have been purposely created in that form? Suppose the seal to die out of existence, it would, I presume, be called a link between mammal and fish; ditto a whale, but in any case, why should it be considered that these were not always as now—viz., distinct creations? There was once a *bird* with a full row of teeth. I make it a link certainly by saying I do not know what the *beast* is called; but I see no reason why the *creature* should not have been so made, and I want those who do see this to open my eyes and let me see it too, if it is indeed visible.

Then again, is it not said that any special organ not used gradually decreases in size, until after many ages it becomes lost, a limb leaving a mere knot perhaps to show where it used to be. But why should any living creature cease to use such limb, and his or its descendants continue the same disuse? A parrot uses its beak in climbing, and it is a big beak and a strong one, as can be discovered by insertion of a finger. If it ceased to use it, it might grow less; but why should some insane parrot try to climb without using his beak, and teach its progeny the same difficult art? These things are mighty puzzles to **Pre-Adamite.**

## MICROSCOPICAL STAINING—MOUNTING BACTERIA.

[24203.]—As a supplement to the introductory method of sputum-mounting described by "B.Sc., Plymouth," perhaps I may be permitted to describe some other methods, with reference to sputum in particular, but also with reference to "bacteria," as they are often called, or Schizomycetes generally. (1) Cause sputum expectorated first thing in the morning to be spat into a *clean*, covered vessel, without admixture with water or with any disinfectant. The expectorated matter will consist of masses of sputum of a bluish, greenish, yellowish; or, if the sputum contains blood, reddish colour, and more or less tenacious. For the tubercle bacillus the less tenacious sputum, in the last stage of consumption, but not just before death, is the best; for the thicker sputum will probably have lain in the upper part of the windpipe before being expectorated, and before death there is a difficulty in bringing it up from the lungs. That which belongs to the same mass as a streak of blood is likely to be good. Mixed with the sputum there will be saliva, and, if the coughing has caused sickness, matters from the stomach. (2) Proceed with the subsequent processes without needless delay. Take out a little with an old teaspoon or saltspoon, which is never again to be used for its original purpose, and lay this on a sheet of newspaper or other paper, on which the whole of the appliances used should lie. (This is for the sake of cleanliness and safety; the paper must be burnt as soon as the operation is finished. The sputum most likely to be examined is that of suspected consumption, and may not improbably contain the *Bacillus tuberculosis*, the germ of consumption, scrofula, etc. It is, therefore, not a thing to play with). With the point of a scalpel, helped by an ordinary sewing needle mounted in an old penholder, transfer a little of the sputum to the centre of a ⅝in. or ¾in. No. 1 covering glass. (The scalpel, needle, forceps, scissors, slide, and whatever else has touched the sputum should be wiped with paper to be immediately burnt in the chimney, and then immersed in carbolic acid and water [one in thirty], after which they should be wiped; and, finally, thoroughly heated in a flame. The aim of this is to help to preclude possible infection. The first wiping will remove the bulk of the possibly infectious sputum. The steeping in carbolic acid and water will help to kill the germs, or, at least, to maim them. The burning in the flame may be trusted to kill them, and does not injure the instruments as much as might be expected. The flame should be that of a spirit-lamp or a Bunsen burner, since it is smokeless, and the instruments should be moved about in it to prevent all the heat falling in one place. It is well to have a scalpel, a pair of scissors, a few mounting needles, and a couple of pairs of forceps—one for taking up the sputum if needful, and the other for moving the covers from place to place—which are antiquated for other purposes, as one would not care to spoil new and good instruments by heating them almost to redness in a flame. The heat, or the carbolic acid and water, need not, of course, be applied to those parts which have not touched the sputum. Neither the sputum itself, nor anything which has touched it, ought to come in contact with the hands, which ought to be afterwards washed with Calvert's carbolic soap. If the sputum is suspected to be specially dangerous—if, for example, it is believed that the case may be one of diphtheria—remember that corrosive sublimate ($HgCl_2$, bichloride of mercury) is a much more powerful disinfectant than carbolic acid. Keep on the windward side of the material worked on. Do not leave it about, but finish it up at once, and then pour carbolic acid and water or bichloride of mercury solution (1 p.c.) over it. Take care of cuts and scratches—even the most minute—on the hands, and be careful not to be pricked by the needles, &c. Impregnate the air with chlorine where there is any suspicion of special infectiousness. This may easily be done by chloride of lime and hydrochloric acid and water; it cannot be trusted to kill germs, but helps to maim them. (I have to apologise for the length to which these remarks, thrown in between brackets, make this communication run; but they may save someone's life). If the sputum is tenacious, some of it may be taken up with a pair of blunt-edged forceps, and a string of about the size of a large pin's head snipped off with a pair of fine scissors. (It is convenient to have the cover, to which the sputum is transferred, on the corner of a slide, over which part of its edge projects a little—1-32nd of an inch. There is then something to lay hold of it by in removing it. For the same reason, when one cover is laid upon another, as presently to be described, they should not be laid quite edge to edge, or so as exactly to coincide, or it may be impossible to separate them. To lay the cover on a slide secures it a flat suface to rest on, and prevents breakage. Besides, it is cleanly, as the slide may, after use, be wiped, and immersed in carbolic acid and water as previously described. In dealing with very infectious matter, it is well to dispense with all wipings, and to transfer what has been used to a large vessel of solution of bichloride of mercury. If a piece of white paper is put beneath the slide, the light will shine up, and everything will be more visible). If, on the other hand, the sputum is very fluid, it may be taken up by dipping a glass rod into it, and thus transferring to the covering glass. Or a pipette may be used. (If there is plenty of material, it would be well, in the first instance, to try the effect of working on sputum mixed with carbolic acid or mercury solution. The risk would thus be diminished; and though the stains act sluggishly when this is done, they, as a rule, act in the long run). (3) Take another cover, and lay it on the former one, but not quite edge to edge. Press it down with a mounted needle so as to make the sputum spread, and, for the same reason, move it a little to and fro. A dozen trials will show how to diffuse a thin and delicate film over the cover. Then slide the upper cover off, pushing it to one side by applying the needle to its edge. If the needle has a little curve at its extremity, so much the better; and the film finally left will be the thicker the more obtuse the angle at which the needle is placed to the surface of the cover. More pressure has, of course, to be used for thick than for thin sputum; but the whole operation need not take more than a minute, and a few trials will teach the details. (4) Lay the covers aside out of the dust to dry quickly. They may be placed on a piece of paper under an old butter-dish cover, bell-jar, &c., and will, of course, dry more rapidly if accompanied by a little chloride of calcium in a watch glass, tooth-paste pot top, or other small receptacle. When dry, pass them quickly three or four times through a spirit-lamp flame—which has the effect of fixing the film to the glass—taking care not to use so much heat as will brown the film. This burning process seems, I admit, a barbarous one. However, the film may equally be fixed by hyperosmic acid vapour (make a 1 p.c. solution of hyperosmic acid, and put a little in a watch-glass along with the drying covers), by alcohol vapour, and also in other ways. Hyperosmic acid, first hardens, and then stains: it has quite done the first when the slightest possible brown tinge is observable on the film. Other stains will scarcely take after prolonged exposure to it. The vapour is said to be dangerous to life, and must not be breathed. Next, as to the staining of the film. This may be effected in various ways:—(1) By the ordinary old-established vegetable stains—carmine or logwood—to show the blood-corpuscles and other large cells contained in the sputum; (2) with metallic stains, as hyperosmic acid, silver, gold, &c., which stain both these and the germs; or (3) by aniline methylene dyes, &c., with the specific object of showing the germs, or some particular kind of them. (1) To stain with carmine or logwood, I tease out the sputum with needles, and, before it has become dry, float the cover with the sputum side downwards on the staining fluid. If this is gently done the film does not come off. In a series of articles in the "E.M." on Microscopic Mounting, I have described the subsequent stages of the process. They may in this case be wet mounted. (2) To stain with hyperosmic acid, all that is needed is to allow the acid to act longer and more vigorously—e.g., by floating the covers after they have been exposed to the vapour in the 1 p.c. solution, with the sputum side downward. Micrococci thus stain readily. Silver is sharper and more discriminating. Make a 10 p.c. solution of pure crystallised nitrate of silver, with a drop or two of nitric acid, and add to a little of it, which is immediately to be used for staining, as much *liquor ammoniæ* as just suffices to redissolve the precipitate at first formed—a thing to be attended to, as the alkali tends to unfix the film. Float the cover on this; do not let it sink, or the preparation will very likely be messed by a finely-granular precipitate which forms. Terchloride of gold may be used in an analogous way; and the preparation may afterwards be stained with other dyes; but these processes are more suitable to cultivations than to sputum. (3). Combinations of aniline, &c., dyes are specially used to bring out the germs. As to these stains (*a*) for the common bacillus of sputum, the *Bacillus tuberculosis*, (*b*) for this and other bacilli or micrococci, or (*c*) for whatever is in the sputum, may be desiderated. For the Bacillus tuberculosis Heneage Gibbes's method is the best, and is as follows:—1. Take a given quantity—say a fluid drachm and a half—of aniline or aniline oil. This is a clear fluid, with a smell like that of gas, but sweetish; it dissolves slightly in water, but is apparently miscible in any proportions with alcohol. Dissolve it in six times its bulk (nine fluid drachms) of absolute alcohol, or in nearly seven times its bulk (ten fluid drachms) of good rectified spirits of wine to which a little alcohol has been added. Procure also some magenta, say, ½oz. Magenta is acetate, or hydrochlorate, of rosaniline, and there are, I am informed, about two dozen kinds of it in the market, passing by various names and prepared in different ways. It is a green, non-deliquescent, semicrystalline substance, in lumps, with a metallic lustre, dissolving in water, spirit, or acetic acid, without sediment, and forming a red solution. All the kinds are not equally proper: it is safest to procure it from Hopkins and Williams, through the local chemist, at the same time asking that it be stated that the dye is wanted for tubercle bacilli. In this way a definite substance will be procured; and this is of the greatest importance on account of the multitudinous varieties of aniline dyes, magenta-coloured and otherwise, which have been introduced for commercial purposes. With a vague magenta, methylene blue, or whatever it may be, procured anywhere, one does not know what one is using or what to expect. Weigh out two-thirds of a part (i.e., a drachm) of this and transfer it, e.g., to an ounce measure glass, having at hand a 4oz. stoppered bottle for the reception of the stain. Pour on it a little of the spirit with the aniline, rub up the crystals with a glass rod (which is easily made from a bit of tubing), and pour off into the bottle the deep red-coloured liquid. Treat the sediment with more of the spirit and aniline, and so on till the whole is used up. Then measure out ten fluid drachms of distilled water, if rectified spirit was made use of, or a proportionately larger quantity if absolute alcohol was employed; rinse out the measure glass with it, and pour it into the bottle little by little, shaking as you pour. Label "Heneage Gibbes' Magenta Stain." It is a very deep and strong stain, and should it touch the fingers, the colour may be removed by sulphuric acid and water. (2) To use it, pour a little into a tooth-paste pot top, or some such thing, either floating the covers on it film side downwards, or arranging them on the bottom film side upwards and dropping the liquid over them; the first course being most cleanly, and the second most efficacious. To prevent evaporation, cover the whole up with a glass circle, smearing the edges of the pot top with vaseline or vaseline and paraffin. Leave the covers to stain for six hours or more, in a warm place; and before taking them out, let them be heated to between 90° and 100°. If the heat is much more than this, the magenta will blacken; if it is much less, the bacilli cannot be trusted to stain. The bacilli of tuberculosis and also those of leprosy have this peculiarity, that stains find an exceptional difficulty in getting into them—a difficulty, however, which may be overcome by the use of aniline as above, or by that of carbolic acid or of several other substances; and, once in, they also have a difficulty in getting out. The next point, then, is to wash the magenta out of the other constituents of the sputum without removing them from the tubercle bacilli; and this may be done by the use of any strongish acid (picric, formic, oxalic, &c.), of which nitric is usually preferred. The acid has, of course, again to be washed out, and this is done with *distilled* water. Consequently (3), take up cover by the edge with a forceps, and wave it once or twice in ordinary water. This to take off the thick of the stain and to spare the acid. Then with a tube brought to a narrow end, but not to a capillary point, take up a few drops of nitric acid and water (commercial nitric acid, a fluid drachm and a half, filled up to six fluid drachms with *distilled* water), and drop a little on the wrong side of the cover, i.e., on that on which the film is not. This will clear away from that side any stain which may have got on it, which would otherwise prevent the process of decoloration being followed; for in all spirit solutions the covers are apt to sink in the staining fluid, even though they should originally have been laid evenly on the top. Then drop the acid on the right side of the cover till the red has disappeared. Then with another tube drop on distilled water till the acid is presumably quite washed away; proceed to the next cover, and so on till the whole are finished. Of course the covers must be held over a separate vessel, for if the droppings fell into the acid it would become full of magenta, and if those from the washing away of the acid fell into the distilled water, it would become acidulous. When the distilled water is applied, a slight redness will reappear. This is of no consequence; it is, indeed, inevitable when there are many tubercle bacilli in the sputum; and if the washing is carried too far, it will take the colour out of the tubercle bacilli as well as out of everything else. But if the red is at all pronounced—if it is more than a slight pinkness—return and use a little more acid, for it is then probable that the magenta is not entirely removed from the other constituents of the sputum. (4) Make, say, 2oz. of a saturated solution of methylene blue in distilled water—i.e., add the blue till some of it remains permanently undissolved at the bottom; put in a crystal or two of thymol to prevent mouldiness. It is well to do this with all aqueous non-mineral staining fluids. There is the same difficulty with methylene blue as with magenta; I get mine from Hopkins and Williams. I *believe* what is called BBBBB methylene blue is the best. Leave the covers in or on a little of this for not less than five minutes. If they are laid on the bottom, a little dot of vaseline applied to the under side of each cover will prevent them from rising when the fluid is gently poured in. In all these operations it is needful to remember on which side the film is, and not to let the cover drop any distance, as it would then turn over and over. It is well, therefore, to hold the covers, in washing, quite close over shallow vessels, and to get into the way of holding them in the forceps in a determinate manner—e.g., with the film toward the thumb. But should the right side be forgotten, scratching the surface near the edge with a needle will show which it is. These may seem very minute details; but it is by such little things that one is chiefly puzzled when one is working by oneself. Besides, the same points occur in dealing with other Schizomycetes. (5) Take up the covers one by one (lifting them up gently with the forceps if they are floating, or sucking up the fluid with a tube or a syringe if they are lying at the bottom), and wash them with distilled water, as described above, for taking out the acid, till the water comes off very slightly tinted. Drain off the water by putting the cover on its edge on a bit of blotting-paper, preferably damped, or by rolling it on its edge like a wheel on the back of the hand. Then put it for two or three minutes into absolute alcohol (in a tooth-paste pot, paint-dish, watch-glass, &c.). Drain off the alcohol in like manner, and place the cover under a bell glass to dry. If the blue of the first cover tried washes out too much by the distilled water and alcohol, return it for a while to the stain. (6) Supposing the covers duly stained, the mounting had better not be delayed, so as to avoid action of the air on the film. Take some Canada balsam, say, ½oz. by guess, and heat it in an evaporating dish on a sandbath over a Bunsen burner, or in some equivalent way. Vapours will be given off, which must not be allowed to come in contact with a flame, and the balsam must not be permitted to do more than simmer. It must be watched, and when it has begun to give off a thick, white smoke, and is on the point of turning brown—it will then be tenacious in spite of the heat—pour it, when cooling, into a wide-mouthed stoppered bottle previously heated to prevent cracking, and let it become cold. A safer but more tedious plan is to let it harden gradually in a warm place; in either case it must be protected from the dust. Procure some xylol (a limpid, colourless, fragrant, very volatile liquid), say, 1oz., in a stoppered bottle, and add to the Canada balsam (which will be a dry mass like hard resin) as much of this as nearly suffices to bring it to its original bulk; and with time and occasional agitation the balsam will be redissolved. The mounting fluid thus prepared has the advantages of drying very rapidly and not causing the stains to fade to any appreciable extent. It should be about of the consistency of sweet oil, and to thin it down to this it may be necessary to add a little more xylol, the exact amount depending on the thickness or fluidity of the original Canada balsam. The xylol must contain no water. A mixture of ether (*Æther methylatum lotum* or *Æther lotum*) may be used instead. (7) The mounting itself is very simply accomplished: by placing a small drop of this fluid on the centre of the cover, applying it to an ordinary, but thin, glass slip, and persuading the superfluous balsam to depart by pressure with a spring clip. By this method of staining the tubercle bacilli show out red on a blue ground, looking like little red worms. Sometimes other red particles make their appearance; but they have not the shape of the bacilli, and the method is a perfectly trustworthy one, though a failure or two must be expected at first in the course of overcoming the initial difficulties of manipulation. The bacilli will not fail to be shown, *if* they are present. But they may *not* be present, even if the sputum is from a consumptive person; for even if the lump of sputum contains them, there may not have chanced to be any in the particle mounted on a given slide, and the sputum of a consumptive person will contain them only if it has come from an ulcer or cavity where they were actually being set free, and not if it proceeds merely from some region where mucus was being poured out on account of inflammation of the chest. When, on account of irritation in the chest, whether produced by a cold, by bronchitis, by tubercular consumption, or in any other way, the air tubes contain an exceptional quantity of viscid fluid; it is to be expected, and it is the fact, that it will contain other organisms besides tubercle bacilli. These other organisms—micrococci, bacteria, and bacilli of various kinds, enter with the breath, fall on the viscid matter and into the cells or cavities of the lungs, and, not being expelled at once on account of the passages being clogged, live and cultivate there, and come away with the sputum. They will very likely show blue by the above method; but the stain may be washed out by them, so that they may be faint and inconspicuous; and a better way of demonstrating them is by the use of Gram's double stain (which contrasts them with the non-schizomycetous constituents of the sputum) as follows:—Make saturated solutions of gentian violet in alcohol, and of aniline (i.e., the oil itself) in water; and for use mix a little of the first with nine times as much of the second. Place the covers on this for a few minutes; it will stain them violet. Dissolve twenty grains of iodide of potassium in fifty fluid drachms (rather more than four fluid ounces) of distilled water; and after dipping the covers in water so as to get rid of floating purple stain, wash them with and immerse them in this second fluid, which, in a minute or two, will take the colour out of everything but the air organisms mentioned above. Place them next (after a dip in water as before) in absolute alcohol, which completes the decoloration. Make a saturated watery solution of Vesuvin, or of Bismarck brown (boiling, in distilled water), and in this place the covers till they receive the stain, which they will very speedily do. Place in absolute alcohol to remove surplus stain, and mount as above. The air germs will be stained bluish-purple, and the other constituents of the sputum yellowish-brown — except the tubercle bacilli, which will be invisible, or almost so, not being stained at all. But they come out with great distinctness of detail if the first fluid is used as indicated for the magenta fluid described above, though they cannot then be distinguished by their colour, as they receive the same purple as the other bacilli, &c. If, however, the magenta is used first, and, after the covers have been washed with acid rather less vigorously than usual, the Gram purple is used for a few minutes, the *B. tuberculosis* comes out red and the others purple; but the contrast is not a good one. And, finally, if the Gram purple is lightly used, or the iodine and subsequent brown stain well applied, some bacteria, &c., come out purple, and others yellowish-brown. The sputum, however, had to pass through the mouth, and thus there will probably be in it, or, at least, in the saliva surrounding it, other organisms from the mouth or teeth. These may be examined separately by spreading a little saliva, not containing sputum, on a cover, as above, and staining. Saliva and other thin fluids may also be spread by a mounted needle held close to and parallel with the face of the cover; and greasiness of the covers may be got rid of by the use of *liquor potassæ* and water to wash them with before using. The best saliva is that procured in the morning after waking, before cleaning the mouth. The contained micrococci, bacteria, &c., may be stained *red*, with the magenta solution diluted and not afterwards washed out with water; *blue*, with the methylene blue solution; *purple*, by the first fluid of the Gram, without using the second; or *yellow* or *yellowish-brown*, by the Vesuvin or the Bismarck brown solutions. There is thus choice of stains; and which is to be taken is a matter chiefly of convenience, taste, and familiarity. The disadvantage of magenta is its liability to fade, which exceeds that of these dyes as a whole; but they are less likely to become bleached the smaller the amount of organic matter—very small in these organisms—with which they are conjoined, especially if kept in the dark. They last worst in wet mountings, and in imperfectly hardened objects—for micrococci, &c., *may* be mounted in glycerine or glycerine and water, which shows up their envelopes well. If it is desired to stain *red* with magenta, it is advisable to use a fluid more easily prepared than that given above—e.g., (1) Magenta five parts, dissolved in rectified spirit 100 parts, to which 100 parts of distilled water are added; (2) magenta in acetic acid and water (acid "fuchsin," as this stain is also called fuchsin in Germany, from its fuchsia-like colour); (3) saturated alcoholic solution of magenta one part, saturated watery solution of aniline nine parts (this may also be used for tubercle bacilli). Magenta, on account of its rapid action, is chiefly employed for staining for immediate examination. For more bulky objects than bacteria, a weaker solution may be employed, made by diluting any of the above with water, or (4) magenta one part, distilled water 1,600 parts; add 10 parts alcohol. Many metallic salts—e.g., corrosive sublimate—curdle magenta, and other aniline dyes. Methylene *blue* is, in many ways, a very remarkable stain, and shows up well the interior details of many of these minute organisms, as the spores. Of *purples*, aniline purple, dahlia, and Spiller's purple, have been employed as well as gentian violet, and an excellent purple, methylene violet, which is the basis of the French purple inks, does not seem so well known in this country as it deserves to be, and is very durable. Saturated alcoholic solution of methylene violet one part, water nine parts, wash with one per cent. solution of acetic acid, and dip for a moment in alcohol. For *yellow*, iodine may also be employed, both for immediate examination, and if the objects are to be mounted in glycerine. (1) A saturated solution of iodide of potassium in water, saturated with iodine; (2) a saturated solution of chloride of zinc in water, also saturated with iodine; or (3) tincture of iodine, strengthened if need be. The first will need to be diluted with water (Lugol's solution); the second can be used only for immediate examination; and the third will sometimes work when neither of the others will do so. The other constituents of sputum are (1) Mucus—filmy streaks, faintly stained. (2) Debris of food from the mouth, and, in cases of lung disease, of debris from the lung. These may be of different kind, and I cannot attempt to enumerate them. (3) Epithelial or skin-cells from the mouth, flat, irregularly oval, large, with or without nuclei. They may easily be obtained in saliva by rubbing the tongue firmly against the roof of the mouth, and may afterwards be identified elsewhere. (4) Salivary and mucus corpuscles, smaller, globular, also in healthy saliva. (5) Blood constituents (*a*), red blood corpuscles more or less degenerated, and (*b*) "leucocytes" or white corpuscles, larger and irregular shape. These may be seen in fresh blood drawn by a needle-prick from the finger; the red are very much more numerous, and look like plates. (6) Bodies resembling white blood corpuscles, but with many nuclei, which are well brought out by logwood. These, more or less degenerated, and granular in decay, form the bulk of the sputum.

## THE MICRO-OBJECTIVE.

[24204.]—MY labours have been in a direction differing from those from whom I have learned much in our pages, for while they have been setting forth the most perfect mode of producing the most perfect o.g.'s, my experiments have been made to discover some more simple plan by which the amateur optician might produce a fair combination.

I will now state briefly the steps which led to my success as it now stands.

The objects to be attained in a good micro o.g. are threefold—viz. (*a*) elimination of the spherical aberration and distortion; (*b*) to counteract or unde the dispersion; (*c*) to obtain greater angular aperture, as compared with a simple lens.

1st. Let this simple lens be a plano-convex, and it will be an improvement upon a bi-convex of same focus; suppose 1in. then.

2nd. Let two plano's, of 2in. focus each, be used in contact, and there will be a further correction of all the errors.

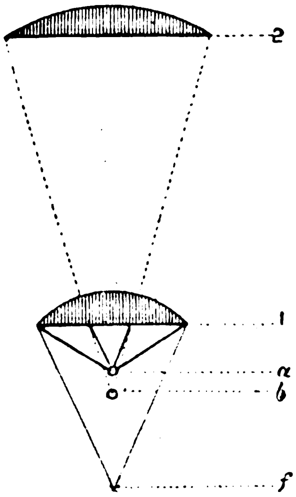
3rd. Separate the lenses increasingly, and the spherical error decreases, as also does the magnifying power; but the spherical error vanishes long before the magnifying power.

4th. Let the focal length of the posterior lens be varied, and it will be found possible to still further improve the general conditions.

These four statements constitute data on which to work.

Now let two plano-convex lenses be placed at a distance apart, equal to half the sum of their focal lenths, and the spherical error will vanish, especially when the shorter focus lens is a thick one. All things considered, too, the best focii for the lenses is the ratio 2 : 1.

A consideration of this fact, by help of a diagram, will be helpful. Herein (2) is a 2in. plano-convex, (1) is a 1in. p.c., placed with planes to object, and 1½in. apart.



The focus of (1) is at (*f*), but the object to be in the focus of the doublet must be at (*a*), when the rays of light from the object, instead of being parallel on emergence from (1), are so arranged that they impinge upon (2), as if they came from a focal point at (*b*), and also as though they came from a concave object of such concavity that every part of it is in the curved focal area of (2). Consequently, the back lens is able to give a view of the object under view as clear and flat as though it had no spherical aberration.

We now have as perfect an o.g. as two positive lenses can make, with perfectly central light (especially of a parallel or slightly convergent beam) the definition of thin objects—fly's wing, moth scales, &c.—is very little troubled with colour, and not at all distorted; neither does the field of view come into focus gradually, nor part at a time; but the whole at once and promptly, even with a large diaphragm aperture to eyepiece.

It is very plain, now, that if the back lens could have a little over correction with regard to colour, that our o.g. would be a perfect thing—at least, so I thought, and so have I also proved in practice with a little modification, which we will consider next week.

Rob. Crus.

## LATHE MATTERS.

[24205.]—I MUST again protest against Mr. Wenham's random statements. He may not intend to mislead our amateur readers; but, if not, he allows his imagination to run away with him, and he has not the courage to set himself right. I again say that of the hundreds of ornamental lathes which are in the possession of the readers of the ENGLISH MECHANIC, and whether made by myself or by Messrs. Holtzapffel or Evans, there will not be found a single mandrel-nose which is hard. Neither Mr. Holtzapffel, nor Mr. Evans, Dr. Edmunds, "J. K. P.," or any other authority will contradict this; and as any reader can test his mandrel-nose by touching it with the point of a penknife without injury, this reply must be final so far as I vindicate the practice of my own workshop.

Whether fine mandrel heads should in future be left hard or soft is a question that should be discussed apart from personalities. Mr. Wenham has taken this idea from Dr. Edmunds's paper, which says:

"The face and nose of the mandrel to be finished as hard as may be without risk of chipping or fracture, so as to secure permanent exactitude in the form of those surfaces upon which the fit of the chuck depends. . . . The nose to be tempered down to blue, and the mandrel-face at its periphery down to straw colour. The face, the cylinder-base, and the thread to be finished off with emery or diamond-dust glazers, so as to leave the surfaces true and accurately gauged. . . . The screw should be well fitted, but so easy as to allow the cylinder and mandrel-face to determine the seat of the chuck."—(*Journal* A.M S., pages 46-47.)

Mr. Wenham has appropriated the above most excellent suggestion without a word as to where he got the idea. In my opinion fine lathe-noses ought to be left of a spring temper, and brought to that state by the hardening process. In this state steel possesses the strongest endurance and the greatest possible strength, but they must be of somewhat larger dimensions than the present ornamental lathe-nose. Unless we adopt Dr. Edmunds's inch nose, such hardened noses would be liable to break off.

I am now making for clients two lathes with the Edmunds' model of mandrel-head, and left as hard as he suggests. Mr. Wenham's assault, therefore, falls idly upon my back; but it is necessary for the protection of provincial makers that such assaults should be fully exposed when insinuated into the columns of the ENGLISH MECHANIC. It is a common trick to take a third-grade article by some provincial maker, get it dirty and damaged, and keep it for exhibition by the side of newly lacquered work for which thrice the price is charged, as a sample of the difference between the work of makers in the country and in London. It is a mean trick, and does not deceive people who can compare prices as well as work. But many amateurs are gentlemen unsuspicious of such tricks, and they are often quite put out of conceit of a country maker's work by misrepresentations made behind his back. The innuendo that any one who is "knowing enough to test a lathe-nose with the corner of a file will not be taken in" is a good exemplification of the illusions to which gentlemen are treated in certain quarters. It never occurs to gentlemen to test in the same way a lathe by Whitworth, or Muir, or the other makers whose work Mr. Wenham eulogises for the moment, just for the purpose of throwing mud at me. Neither of these gentlemen will thank Mr. Wenham for the compliments which he offers them in order to disparage me, and I am certain that they will be ready to admit that, price for price, my goods will bear comparison with theirs.

As to the diamond tools for turning up hard steel lathe mandrels, Mr. Wenham (page 560, line 80), writes, "some of our best lathe makers." I denied this, and asked for names. Mr. Wenham then pretended to be reluctant to advertise his friends, and, on my calling this a paltry excuse, he says, "these lathes are by Continental makers"; and he tries to frighten English makers with the dreadful consequences of publishing Continental names in so widely-circulated a paper as the ENGLISH MECHANIC. Now, if we English makers cannot compete with Continental ones, the sooner we learn to compete, or shut up shop, the better. I therefore again challenge Mr. Wenham to publish the names of makers who really "true up their hardened steel mandrels by a diamond turning tool," and if, as I said, and he now admits, there are no such English makers, I ask for the names and addresses of the Continental makers.

English makers will be delighted to recognise good work, and some of the best French steel work is very fine; but this is also very expensive, and *price for price* we more than hold our own in the quality of our tools. I referred to the old diamond tools used by my great uncle to prove the antiquity of the method which Mr. Wenham stated was so modern. Engineers all over the world now use diamond tools for truing up emery wheels, grindstones, &c.—this is the *modern* practice. My showing this was the cause of Mr. Wenham's desire to traduce my tools; but I will challenge him for a £1,000 to finish and accurately fit a 6in. centre hard cast steel traversing mandril into its bearings by my method, as described in former letters, in one quarter the time, and far more accurately, taking the cylinder-base and shoulder-face into the bargain, than he can with the celebrated sharpened-up diamond tool he possesses, although I have not personally done such a job for 10 years or more.

It will take Mr. Wenham all his time to answer Dr. Edmunds's last letter (24172), and until he either answers the questions, or has the courage to set himself right, I shall not feel it necessary to take any further notice of his letters; but practical workers like myself often learn much from the suggestions made in the ENGLISH MECHANIC by scientific men, and we are always glad to reciprocate by explaining such matters as we can.

At page 191 Mr. Wenham, catching at a straw, says, "'J. K. P.' *truly* remarks that 'a cutter made for a screw of any particular number of threads will not do for any other number.'" Now, our excellent friend "J. K. P." is remarkable not only for his mechanical knowledge and ability with the pen, but also for his transparent honesty and readiness to correct a hasty statement. It will be rather amusing if "J. K. P." finds it necessary to point out that this remark is *not* true, and it will be a practical commentary upon Mr. Wenham's mechanical knowledge. **Edward Hines.**

Griffin Works, Norwich.

[24206]—I INTENDED some time since to have written you upon this matter; but my time has been so fully occupied that no opportunity has arisen until now. I inclose you a tracing of the nose for a lathe mandrel and face plate screwed thereon; good, simple, and thoroughly efficient, free from all unnecessary complication, and not liable to get out of order. In its use all that is required is a fair amount of care, but, beyond all else, "cleanliness."

I always kept a piece of soft wood, which I invariably screwed into all the chucks and face-plates, to remove any matter that may have got into the female threads, and passed the palm of my hand over the back surface of the boss which impinges against the collar of the mandrel, to be sure that no dirt was there, and that the chuck would properly bed against the collar.

The thread being angular will keep the chucks true axially, and the surfaces of the collar and backs of bosses being surfaced true will keep them right on the face.

No cylinder fit is any use, and if put cannot be depended upon for any length of time; it certainly is an addition, but a useless one, and no improvement.

I for many years used sundry lathes, where the chucks would interchange, and the chucks were shifted from lathe to lathe with the work affixed to them.

In one case—my wheel-cutting machine—I turn up wheels in the lathe, unscrew the chuck therefrom, transfer it to the wheel-cutting machine, and cut the teeth in the wheel.

Only bear this in mind—the threads on the noses of the mandrels must be angular threads, and not square ones, all cut accurately to gauges in strong screw-cutting lathes by efficient workmen.

By mistakes and failures an observing man learns more than by any other means.

Many years ago, I was working a well-made lathe by a reputably good maker. The nose of the mandrel had a square thread. From some cause, now forgotten, I had to remove the work from the lathe (chuck and all), to put in another job urgently required. When I rescrewed the chuck on the mandrel nose, to recommence work, I was astounded to find my work out of round—not run true axially. At first I was puzzled. I unscrewed and rescrewed the chuck sundry times, until I found the position it had originally occupied upon the nose, and I then proceeded with work. When finished, I examined the chuck and nose, and found that they were a slack fit; hence the trouble I had.

Had it been an angular thread this would not have happened. I never after that either bought a lathe or made one (and I have made some hundreds) that had the nose screwed with a square thread, but always used an angular one.

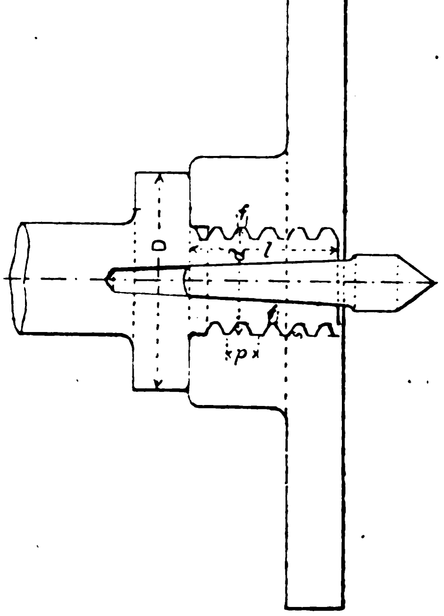
So much has been written by the various amateurs upon the mandrel nose. Simplicity and useful effect are the two great factors. If the thread is too fine, the chucks get jammed on so tight that there is frequently great danger in unscrewing them; besides, the fine thread has no durability, and one made with fine sharp edges is sure to get bruised, and its correctness destroyed. My experience has taught me that comparatively coarse threads are practically more useful than fine ones.

The thread on the nose of a lathe mandrel is put there for a specific purpose, and in choosing a thread, therefore, let us see and consider what will best attain the object. An angular one, whose pitch is not less than one-sixth of the diameter of the nose, or whose pitch is not more than one-fourth the diameter of the nose. That the top and bottom of the thread should be flat and not rounded.

That being so, the thread is more accurately cut, first on the nose, and afterwards on one or as many chucks as may be required.

The flat top and bottom does not stand the chance of being injured as the rounded top and bottom does.

I cannot see any reason why "Whitworth's" thread should be used for a mandrel nose in preference to any other, especially if the other is a better one. When Sir Joseph Whitworth introduced his system of screw threads, some 44 years since, his object, as he explains in his paper read before the Institution of Civil Engineers, was to render screw threads uniform (and, I also presume, universal) for bolts and nuts and other parts of machines. So far, I consider I may fairly say that has been attained, and his name is universally known therewith.



$d$ = diameter of nose of mandrel in inches.

D = diameter of collar of mandrel in inches $= d + \sqrt{d}$.

$p$ = pitch of screw thread $= \frac{d}{4}$.

S = depth of screw thread $= \frac{P}{2}$.

$f$ = flat on top and bottom of thread $= \frac{P}{4}$.

A = angle of thread = 53·0666° = 53° 4′.

A = an isosceles triangle, whose base and height equal.

$l$ = length of screwed nose in inches $= 1{\cdot}333 + d$.

He does not presume that they are applicable to every specific purpose that may arise, or for particular parts of a machine that has to be used in a peculiar manner.

As to the grinding or tapping up the angular threads of a screw or an angular helice upon a cylinder, have these gentlemen who say it can be done considered what the form of the thread will be. Will the sides of the angular thread be (in shop parlance) true?

A screw thread upon a cylinder, whether it be a square thread or an angular one, has its sides twisted, and nothing but a so-called point can truly trace that line. A revolving lap or emery wheel has breadth of surface, and if used for this purpose will distort the thread. **Tubal-Kain.**

## THE PARTIALLY GRAPHIC METHOD OF COMPUTING SOLAR ECLIPSES AND OCCULTATIONS BY THE MOON.

[24207.]—A FEW remarks by way of comment on the slight conferred upon me by the Council of the Royal Astronomical Society in their "rejection" of the paper, which you did me the favour to reprint in your last number, may be of interest to some of your amateur astronomical readers.

And, first, it must not be thought that a humble individual like myself ventured to approach that august body without previous preparation. I had paved the way by a preliminary correspondence with the President of the Society for the present year, Edwin Dunkin, Esq., F.R.S., so long ago as 1876. I think I may say I was almost inveigled into the bold step of addressing the Council by the insidious language then addressed to me. I quote from a letter dated Kenwyn, Kidbrooke Park-road, Blackheath, London, S E.

"1876, Nov. 23.

"My Dear Sir,—I am obliged to you for your letter of the 23rd inst., explaining a graphical method of computing eclipses and occultations. I have carefully examined it, and I think it is a convenient method for the determination of approximate times and angles, and that it might be useful to many for that purpose.

"If you could clearly explain your method in a short paper, it would be worthy of a place in the *Monthly Notices*.—"I am, my dear Sir,
"Yours truly,
"EDWIN DUNKIN."

The expectation thus created of a successful appearance in the *Monthly Notices* was destined to be rudely disappointed in 1885, for when the "short paper" was presented to the Council it was peremptorily "rejected." The secretary was instructed to inform the author that the Council, *after careful consideration*, had refused its admission, on the plea that a *similar* communication had been published in the ENGLISH MECHANIC, and that it was contrary to their *rule* to allow its insertion under these circumstances.

It was added that the paper was "rejected" for that reason *only*. But there must have been some mistake in this account of the matter, for I am told that "the paper was referred to a member of the Council of the highest authority." It appears from the assistant secretary that the paper was taken home from the R.A.S. meeting by Prof. Hind, F.R.S. I conclude, therefore, he was the "authority" referred to. If so, he gives a *different* version of the matter. The *reason* assigned by the "highest authority" is as follows (according to a note just received on the subject):—"Mr. Pearson, I think, fails to see the scope of such a paper as that of Mr. Woolhouse, to which he refers, and which includes the determination of all the lines required for the construction of the maps of solar eclipses, published in the 'National Ephemerides,' as well as the circumstances of lunar eclipses, transits of the superior planets and occultations, and he seems to be under a misconception as to the time any ordinary computor would require for the application of an accurate trigonometrical method to the prediction of an eclipse or occultation for a particular place."

In direct contravention of this statement (which it is evident was the *ostensible*, not the *real*, ground of "rejection"), I may state that I put myself in personal communication with Mr. Hind in 1858, and submitted to him a calculation of the solar eclipse of that year worked out on this very method of Woolhouse, which he checked by causing a copy of the printed form of computation, as done at Greenwich, to be sent to me, thus proving that I am not quite as ignorant on the subject as he would have others to believe. Besides, if the "rule" was absolute, why require "careful consideration"?

But let any one make the attempt of working out a solar eclipse or occultation on the "partially graphic method" (as Mr. Woodside has done), and compare the time occupied with that employed in working the same eclipse or occultation on Woolhouse's or Shadwell's method, and he will decide the question for himself.

Prof. Asaph Hall, of Washington (no mean "authority"), writes:—

"1884, Sept. 18.

"Your method seems to be remarkably neat and short, and is, no doubt, sufficiently accurate for all the purposes of observation. I hope you will publish it."

I trust amateurs will profit by my experience of the doings of a clique. Sir James Simpson had to undergo many rebuffs when he discovered chloroform, and Prof. Adams would have sooner risen to distinction, in connection with the discovery of Neptune, if he had had the support of a certain institution, which might have helped him. Novitiates in science must beware of those who seek more their own aggrandisement than the promotion of learning. **James Pearson, M.A.**

Fleetwood, April, 1885.

## MINERAL OILS AS DOMESTIC ILLUMINANTS.

[24208.]—THE more extended use of liquid hydrocarbons as popular illuminants has been much retarded by a rather general misconception of their nature, and a mistaken classification of various substances as one. Perhaps a few words of explanation in the most popular and simple form about these oils might be of some use, for although all that can be at present written on the subject has from time to time appeared in this journal, and is familiar to most of its readers, yet a little summarising of the matter may be convenient to some.

Popularly, these oils may be conveniently classed as paraffin and petroleum, though the one is a manufactured article and the other in its raw state is a natural production, yet, to all intents and purposes, the same observations refer to the use of both. Now, in a general way, these oils (as far as their use by the public as illuminants is concerned) may be classed as "benzoline," water white, and "standard white." The first is a highly volatile spirit, and should not under any circumstances be used in lamps as a domestic illuminant, as it gives off a very inflammable vapour at a comparatively low temperature, and at present its storage and domestic use are rather dangerous. The second is the whitest and purest oil, and is retailed under various fancy names and prices, at from 50 per cent. to 150 per cent. profit, according to the clientèle of the vendor, and his ingenuity in pushing its sale. The third is the "Standard White" (the title belongs in strictness to the Standard Company, but is here only used as an easily understood definition of a quality of oil made by many refiners). Generally speaking, these are the oils usually sold, and should at present prices be retailed at from 8d. to 1s. per gallon.

The popular idea of these oils "blowing up" must be at once dispelled on considering their nature. The oils themselves never can "blow up": only the vapour that is evolved from them at a high temperature can do this, and then only when mixed with a certain amount of atmospheric air, and as no good lamp of the present day is at all likely to heat the oil to this degree, all uneasiness on this subject should cease; the flashing point being roughly stated as over 150° in a close test, and a permanent firing point of over 250° (see for fuller information "E. M." Vol. XXXIX., page 191). It being thus shown that in the use of these oils there is no danger, the storage of same in private houses should cause no uneasiness.

The lamp, its fittings, and method of using it should next be considered, and among the vast number of these offered to the public, the specification of any particular make might be invidious. Let it suffice to say that in a general way they are all good enough for their purpose, the only object of these lines being to popularise the rationale of lamps in general, and assist consumers to use their own judgment in selecting such lamps as best suit their means and requirements.

The present lamps may be best classed by the form of their wick, the double wick (Duplex), the flat wick, the round wick, so woven (reading lamps, &c.), the flat wick taking a circular form (Silber, &c.), the cord wick used for small lamps and in a large annular cluster (the Argand); there are also excellent lamp modifications of the above, and some with mechanical arrangements that consume no wick. As the comfort and usefulness of all these lamps depends entirely on the care and cleanliness of trimming and using them, a few observations on these points may be of assistance.

In selecting a lamp, see that there is no opening in the fitting except the wick sheath. The fitting should fit the collar by a well-made screw of at least five threads; the container should be of as great a diameter and as shallow as possible, as few wicks will draw well for more than 4in. from their point of combustion. See that the collar is fixed airtight to the container. This prevents the escape and aëration of vapour should it be generated, and compels its consumption by the flame; it also prevents the exudation of oil mentioned hereafter. The pinions for raising should be well made, and have their teeth fine and sharp, and where two are used they should be very evenly adjusted, as, if not, they raise one side of the wick faster than the other, destroying the level of the light. The lamp-stands should be well weighted, and have a good broad base to render them firm and secure.

More consideration than is generally accorded to it should be devoted to the chimney, the special function of which is to cause a steady draught on the flame, and so insure its perfect combustion; without this chimney (which was first accidentally discovered by the younger Argand) no lamp can give a steady or white light. No one can but wonder at the senseless way that perfectly unsuitable forms of glasses are applied to different makes of lamps—not only by the public and retailers, but even by the manufacturers, and many a good lamp has from this cause alone been most unjustly condemned.

In round-wicked lamps the chimneys must be made with a shoulder, with or without a "choke." The latter, perhaps, is the best, for, though it may limit the diameter, it provides a larger flame of white light; in either case the shoulder must be close (from ¼in. to ⅜in.) above the head of the wick tube, and where the chimney "carrier" is fixed (that is not adjustable), care should be taken to provide chimneys so conditioned; otherwise the light will be poor in quality and apt to dance.

For "Duplex" lamps there can be no better chimney than that now sold.

For large or small flat-wicked lamps there is really no very good chimney at present sold, "the square peg being made to fit the round hole"; the best form, however, is one made a good deal in the shape of the "Duplex," that is, more cylindrical and less bulbous than the usual form, and which can be bought in all sizes. The proper form would be an acute oval, choked like those used for round-wicked lamps, only made oval; but fittings for this shape are nowhere made, nor one chimney of this form to be had, although in one Belgian glass-works there are over 300 patterns of lamp glasses. A good general rule is to use as small a glass as will suit the flame; for small wicks and large bulbous chimneys are very often sold, in some cases half-roughed, to act as a compound of chimney and globe. The construction in such lamps is imperfect, and the atmosphere of the room is vitiated by the unconsumed products of the oil.

The glass carrier and dome should be easily removed that the wick may be trimmed, and the sheath and ventage perforations properly cleaned. There are lamps sold where this dome is a fixture, and such can never give satisfaction or comfort in use.

Though the consideration of the wick comes next in order, it is really of the first importance. This should be rather loosely woven, and, without being in any way impacted, should well fill the sheath. Before putting it in the lamp, it should be well baked or dried at the fire; the least moisture prevents the oil readily rising in it; place it in the sheath from the container end, and when through, before being put in the oil, it should be burned at the end to give it a level edge. Scissors should not be used to trim the wick. This is best done with a flat hard brush, such as is used for washing hands, and is sold at 2d. or 3d. Raise the wick above the sheath, and brush off the charred part; then, with the brush, trim it into an elliptical shape, like the section of a watchglass, taking care to keep the corners nice and round, and not to make the ellipse too high, or the wick will not burn at its full width. Keep the lamp well wiped with a soft cloth, and always light it with a wooden match or spill.

When not using a lamp, keep it clean and empty, and when in use, but not lighted, keep the wick well down in the sheath, as the oil mounts it by capillary attraction; and if the wick is above the sheath, the oil flows imperceptibly over the top and extends all over the lamp until the container is quite voided, and much mischief done. This action gives rise to a very ignorant but popular belief that the oil percolates *through* the glass or metal.

An oil "drum," containing from five to ten gallons, should be provided in town, and one of a capacity of forty gallons (equivalent to a cask) for the country, as these oils should never be kept in wood. These drums should have a good sound tap, and the oil may be drawn off in the required quantities without any unpleasant dirt or smell; and any extensive retailer will sell the best oils in these quantities at from 8d. to 1s. per gallon.

Chimneys can be bought quite good enough for general use by the dozen, at, for the large, such as "Duplex," from 3s. to 4s., and the smaller, like "reading lamps," at from 1s. to 1s. 6d., and they are not a bit more likely to break than more expensive articles. When first lighting a lamp keep the wick low, until the chimney is well heated, then raise it to full combustion, and keep it so while lighted; no lamp should ever be turned down, or burned below its proper power.

To extinguish a lamp do not blow it out; lower the wick into the sheath, and raise and lower it a few times quickly. The wick should always reach the bottom of the container, and though it may last months, should be often renewed.

Doubtless all these observations are familiar to most people, some of whom may know very much more of the matter; the pity is that they do not impart this information. In the hopes of their doing so, these lines have been hastily put together. They do not pretend to any fuller knowledge than is supplied by familiarity with the subject, and are only addressed to the general users of these lamps, who, suffering from various inconveniences in their use, do not readily perceive any simple means of remedying them. J. B.

### MINERAL-OIL LAMPS.

[24209.]—IT would be of great advantage to readers if correspondents could confine themselves strictly to the point at issue, which in this case is the respective merits or demerits of glass or metal containers.

Mr. G. B. Postlethwaite, in his championship of "paraffin oil," must be well aware that that is the popular name of all hydrocarbons, as in this form they were first introduced by Mr. Young, and in this sense I am sure Sir Fredk. Abel spoke. Further on, to refute my argument (which has reference only to English domestic lamps), he instances oil stoves, optical lamps, and American street lamps, all burned under other conditions. While combating my assertions, he goes out of his way to prove me right by admitting the advisability of using a cork washer at the collar, which is quite unnecessary in glass containers, as they do not heat.

My observations have been general and impartial. All the replies (except Col. Shakespear's) have been particular and interested, advocating as they do some special lamp or oil, and directly or suggestively hinting at the danger (?) of others.

J. Hughes.

### ENGINE MAKING AT HOME—REPAIRING BOILERS—MODEL TUG BOILER, &c.

[24210.]—IT gives me much pleasure to observe that "J. H." has kindly assisted my desire to ventilate and discuss matters relating to an amateur's engine. The interchange of ideas with a practical and gentlemanly correspondent is not only a pleasure to the parties themselves, but elicits many valuable points of general interest; thus, such a discussion resolves itself into an exchange of ideas, alike benefiting all interested.

Now, as our friend thus very fairly answers my friendly criticisms, he has brought to the front another practical point. In some horizontal engines I designed for a small maker the very point he raises was mentioned—viz., that the hooded end and the core box for it must be arranged to form the stuffing box in the core box. My friend in question had some misgivings as to this, and I suggested two modifications that at once got over the difficulty. One was to cast the cylinders, which were never more than 8in. stroke, with the one end cast on the gland, being, of course, cast with the end and easy to get at or to form the front end as follows: the hooding was cast out, and subsequently bored out in a recessed ring. Into this recess went a disc, having the piston-rod gland on it. The cylinder, when bolted on by its flanges, was maintained central by a rib on the loose cover, and as it was drawn up made a joint with it at the same time that it was bolted to the hooding. These engines had also another modification—the guide was a modification of Fig. 4, the modification being that instead of planing out the path for the guide block, a semi-circular path was used, which was bored out at the same time as the flange on the hooding. The centre line of the cylinder was thus very much lowered and the thrust brought in a more favourable position. The guide shore having been turned also the guide strips were simply flat ones of rectangular section. As far as a practical job goes, I must say that Fig. 5 is very good indeed, the crosshead shoe being made adjustable to take up wear.

I must certainly say that the way "J. H." has treated the matter is exceedingly practical. No doubt the bed he shows is, as he states, so simple that any amateur would experience no difficulty. This is a great point in construction. And I would wish to bear personal testimony that the reasons given by him show that the subject has been most thoroughly thought out by him, and he is clearly entitled to the sincere thanks of the readers of this journal, and I trust they will not be niggardly bestowed.

Has "Os" taken into consideration when he writes on the subject of repairing shot holes in a boiler, at p. 193, that the completion of the work in the shortest possible time is of the greatest importance? He asks me how I should like to get inside. Well, my answer would be that it is not essential to get inside at all, and I mention the *manhole as giving egress*, as showing that, on a pinch, a man could be sent inside to assist. The holding up can be done from the outside; therefore a man inside is not an absolute necessity. Now, to drill and tap holes in the boiler shell is a job that would take some time, and even then there is the making of a joint and screwing up. The piece that "Os" would propose to fix on the boiler would also be outside, so that the pressure within would be resisted by the screwed pins only. In the plan I named, the strain is borne by the piece of plate itself, the outside piece being used to draw the joint up with; so that in my example the repair is as strong as any manhole joint can be, being an exact equivalent. If studs or bolts screwing into the thickness of the boiler shell be so simple and effective, then why are manholes not made so, instead of fitting against the inside exactly as I say?

I can quite understand the idea that is floating in the mind of "Os." But I can tell him of a much more nasty job than going inside a boiler to hold up whilst the joint is being drawn up, and I have had personal experience of it. It is going into the return of a large boiler to plug up a burst tube. Now this is a job I don't care for. It may be instructive to our friend, so I will briefly describe it: A tube having burst, the water is blown out. The steam jet is started, and as much air sent through the boiler to be repaired as possible. The fire bars are pulled out, and in you go into an atmosphere heated to something terrible. With the aid of a short-handled sledge or a heavy fitter's hammer you drive in the wood plug, which you have prepared, into the end of the burst tube; a blow or two to drive it in steam tight, and you are frequently even then dragged out by your heels by your firemen next door to fainting. The patent tube stoppers were not in use in my time, so that it meant going in in person. Now has "Os" ever done this? I have, and would do it again if occasion needed. Here we have, in my opinion, a job that is done under conditions still more trying than sending an Arab fireman into a boiler, the Arab being able to bear with impunity a far greater heat than the writer. And we have also another factor in the case. It is that the plates and boiler originally mentioned could readily have been cooled by copious volumes of water whilst the covering plate that friend "Os" mentions was *drilled with clearing holes*. In my case the boilers were empty only, and were not cooled by water sent in for that purpose. In repairing shot holes, when I have been present, water was plentifully sent in by either a hand pump or in buckets, and the temperature quickly reduced so that it was bearable, to blacks at any rate. I do not wish, nay, I will not say, anything that may even savour of an acidulous reply to "Os"; but perhaps he would not mind my asking him: Has he ever, in person, dealt with a burst tube as I describe? And has he also had practical experience in stopping shot holes in a boiler? If he has not, I have, and can speak from what I have gone through in person, and the ordeal in either instance is not *nice*. I have seen some practical repairing of war ships that would surprise many of our friends, "The gentlemen of England, who stay at home at ease."

In referring back for another matter, I chanced to see the reply on p. 153 (query 56240). Surely our friend J. Anstie must have made a mistake on the question of tubes. He advises 40 tubes, 7-16in. diam. outside, and about 9¼in. long. Surely he must know that such small-bore tubes are practically useless, as, allowing for metal, the clear bore would only be at most about ¼in. diam. Again he discards a steam dome, yet has for water and steam but 1¾in. over the firebox crown. The engines also, in my opinion, are far too small to get the maximum speed out of the hull. I certainly think our friend must have made a mistake in respect of the space for steam and water, whilst the steampipe, ¼in. bore, is none too large. It is very easy in writing off a quantity of figure dimensions to make a mistake, and I fancy this must be so. Again, the safety-valve for a boiler with a large furnace in it, as he mentions, seems very small, especially if life is worth anything. Now a pump on the engines looks well, but if they were driven at the speed I should want to run them at, I don't think the pump would do much feeding. Certainly it must be a better one than I have been able to get as yet, especially when it has a ¾in. plunge and only ¾in. stroke, and has to feed against 60lb. steam pressure. No doubt our friend will be able to tell us something further, and, I should imagine, would see his figures have been transposed. If not, I am certainly at a loss to understand his practice. Our friend must, and will, I am sure, take my remarks as friendly criticism, and, no doubt, will at his convenience afford some explanations of what seems to me unusual. **Invicta.**

### THE MUSICAL SCALE.

[24211.]—IN letter 24096, No. 1048, I should have said tune monochord to *tenor viola C string*, as tenor C really means an octave higher than I wish it to be understood. I have to ask the Editor's forgiveness for the error.

New Cross, S.E. **W. H. Elphick.**

### NEW MIDLAND ENGINES.

[24212.]—THERE has been a deal of mischief made about the new Midland engines, but the letter of "Locomotive Man," p. 172, clears all up. It is as plain as daylight now that the engines are failures from *one* cause, and that is a bad one—shortness of heating surface. It is all very well, Sir, for all the blame to be pushed on to the drivers, just so that the truth shall not come out. Whoever did the calculating of dimensions made a fearful mistake in putting on these little boilers, but let *him* have the blame, not the drivers. I hear they are going to put a lot more tubes in the boilers now, after all this correspondence; let us hope that plan will do good, and get more steam.

It may be a matter of interest to your numerous readers to know that some more tubes have been put into the boilers of some of the new Midland engines, and it is an improvement; last week No. 1675 ran the Scotch Express to time upon two occasions, taking the twelve coaches without any pilot. In looking over the ENGLISH MECHANIC for a few years back, I notice that at that date our correspondents, Mr. Stretton or "Meteor," always came forward to defend the 800 Midland engines if a word was said against them; but these two gentlemen do not seem to enter into this important matter of the 1675 class. Have these "big engines" no one who will come forth and do battle for them in the "E. M."? I rather expected that with big cylinders and Joy's gear we should have had good results. **Midland.**

### RAILWAY-AXLE LUBRICANTS.

[24213.]—THERE is a subject that might, with profit, be discussed in your columns; it is the question of railway-axle lubrication, and the points I should like to see settled are:—

1st. Which is the better lubricant, grease or oil?

2nd. What is the best form of axle box?

3rd. The successes as regards capillary attraction, and the arrangements for dropping the oil upon the axle. **Lubricant.**

### CONTINUOUS BRAKES.

[24214.]—THE return relating to continuous brakes in use to 31st December, 1884, has recently been published; but, unfortunately, like its predecessors, it furnishes evidence that at present there is no prospect of the adoption of one general system, and that several companies are actually continuing the absurd practice of fitting rolling-stock with inefficient brakes, showing practically that they care neither for the safety of their trains nor for the waste of their shareholders' capital.

| | Engines fitted with brakes. | Engines fitted with apparatus for working brakes. | Carriages, &c., fitted with brakes. | Carriages, &c., fitted with pipes, chains, &c. | Miles run. |
|---|---|---|---|---|---|
| Total amount of stock returned as fitted with brakes which appear to comply with the conditions of Board of Trade | 3,066 | 90 | 19,047 | 4,037 | 31,953,436 |
| Total amount fitted with brakes which do not comply with the conditions | 1,111 | 482 | 13,005 | 3,049 | 21,854,973 |
| Total fitted | 4,749 | | 39,138 | | |
| Not fitted with any continuous brake | 1,705 | | 11,374 | | 15,881,925 |
| Total passenger rolling-stock therefore | 6,454 | | 50,512 | | |

It should be mentioned that the Board of Trade has considerably improved the form of the "return" by placing engines and vehicles which are fitted with brakes complete in different columns from those which have "apparatus for working" or through pipes or chains only; the percentage of vehicles and mileage on each railway is also valuable information.

The above tabulated statement shows the amount of rolling-stock fitted and unfitted on 31st December, 1884.

The above figures show very plainly that the majority of railway companies are not making sufficient progress, for out of a total of 6,454 engines only 3,066 have brakes which even "appear" to be efficient, and of 50,512 vehicles only 19,047 profess to have those brakes, and it must also be remembered that (to use the words of the return) "some of the brakes so returned but very imperfectly fulfil that designation." For instance, the North London Company returns 83 engines and 560 vehicles fitted with Clark and Webb's chain brake as fulfilling the "conditions" of the Board of Trade. It is not necessary for me to say that it does nothing of the kind. Then, again, the Midland and Great Western Companies take credit for a large number of engines fitted with non-automatic steam brakes, and vehicles provided with that most dangerous of all appliances—the Clayton two-minute leak-off system.

No person can honestly say that the "leak-off" brake is safe, nor that it fulfils those well-known and excellent "conditions" contained in the circular of 30th August, 1877.

Having given the total amount of stock fitted, reference should now be made to the actual "progress."

The following table shows the total number of engines and vehicles which were fitted with each system during the half-year ending 31st December, 1884:—

| Name of Brake. | Engines. | Vehicles. |
|---|---|---|
| *Westinghouse Automatic.. | 97 | 601 |
| †Sander's and Bolitho Automatic Vacuum........... | 64 | 534 |
| Smith's Automatic Vacuum. | 87 | 339 |
| Clark and Webb's Chain.... | — | 20 |
| Smith's Vacuum........... | 46 | 259 |
| Newall's.................. | — | 10 |
| Vacuum (L. and N.-W.).... | 7 | 671 |
| Heberlein................. | — | 3 |
| Westinghouse Pressure..... | 6 | 54 |
| All other Systems.......... | — | — |
| Total................ | 307 | 2,491 |

* In addition to the above, 25 goods engines on the North-Eastern Railway have been fitted with the Westinghouse brake.

†The 64 engines fitted with Sander's brake have non-automatic steam brakes.

From these figures it will be seen that sufficient progress was not made during the last half-year, and it must also be remembered that a large amount of stock returned as fitted in the six months is nothing more than a change of system. The London and North-Western Company appears to have fitted a large number of vehicles with the "Vacuum" brake. This is not progress, as another brake—the Clark and Webb chain—is being taken off, and it is by no means certain that the new "simple vacuum" is a better or safer appliance than the discarded "chain."

The following table is obtained from a comparison of the last two returns, and shows that during the half-year the undermentioned brakes were removed:—

| Name of Brake. | Engines. | Vehicles. |
|---|---|---|
| L. and N.-W. Ry., Chain.. | — | 881 |
| West Coast Joint Stock Chain................. | — | 77 |
| Great Eastern Ry., Smith's Vacuum............... | 5 | 70 |
| Great Eastern Ry., Fay's.. | — | 3 |
| Lancashire and Yorkshire, Fay's................. | — | 28 |
| Great Western, Smith's Vacuum............... | 4 | 55 |
| Caledonian Ry., Steel McInnes............... | 1 | — |
| Total.............. | 10 | 1,114 |

The fact that in six months companies should take off such a large number of inefficient brakes shows the absurdity of money having ever been thrown away upon fitting them.

The most unsatisfactory part of the Return is again that portion relating to "failures," the information in many cases being either incorrect or absolutely false.

The Manchester, Sheffield, and Lincolnshire Company reports an actual "failure" under the head simply of delay.

The Midland Company reports one case only of the failure of the "two-minute leak-off vacuum," yet it is a well-known fact that numbers of failures have taken place, causing trains to run past stations and signals. This is not hearsay evidence, as I have seen some cases and been in the trains; therefore to these I can speak with certainty.

At the Congress of the Amalgamated Society of Railway Servants, held at Bath last year, it was distinctly stated that "failures" were not reported by the companies, and nothing can confirm the truth of that statement more than the recently published return. **Clement E. Stretton,**
Hon. Member A. S. Ry. Servants.
Leicester, 2nd May.

### HOW TO MAKE UP A SET OF RESISTANCE COILS.

[24215.]—HAVING received many letters asking for advice on the above subject, from those who have purchased the standard ohms which I advertised in this paper, I proceed to give the information publicly, trusting that it may be of general interest.

Although coils may be made up without the use of a Wheatstone's bridge, yet the employment of this latter will greatly facilitate operations, and will conduce to greater exactitude. A simple bridge, which is perfectly suitable for this purpose, may be made from a piece of dry, well-seasoned pine, about 16in. long, by 4in. wide, and ½in. thick. After being planed up true, this may be stained and varnished. A strip of copper, about 12in. long by $\frac{1}{16}$in. thick and 1in. wide, is screwed down against one edge of the upper face of the board, leaving 2in. at each end uncovered.

Two strips of the same copper, 1in. wide, but only 4in. long, are now to be fastened down to the board, across its width, one at each end. This leaves a gap between the long strip, and the two short ones, of birch, at each end of this board. Ten small telephone binding screws are now provided, and inserted: First (*a*) one in the centre of the 12in. strip of copper. (To this one pole of the battery is afterwards connected). (*b*, *b*), one at each extremity of the 12in. strip.

Secondly (*c*, *c*, *c*, *c*), one at each top corner of the 4in. strips, facing the 12in. strip; and lastly (*d*, *d*) one in the centre of the lower extremity of the 4in. strips. Between these latter two about 14in.

of No. 30 soft iron wire can be stretched when required by passing through one binding-screw hole, clamping, passing through the hole in the opposite binding-screw, pulling pretty tight, and then tightening up this latter screw.

Before putting the iron wire in its place, a simple form of contact key is slid on the wire, by which contact with the other pole of the battery is made when required at any given point along this stretched wire. This consists in a little inclined plane of wood, on the highest portion of which a binding-screw (for attachment to battery) is fixed. This screws down upon a flat, thin spring, which, on being depressed, makes contact with the wire.

Now for the way of using this bridge. Connect one pole of the battery with the sliding contact (which must stand at exactly half-way between the two arms of the bridge) and the other pole with the binding-screw in the centre of the 12in. strip. (N.B.—The battery had better be a Daniell, charged with sulphate of zinc, in order to be very constant.) A fairly sensitive galvanometer should now be connected to the two outer binding-screws at the farther end of the 4in. strips. A standard ohm is now placed in the gap between the long strip and one of the short strips, and connected to both by means of the binding-screws. A length of the wire which it is desired to make up into a coil is now placed in the remaining gap, and connected up in the same manner. The key of the shifting contact is now momentarily depressed, so as to allow a current from the battery to pass. If the trial wire is of the correct length between the gap, *no deflection* of the galvanometer takes place, as the standard ohm and the said wire balance each other; but if a deflection is shown to either side, the sliding contact is shifted to the one side or other, and depressed until balance is obtained, then by noticing on which side the extra resistance has been inserted (which side has the longest piece of iron wire to the right, or left, of the sliding contact), it is easily seen whether too much, or too little, wire has been placed between the gap. This length, making allowance also for the length required for soldering, or otherwise fastening to the copper poles, or binding screws of the desired coil, may now be cut off, the wire folded once on itself, to prevent self-induction, and wound round a reel, the two free ends being soldered (with rosin as a flux, *not* chloride of zinc) to the desired terminals. Before definitely soldering down, the reel and its connections should be again placed in the bridge to insure perfect accuracy. It is needless to say that the wire should be German silver, insulated with silk, and well paraffined.

From the 1-ohm just made, a 2-ohm and a 5 can easily be measured, and from these any number up to thousands can be constructed. A convenient set consists of an arrangement of 1, 2, 2, 5, 5, 10, 20, 30, &c., up to 100, double the hundreds, and also the thousands. **S. Bottone.**

## THE NEW THEORY.

[24216.]—IF J. L. Gordon expects any sane English Mechanic to believe his theory, I trust he is mistaken. As jokes are out of place in this paper, I suppose we must try to look sober while we argue about the "expansion of energy" and the "flashing train of atoms."

I fear that the law of the expansion of energy has not been properly investigated, for I have never succeeded in finding the coefficient of expansion in any table.

I am quite at a loss to see how dynamos can generate a current of the "fleeting H." Perhaps "J. L. G." can tell me at what part of a dynamo circuit is the H evolved, or what part of a thermopile generates the "fleeting H"? He, of course, with that delicate instinct which leads him to such correct conclusions in the field of mechanics, will have a better chance of solving these problems than we who depend solely on reason.

It is alleged that the intense heat of the electric arc is caused by the hydrogen burning. Suppose that the wires of the dynamo are charged with a limited number of hydrogen molecules, the arc would rapidly burn the H, and the dynamo would cease to give a current. If I may be allowed to tender a little advice to this dashing theorist, I would say—First. Study the first principles of chemistry, and learn that an *atom* cannot exist free in nature, and, second, before you write a book on your new theory, learn that *whenever* a current passes through a wire, heat is evolved.

**A. H. B.**

## A DISAPPOINTMENT.

[24217.]—SEEING "Montmartre's" kind offer anent opera-glasses of high power—a great dedesideratum—I wrote, inclosing £2 16s. 6d., for a glass "of superior manufacture," mentioned in a former reply to the secretary of the A. and N. Cooperative Society. In answer, I received back the money, with the intimation that the rules of the society do not admit of goods being supplied to non-members. As I mentioned the advertisement in the ENGLISH MECHANIC, there must have been some misunderstanding. I am much disappointed, as I expected to be in the enjoyment of a treat by this time. **G. Dickson.**

## LATHE MATTERS.

[24218.]—WHAT "J. K. P." has told us of his magic "touch" makes me long to know more. Will he kindly describe the process, and say a word as to the degree of accuracy before and after the operation?

The question in our minds must be, If "J. K. P." can make a mandrel nose with a screw so perfect that it will enable chucks to be exchangeable without the need of a cylindrical fitting, why cannot Mr. Evans or other first-rate workmen do the same? Then the suspicion that he may be contented with a less degree of accuracy forces itself upon the mind; but does not satisfy those who have been accustomed to think of him as representing the highest attainable accuracy of workmanship.

Does "J. K. P." use any methods that are unknown to other workmen? Can we adopt some test by which the accuracy of the results of the two methods under discussion can be compared?

I should much like to see the drawing of the front slide lathe in the *Machinist* mentioned by Mr. Myall. Can the number for March 7th be obtained in this country, or will he lend it to

**F. A. M.**

32, St. James's-road, Tunbridge Wells.

# REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[54825.]—**Salt, &c.**—I am not at all surprised that "F. W. H." never heard of "corn and baked cakes of bread having been found fossilised in the geological strata." I never heard of it either, nor I suppose anybody else, and why "F. W. H." should have introduced the geological strata is more than I can tell. The remains of man that I referred to were what has been found at the Swiss Lake Dwellings, and instanced them as showing that those men were not primitive, although they were so early as to be living up to the ice border at the time the Glacial period was moving off from that and the northern part of Europe, and among the things found at Rosenhausen were traces of bronze, pieces of pottery, portions of woven cloth, and some crucibles, one of them having a small bead of copper in it. At Wangen were found quantities of corn, baked cakes of bread, flax, and perforated stone axes. I suppose this will be enough. In the following answer (54825) by "Nun. Dor.," he seems to object to a special creation for the different food plants, and says: "It is much easier to believe that they have been developed by cultivation." But supposing they were so developed, it does not take away the need of a special creation, because if the different qualities which go to make up the various plants had not been in the originals, they could never have been developed, according to the law that you cannot get out of anything what's not in it, so that we are just where we were. —DENS.

[55522.]—**Hexagonal Parts of Globe-Valve.**—If you have the means of attaching a horizontal division-plate on your slide-rest, you could bolt the globe-valve on it and shape the hexagon with a milling tool held in a suitable chuck. "O. J. L.'s" much-abused "Unlimited Liability Lathe" (Vol. XXXVIII. p. 507) would probably be useful, in default of special tools.—GLATTON.

[55535.]—**Boiler Chimneys.**—Rankine gives $\frac{1}{10}$ area of grate as the area of chimney; Bourne gives as Boulton and Watt's rule: Area of chimney in square inches—

$$= \frac{\text{lb. coal burnt per hour} \times 12}{\sqrt{\text{height in feet}}}.$$

There are many others. The chimney should be equal to the sum of the areas of the chimneys which would be required if each boiler had its own. Molesworth gives a rule similar to Bourne's, but substitutes 15 for 12.—GLATTON.

[55565.]—**Cone Pedals.**—Yes, there is a bending stress due to the pressure of the foot. I have not an opportunity of measuring one; but I think the pin on which a bicycle pedal turns is about ½in. diameter.—GLATTON.

[55634.]—**Engine Boiler.**—This is too big a job to undertake without special tools. The valve you sketch is faulty in several respects: it is unbalanced, and would not work freely: the rectangular section is bad for strength. You do not say what pressure you wish to work at. ¼in. plate would do (if carefully riveted with double riveting for longitudinal seams) to work at 50lb. per square inch, the best plate being used. Could you bend and punch or drill plate of this or a greater thickness?—GLATTON.

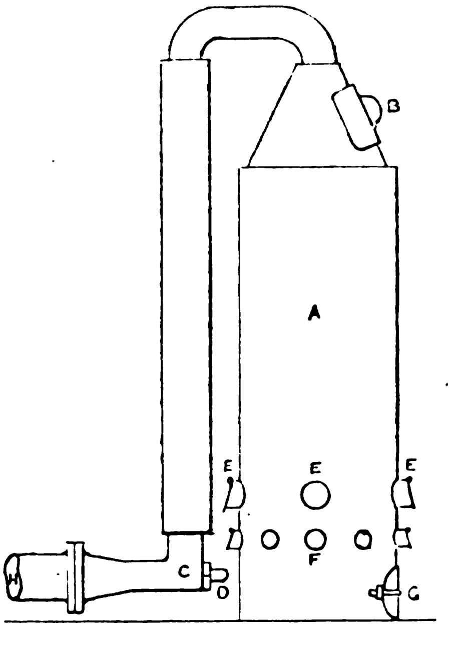
[55700.]—**Strength of Shafting.**—I was glad to see "G. O. T.'s" letter: his is a far simpler demonstration than mine. He will see that the mistakes he refers to were slips of the pen, which I corrected as soon as they appeared.—GLATTON.

[55700.]—**Strength of Shafting.**—On reading "Glatton's" reply to this query in the "E M." for April 24th, I noticed several clerical errors in the concluding sentences; but the preceding portions of the answer made the meaning of the writer so clear, that I did not think the mistake required correction. Another correspondent signing himself "G. O. T.," who has evidently read only that part of the reply in which the slip of the pen occurred, seems to suppose that the whole answer must necessarily be wrong. The new "demonstration" is, however, far less satisfactory than the one already given by "Glatton;" and I think, in common fairness, "G. O. T.," when he wishes to pose as a critic, should in future refrain from slashing at isolated sentences until he has taken the trouble to read the context.—BACCHUS.

[55700.]—**Strength of Shafting.**—To "GLATTON."—In your reply to me in "Ours" of the 24th ult., you say if I work out the power again, I shall find I have made a mistake; the 6in. shaft comes out exactly nine times as strong as the 2in. one; but do you not, in your correction made in last issue, prove that I was right? I stated a 2in. shaft at 20 revs. by your rule gave 4·47 h.p., and a 6in. shaft at 20 revs. gave 121 h.p., which is exactly 27 times the power of the former, and does not this show that the passage I quoted from the book mentioned by me before is altogether wrong and misleading. I beg to tender my best thanks for the great trouble you have taken to explain the matter to—ONE IGNORANT.

[55717.]—**Agricultural.**—I do not know the rule; but if H. Hannen likes to give the usual proportions of such heaps, I might put him in the way of making a rule for himself.—GLATTON.

[55875.]—**Cupola Blast.**—To "INVICTA."—Some matters of further experiment have caused a delay in my reply to this querist. But I now inclose a sketch (not to scale) of the cupola in question.



A is the cupola of usual construction, with the exception that the top is closed, and the coke and charges of iron are fed in through the door B. The hot gases are taken off by a bent pipe and then downwards. The vertical down pipe is surrounded by a light outer casing, leaving an annular air space between the down pipe and the casing; at the bottom at C is a steam jet fitted with a faced cone, so that the jet itself is an annular one. The steam pipe enters at D. At E is one of a series of large air inlet ports. And at F a similar set of double the number but of much less size. All the inlet ports have flap lids, which are made to hang more or less open by a chain and hook. O is the usual door through which after the blow the contents are raked out. The sizes of both E and F are entirely dependent on the size of the cupola itself. Much good has in practice resulted from the addition of the annular casing round the down pipe. H is carried to any convenient chimney or flue. Some little management is wanted at first or a mass of partly melted iron would form at one of the blast holes E or F. But in practice, as soon as this is observed the lid is closed, and in a few minutes the part fired iron disappears. I shall be, of course, happy to afford any other information I may have on this subject, as the rough sketch only explains the rudimentary idea.—INVICTA.

[55897.]—**Internal Resistance of Battery.**—The E.M.F. of a Bunsen cell will be considerably lessened by using sal-ammoniac in the zinc compartment—that is instead of sulphuric acid diluted on account of the action of the sal-ammoniac on the zinc being so much less intense than that of the sulphuric acid, I should think that the internal resistance would not be affected or if anything reduced by using sal-ammoniac. Surely "Bunsen" might find out by experiment what quantity of crystals of bichromate of potash to add to the nitric acid; about ¼oz. to a pint will be sufficient. I should think that the ten cells all connected in series would only light two 5 c.p. lamps, if that. I should advise "Bunsen" to join the other set of five cells in series. I think he will get the required result. The multiple system of connecting cells is only intended to be used when the external resistance is less than the internal resistance. The connecting of a battery in series, called an arrangement for intensity, is used to overcome a great external resistance, the best results, however, being obtained when the external and internal resistances about balance each other.—J. KEAN, Northampton.

[55962.]—**Gas Reaction Wheel (U.Q.)**—How do you make the joint gas-tight? I should think a mercury trough with an inverted bell dipping in it, both made of iron, would make as free a joint as anything. I do not know how those I have seen in the shop windows were made, but I think the length of arm is about right.—GLATTON.

[56025.] — **Trueing Grindstone. — Patent Law.**—As it is now quite settled that we may make a patented article for experiment (p. 195), I may just as well say that I have not ignored the prohibition in the grant, and, as mentioned on p. 174, quite appreciate the difference between the granting and the prohibition clause, even to splitting the hair between "make, use, exercise, *and* vend," and "make, use, exercise, *or* vend." I wanted to show that one must not "make use of" a patented invention, and had no occasion to explain all the prohibitions against selling, &c.—NUN. DOR.

[56041.]—**Gun-Metal.**—I have read "Nun. Dor.'s" letter, p. 196. I see that he is driven to support his argument by suggesting that bronze, when melted in a cupola in which iron has been melted, will contain a trace of iron, which improves it. Still, this was an accidental incorporation of iron with the bronze. In Dr. Ure bronze for cannon is stated to be copper and tin (see p. 460, edition of 1861). The title "Gun-Metal" does not occur in my edition of Ure; but under title "Artillery," p. 202, occurs a sub-heading, "Cannon of Bronze," and at p. 203 it states these guns present every variation of copper and tin from 7Cu + Sn up to 83Cu + 4Sn. Again, at same page (203), "Brass ordnance are made of what is called gun-metal, 10 parts of copper and 1 of tin." But "Nun. Dor." has gone far away from the original question—viz., whether gun-metal, as ordinarily known and used in a workshop, contains iron? In other words, if I order a chuck, or other casting, to be made of gun-metal, should I get a casting which (except by the accident of the alloy having been melted in a cupola in which iron has been melted) contains iron as one of the alloys? Is not this the true question? —Z. Y. X.

[56112.]—**Testing for Arsenic in Wallpaper.**—Mr. J. Kean, in his reply to my critique, states that the query was not how to distinguish arsenic from antimony, and that antimony does not find a place as a colouring matter in wallpaper. Granted that it is so. But he must not forget that an inexperienced person would not hesitate to apply the test in any other case in which he might suspect the presence of arsenic, for he would naturally think that if the test was good enough for the presence of arsenic in wallpaper, it should be equally good in any other case, and which case might contain antimony instead of arsenic, and obtaining the result as described by Mr. Kean, would at once conclude that arsenic was present. Mr. Kean must know that some, at least, of the subscribers to our well-known paper are not so well coached in chemistry as himself, and I contend that to make his reply complete he should have pointed out the error which could be made by the use of Marsh's test by an inexperienced person; and it was to avoid this that I pointed out what I thought Mr. Kean overlooked, but not with the object of casting any reflection upon him, or of raising a discussion. —R. FORREST, St. Helen's.

[56189.]—**Books on Brickmaking.**—Thomas Plunkett will find practical information on brickmaking in "Bricks and Tiles," by Dobson, published by Crosby Lockwood and Co., and in "A Practical Treatise on the Manufacture of Bricks, Tiles, Terracotta, &c.," by C. Davis, published by H. Carey Baird and Co., Philadelphia. — F. CHADWICK.

[56209.]—**Sunshine Recorder.**—There are some notes on the various sunshine recorders in Vol. XXX. p. 476, and the correspondent can see one at almost any philosophical instrument makers.—CYRAX.

[56223.] — **Grinding and Polishing Plate Glass.**—This querist wants something like a lapidary's mill; but, of course, he will find full details in the papers on grinding and polishing glass specula.—J. T. M.

[56225.]—**Spray.**—Surely, this is a very comical query. The apparatus "ought to have acted," says the querist, but it didn't; and he expects that some one will be able to tell him why, when, as the matter stands, it is a puzzle to conceive what the apparatus can possibly be like.—E. G. M.

[56226.] — **Frame Gilding.** — If this querist would look through back volumes, he would find much information on the subject; but as he asks whether there is any book, I may tell him there is the "Practical Carver and Gilder's Guide."—FRAME-MAKER.

[56229.]—**Cholera Bacillus.**—The "scientific aspect" regarding the alleged "cholera" bacillus is just simply that nothing definite is known. The comma bacilli are at present discharged with a verdict of "not guilty," or "not proven."—NUN. DOR.

[56233.]—**Intensity Coil.**—If this querist will only take the trouble to refer to back numbers, he will find that he must try for himself. No one can answer such questions, except by stating what has been done with other coils, without trying.—NUN. DOR.

[56234.]—**Wimshurst Machine.**—This machine does not depend for its efficiency on the thickness of the glass discs, but it looks better to have them ground on the edge. The "current generated" is not a current at all; but the sparks follow one another with sufficient frequency and intensity to vaporise metals. Suppose "Spectrum" reads up the subject of static electricity in one of the text-books.—NEMO.

[56242.]—**Relation of E.M.F. of Dynamos to their Size and Speed.**—In order to express the E.M.F. of a dynamo quantitatively—

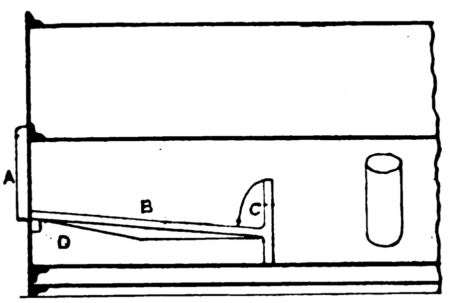
Let M = the intensity of the magnetic field, the unit of which equals $10^8$ centimetre gramme second units.
R = No of revolutions of armature per second.
N = No. of turns of conductor on armature.
A = area in square centimètres inclosed by one turn.

Then, electromotive force in volts = 4 R M N A. In practice the intensity of the magnetic field is only to be obtained by experiment, as no mathematical formula can accurately express it, depending as it does on the quality and quantity of the iron, the shape of the magnets and pole pieces, the shape and position of the coils, the magnetising current, also the quantity of iron in the armature. The graphic method of characteristic curves forms a valuable practical aid to the construction and perfection of these machines. I have this week measured some Siemens dynamos, of which the following particulars will show the influence of increasing the quantity of iron. In these machines the field-magnets are formed of rectangular bars of best wrought iron, six on each side, united by a yoke of cast iron at each end. The middles are bent out in a circle, forming two consequent poles around the armature. The first machine giving a current of 60 ampères and an E.M.F. of 60 volts at 1,010 revolutions per minute. Height, 30in. F.M.'s contain 568 cubic inches of iron = 149lb. Compound wound. The next machine, also giving current of 60 ampères and 60 volts, but at a speed of only 730 revolutions per minute. Height, 30in. F.M.'s contain 768 cubic inches of iron = 215lb. Compound wound. The third machine, giving a current of 60 ampères and 100 volts, at a speed of 900 revolutions. Height, 38in. F.M.'s contain 1,200 cubic inches of iron = 336lb. Shunt wound. The armatures of these machines are similar, being 9in. in diameter by 12in. long; total weight, 131lb. They are wound with 20 coils, each coil of four layers of five wires each, forming 200 complete turns and a 40 part collector.—EUGENE BROWN, Newcastle.

[56245.]—**Britannia Company's Foot-Power Circular Saw.**—Permit me to point out that, as the statement referred to is made by the company, they will no doubt have pleasure in showing the querist that it is true. If anyone were to come forward and say he has "seen the facts stated," "Z. Y. X." would still deem them extraordinary, and probably enter into argument about the perspective of the machine.—ESSAR.

[56246.]—**Legal.**—This query is of no interest to anyone but the persons concerned, and "W. H. B." would do well to consult a solicitor, giving him all the facts, and the opportunity to peruse the leases and any agreements.—LIMB O' TH' LAW.

[56271.]—**Portable Engine.** — To "INVICTA." —Pray no thanks. It is always a pleasure to help an amateur. And if you will recollect, there is a proverb—"That it is as much a pleasure to give as to receive." Therefore, all I can do to assist you at any time, you are most freely welcome to. To answer your question properly, I must again ask the forbearance of our mutual friend, the Editor, for space for another sketch. Now, the firebox is simply a portion of the furnace-tube, in which no cross water tubes are fitted. A is the firedoor and fittings, bolted to the front plate of the boiler. B are firebars cast in one, with a bridge piece as shown; the bottom part filling the curve of the furnace-tube. A piece of fireclay C rests on the bar ends, and prevents the intense heat distorting the vertical bridge. At the front end the bars are carried by a bar across the furnace D, and to this a bolt or cast projection secures the bars B, so that in stoking you do not push the entire erection down the furnace-tube. If you don't understand any other detail, I am happy to explain. In reply to your latter query, I have assumed a coal fire would be used, and you may consider that the boiler in question and the engine of the size you originally name would drive a family sewing-machine nicely. Of course, supposing a suitable pressure of steam be used, say, 25lb. to 30lb., or so, the length of firebars should be equal to the diameter of the furnace-tube—or 7in. long. In starting a fire in such a boiler, a fire-lighter such as we use for household purposes, is a very handy thing, and is a long way superior to paper and sticks. Cover the bars with coal the size of hazel nuts, and put the fire-lighter next the fire-door, packing it round with more coal; apply a match, and you will soon find a good fire, and steam rising quickly.—INVICTA.



[56291.] — **Wheatstone's Bridge.**—Twelve No. 2 Leclanché cells would be most suitable for testing the resistances named with 1,000 ohms out in each of the back arms of bridge known as A and C; multiply the resistance which is out in the three front arms, B by C, and divide by A, which is the total measurement. In testing short lengths of wire, great care must be exercised not to apply the battery current too long; otherwise the bridge coils will become heated, and their resistance will be increased.—J. C. BARTER.

[56303.]—**Blowpipe Lamp.**—Why not try one of the small benzoline spirit lamps, sold for fourpence half-penny or sixpence. They are fitted in the manner described by Col. Ross. By pressing the top of the wick-holder into an oval form, and using ball-cotton wick, you will obtain a clear blue flame, with but little smell, and no trouble of trimming. I have made one from the lower half of a condensed milk-can, with the wick-holder of this shape and size (section) ⬭ and nearer one side for convenience in using. With this lamp I get a flame, the inner blue part of which is 2in. long, and from the burner to the extreme end of the outer, almost invisible flame, 8in. or 9in. I find this little lamp extremely handy and clean. It is doubtful, perhaps, whether it gives quite the amount of heat to be got from a lamp burning olive oil, and upon this point I should like to have the opinion of someone who has tried it. If any-one will tell me his experience I shall be much obliged. While writing this, I must thank Col. Ross for his kind and detailed reply to my last letter.—W. BEVINS.

[56346.]—**Sellers' Screw Thread.**—I note that, by some mistake, the formula I gave for this has been set up incorrectly. I have referred to my copy, taken by the ink process, of that I sent you, which please refer to. The formula as it stands does not convey the proper meaning. It should stand thus—

$$p = \frac{\sqrt{16 \times D + 10} - 2\cdot909}{16\cdot64} \qquad (1)$$

The vinculum is on p. 198 prolonged beyond the 10, whereas it should have ended at the 10. Please correct, or your readers will be mystified and puzzled. In the (7) I find the figure 8 does not appear under $p$. Whether too low and the paper did not get its due impression on the type, or became "pie," your overseer will best know. It should be, $f = \frac{p}{8}$ ... (7).—TUBAL-KAIN.

[56346.]—**Sellers' Screw Thread.** — Since writing you, I find two correspondents have replied to this. With all due respect to them, I do not believe they are right. I gave you my authority, and could, if need be, supply a copy of the whole in a tabular form, as published by John W. Nystrom in his "Pocket Book for Mechanics." If we take the principle laid down by these two correspondents and simplify it, I believe they, as well as you, will see its fallacy. All dimensions being inches $p = \frac{d + ·25}{10}$ where $p$ is the pitch in inches, $d$ the diameter in inches; $t$ = number of threads per inch. By Nystrom's table, 6in. diameter has 2¼ threads per inch, using $\frac{10}{d + ·25}$, 6 becomes $\frac{10}{6 + ·25}$ = 1·60 thread per inch. $\frac{10}{5 + ·25}$ = 1·905 per inch, by table 2½ per inch for 5in. diameter; for 4in. $\frac{10}{4 + ·25}$ = 2·35 per inch, and by table 3 per inch for 3in. $\frac{10}{3 + ·25}$ = 8·175 per inch, and by table 3½ per inch.—TUBAL-KAIN.

[56353.]—**Planetarium.**—I here give the number of teeth to wheels for the above (I have copied them from an old work) that I think will answer inquiry. I have made a section and plan, partly by copy and partly worked out, but fear it will take up too much room for the E.M.; but will write you if you give your address—at any rate, I will give the numbers below:

| | Days of Orbit. | Proportion of Teeth in Wheels. A | B | |
|---|---|---|---|---|
| 365·25 | 88· | 83 : | 20 | Mercury |
| | 224·7 | 52 : | 32 | Venus |
| | 365·25 | 50 : | 50 | Earth |
| | 686·9 | 40 : | 75 | Mars |
| | 4332·5 | 7 : | 83 | Jupiter |
| | 10759 3 | 5 : | 148 | Saturn |

The above numbers on wheels, under A, are to be fixed to spindle running through them; those under B on hollow spindles.—W. H. ELPHICK, New Cross.

[56358.]—**Chronic Cold.**—With a large camel's hair brush lubricate freely the interior of the nostrils with fresh olive oil, at the same time sniffing it up until it gets well drawn into the throat. Do this many times a day. At first a little difficulty may be found as to inserting the brush as far as it should pass, both from a slight irritation it may at first produce, and also from nervousness. I have found this application for many years a most useful remedy against hay fever and the dust in summer in travelling by rail or road.—K. L. E.

[56375.]—**Microscopical.**—Hartzell's method: Spread a small quantity on a slide as thinly and evenly as possible, and allow to dry. Then pass slowly several times through Bunsen or spirit flame, and apply two or three drops of the following fuchsin solution: Carbolic acid, 15 minims, dissolved in distilled water, ½oz.; saturated alcoholic solution of fuchsin, ½dr. Allow stain to remain on sputum from three to five minutes. Wash slide thoroughly in distilled water to remove excess of fuchsin, and then completely decolourise in a saturated solution of oxalic acid. Thoroughly wash again in distilled water, and allow to dry. Mount in glycerin or balsam. With a power of 500 or 600, the bacilli will appear as brilliant red rods on an uncoloured ground.—W. J. ABEL, B.A., &c.

[56379.]—**Bichromate Battery for Lighting.**—TO MESSRS. "ACCUMULATOR" AND "BOBADIL."—I passed over the question as to liquid-proof separate cells for this reason—that if you can get the liquid in the bichromate battery to circulate through the cells, the circulation prevents the battery from polarising so quickly as it would otherwise do. But since you now intend using 10 earthenware jars, no more need be said on this point. The size of your carbons and zincs will do; but the latter should be ⅛in. thick, and if you use two carbons for each zinc, apart from their size altogether, the E.M.F. of the battery will be increased. You can get a 10 c.p. Swan lamp of 10 volts, of which fact Mr. J. Kean seems to be unaware when he states in last week's reply that 25 volts are required. I have used 10 c.p. lamps of 14 volts by other makers. To prepare the solution dissolve bichromate of potash in hot water, in the proportion of 2oz. of bichromate to one pint of water. When cold add about 2oz. of sulphuric acid. The addition of the acid will generate heat; but when the solution is again cold it is ready for use. A more convenient preparation is to use what is known as "Crystals for the bichromate battery," which is prepared by dissolving 1oz. of the crystals in 4oz. of water, and the solution is at once ready for use. Your experiment is certainly a doubtful one, and not only so, but troublesome and expensive, as most experiments are in the direction of producing electric light by batteries.—BOBADIL.

[56387.]—**Medical Coil.**—Many thanks to "C. D. R." for his reply. The cell I use is 4 zincs and 16 carbons, and I connect it to the usual coil, and apply the fluid to different parts of the body for the relief of rheumatism. Will "C. D. R." please say if I can charge with the bichromate of potash and sulphuric acid in this case?—D. W. G.

[56391.]—**Haydon's Cutter Bar.**—I am now preparing for the pages of the ENGLISH MECHANIC a full account of the principles involved, mode of construction, and of grinding the cutters, and this will appear almost immediately, and will answer the queries of "Bellicose" better than a short letter can do.—O. J. L.

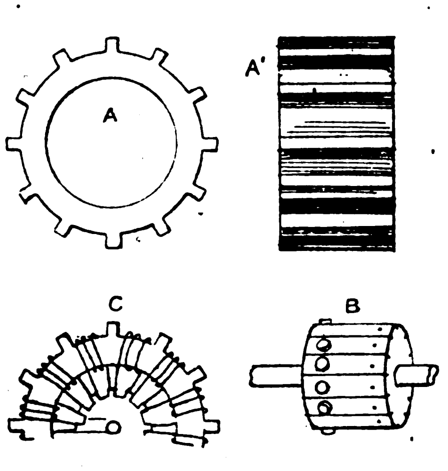
[56400.]—**Harmonium.**—I must apologise to the readers of "Ours" for having unintentionally made an error in my quotations of prices for certain fittings for a harmonium. The price of a set of reeds (five octaves) is 10s. 6d., and not 6s. 6d. as stated on p. 199. A really good pan for one row of reeds of 61 notes would cost between 8s. and 9s. Four shillings would be the price of a pine pan for four octaves, and 12s. 6d. about the lowest price for a four-octave keyboard. A five-octave keyboard would cost from 16s. to 25s. The price charged for the various fittings of the harmonium depends on the quality of the material used, and also the care bestowed in the manufacture of them. In an early volume I was found fault with because I stated that a set of reeds would cost 18s., which was a price frequently charged by a local dealer in harmonium fittings. Since that time I have had a great number of opportunities of discovering that from 20s. to 25s. is charged for a set of reeds by some dealers. In such cases as these quality and good profits have to be taken into consideration; and if we purchase a set of reeds of medium quality from a dealer in such articles for the amount of 10s. 6d., I do not consider that there is any room to complain. I still retain my unalterable opinion that 18s. is a very moderate charge for a set of reeds of good quality.—G. FRYER.

[56417.]—**Dynamo.**—TO MR. BOTTONE.—Wrongly connected. Connect one field-magnet wire to one binding-screw for outer circuit; the other field-magnet wire must connect to one of the brushes, and the other brush must make connection by means of a wire or copper strip with a second binding-screw, which forms the other terminal for outer circuit. Hence the flow of the current is from armature to one brush, from this brush right through the coils of the field-magnet, from the field-magnet to the external circuit (lamps, &c.), back to second brush and armature again.—S. BOTTONE.

[56418.]—**Gramme Dynamo.**—The insulation on the armature has broken down at some point; hence its resistance is much less than it was before. Therefore the resistance of the fields is much higher in proportion than it ought to be. By putting a wire across, sufficient current passes to magnetise the fields; hence you can get a light. Remedy: re-wind the armature.—S. BOTTONE.

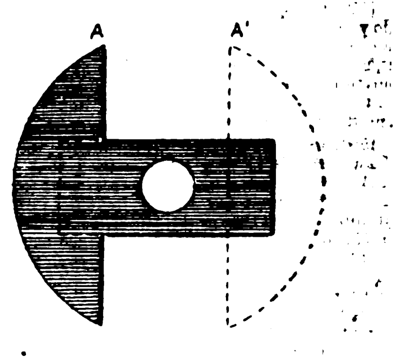
[56421.]—**Bichromate and Hydrochloric Acid with Platinum.**—Not advisable to risk it. Chlorine is sometimes evolved if the solution heats. —S. BOTTONE.

[56427.]—**Armature (Gramme).**—The best form for a small machine is the one figured in the annexed cut, in which A is an annealed cast-iron ring 3in. in diameter, with twelve teeth ½in. high round the periphery, the width is 2in., as shown at A¹. The commutator consists of a boxwood cylinder about 1½in. long by 1in. in diameter, B, around which are fastened, by screws at one end and pins at the other, twelve brass slips, not touching each other. The cylinder is mounted on a spindle, and care must be taken that neither screws nor pins reach through the wood to the spindle, or else short circuiting will take place. To the spindle or shaft is also keyed a wooden boss, to which the mounted ring is cemented. A ring this size will require about 1lb. of No. 20 silk-covered wire to wind it; each section is wound separately, and will take about 1¼oz. of wire. The end of each coil is carried to the commutator screw just under it, and from this same screw starts the beginning of the next coil, and so on (see C), so that the wire is really continuous around the ring; the field magnets, if wound in series, will require about 4½lb. of No. 16 cotton covered. When finished, this will light easily six 5-candle lamps without getting hot.—S. BOTTONE.



[56434.]—**Pure Woollen Material.**—If cloth is adulterated with cotton, that is easily detected by untwisting a few threads, or by applying a hot iron to a small portion, only enough to burn the face; then scrape it. The cotton will show itself, as it does not burn so readily as wool. Shoddy is more difficult to detect, as it is worked up with good wool; but if a large quantity is used, there is mostly sure to be cotton one way to give it strength. Shoddy cloth has the touch of a dirty carpet. Cotswold wool is largely used for making blankets, being long and strong in fibre.—VERAX.

[56442.]—**Laminated Armature.**—Annexed is half-size sketch of the punchings required to make a laminated armature. The punchings are in the shape of a T with a rounded top; these are strung on a shaft, which has a shoulder at one end and a screw at the other, and when the entire number is got on (about 100) the whole is tightened up by means of a nut. In putting on the shaft, place first A with the rounded portion to the left, then A' with the rounded portion to the right, and so on to the top. Mind, this is a patent of Mr. H. Jones's. the thickness of iron for a 3in. armature would be about $\frac{1}{10}$th of an inch, the entire length about 10in. The laminations are kept sufficiently apart by being laid odd and even, as described above. No boss is required.—S. BOTTONE.



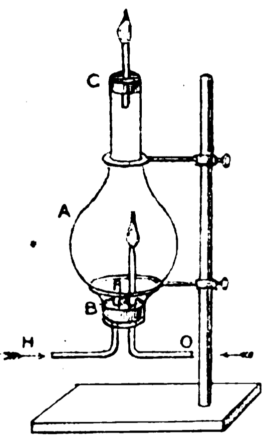
[56446.]—**Cement for Rain-Water Pipe.**—Perhaps the following will suit:—3 parts finely-ground litharge, 3 parts of clean white sand, 3 parts of plaster of Paris, and 1 part of finely-ground resin. Mix well while dry, and make into a putty with boiled linseed oil, to which a little driers has been added. Beat mixture well and stand for a few hours before using. This makes a strong and durable cement for fresh or salt waters.—A. R., King's College.

[56451.]—**Preparation of Sodium.**—The clay plugging which fits when cold does not fit when hot; besides, sodium vapour acts on clay, being thereby reconverted in sodic oxide.—S. BOTTONE.

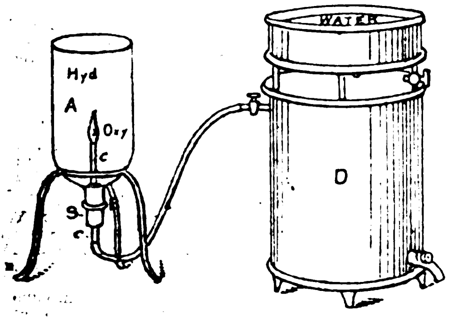
[56451.]—**Preparation of Sodium.**—Did "Perplexed" dry his sodium carbonate and finely powder his charcoal and chalk, and thoroughly mix before making the experiment, and was the clay plug perfectly tight? If so, I don't see why the experiment should fail. I would advise "Perplexed" to try the experiment once more according to the following directions: Well dry your sodium carbonate (7 parts when dry) and intimately mix with 2 parts of finely powdered charcoal, and 1 part of chalk (also finely powdered); make the whole into a paste with oil and transfer to a crucible (if you do not possess such an article, an old iron pot or vessel will do), and apply heat until the mass becomes partly fused (the object being to carbonise the oil). When this happens, transfer the fused mass to your apparatus and apply a moderate heat at first, gradually increasing until a white heat is obtained, when, if these instructions have been followed, sodium ought to be found in the naphtha. Please report progress—R. FORREST, St. Helen's.

[56456.]—**Strad. Model Violin.**—I regret I cannot give the thickness of Stradivarius violins; they, of course, vary with the density of wood. If you make yours one-fifth at the thickest part of back, reducing gradually to one-tenth at the ribs, and make the belly one-eighth all over, you will not be very far wrong.—T. LISLE.

[56459.]—**Burning Oxygen in Hydrogen.**—I have seen this experiment performed with the following simple apparatus:—A is an ordinary lamp chimney, supported in a ring stand. Two corks are fitted, one at each end. B is bored with two holes, into which are fitted bent glass tubes. The tube O is furnished with a jet. The cork C is also fitted with a jet. The apparatus is first filled with hydrogen by means of the tube H, C being closed up. When the globe is full of hydrogen, B must be withdrawn, and the oxygen or air tube O lighted. B must be then replaced, and the jet C' lighted, serving to carry off excess of hydrogen. There may be a little difficulty in getting O to light at first; but when this is managed, the oxygen burns easily in the hydrogen.—T. H. L.



[56459.]—**Burning Oxygen in Hydrogen.**—The best way, I think, to show that oxygen burns in hydrogen is as follows:—A is a large jar containing hydrogen. If the gas be inflamed at the mouth B, and the glass tube C delivering the oxygen from the gas-holder D be pushed through the gas burning at B, the flame will follow the end of tube on its way up into the jar, and by putting the cock into the neck of jar the burning hydrogen will be extinguished, but the flame within the jar will continue to burn where the oxygen gas meets with the hydrogen. Instead of the gas-holder D, which may not be procurable, a big bladder filled with oxygen with a weight upon it will answer the same purpose. In much the same way air may be made to burn in an atmosphere of coal-gas.—Combustion.



[56463.]—**Vertical Boiler.**—To "Invicta."—Very much must depend on your being able to do a little boiler-making. If you have a vertical of the usual type, I would suggest you should make it as follows:—Shell plate, ¼in. thick; height, 24in.; diam., 8in., riveted-up seam; firebox, 6in. diam., 15in. high—the bottom of firebox riveted to outer shell by flanging out the firebox round the bottom, or by the use of a wrought-iron ring, through which the rivets would pass. I prefer the latter for my own use somewhat, as the water space is not contracted round the bottom of firebox, and the plates do not need so much working and flanging. Funnel should be 2in. outside diam., and may be best secured by screwing both ends of a piece of steam tube, and by using lock nuts each side of the shell and firebox plates where the tube comes through. You will also want a fire door. This should be oval, size 2in. by 3in., with a similar wrought iron ring through, which would pass the rivets, holding all together. The funnel should be of larger size, so that it just slips over the 2in. tube; and if it is not carried into another chimney, should be at least 4ft. long. A boiler of the size I mention will give you plenty of steam for your engine at, say, 30lb. to 40lb. pressure; and if the exhaust is taken into the funnel to help the draught, it will still further increase the steam producing power. Do not forget an efficient safety-valve having, say, a clear aperture of ¾in.; also a water-gauge, and, if possible, a steam-gauge, and you will have an efficient and reliable generator which will fulfil the conditions you very reasonably lay down in your query.—Invicta.

[56469.]—**Skrivanoff's Dry Battery.**—To "Bobadil."—Not so fast Mr. "Experimenter." My reply can scarcely be called a repetition of "Starlight's" words, as I was not aware of his reply in the pages of "Ours," and had I been aware of it, as I am now, I should have referred the gentleman who asked the query to "Starlight's" page and number; but, apart from this, you will know that where two replies are given for constructing the same battery, in which the proportions must be exact, and never vary, both replies cannot but be substantially the same. Nor can the one be called a repetition of the other; but their sameness affords another example of the affinity which sometimes exists between two great minds. Your query belies your name, as you might have tried boiling the "substances" in a liquid, with which all "experimenters" are more or less familiar—viz., water, and using no more of it than will saturate them well.—Bobadil.

[56470.]—**Fitting Fusee Chain.**—"Nomen" may dispense with chain by the adoption of gut of the proper thickness to fit the channels of the fusee. Should he find any difficulty in making the ends secure, a little study before operation may prove a sufficient safeguard against ultimate trouble. After securing one end to the fusee attach the other to M.S. barrel; now wind up the gut by turning the M.S. barrel arbor with key or pliers, place on ratchet wheel, let click fall into tooth of same, press the click with one hand, and with the other give a turn more of the arbor: this secures the gut on barrel; wind up, coaxing the gut into fusee channels.—Fred. Hunt, Widnes-road, Widnes.

[56472.]—**Slide Valve, &c.**—I have so little time at my disposal this week that I am unable to set out as I should like a diagram, but let your slide valve be as follows: Height 1⅜in., length 1¾in., exhaust port in it ⅜in. long by 1⅜in. high, travel of valve 9/16in.; therefore the throw of the eccentric must be 9/32in. The ports are none too large, especially the exhaust, and I should have liked wider bars; for 300 a minute the ports are small; in fact, the power at that speed must, in great part, depend on the internal resistance. But you must not expect a great amount from so small a cylinder. The piston area is but about 3¼ square inches; so that in practice you might expect, perhaps, a man-power from it; theoretically, the speed and pressure would give you more than I name. But do not expect much as, practically, you won't get it. In theory it would come out at about ¼-horse; but, at 300 a minute, with the small area ports you would never get anything like 80lb. on the piston.—Invicta.

[56473.]—**Corn Drill.**—I see no very great difficulty in this. Possibly some of my brother contributors will at once deal with the query as the result of a practical and actual machine; if not, I will give the querist a plan I have in mind how it can be done.—Invicta.

[56476.]—**Incandescent Lamps.**—Because, when the air is admitted, the incandescent carbon instantly combines with the oxygen in the air to form carbonic anhydride, thus—$C_2 + 2O_2 = 2CO_2$. As long as the glass is not broken, the filament continues to glow, because, there not being any air in the globe, it cannot combine with it to form $CO_2$.—R. A. R. Bennett.

[56476.]—**Incandescent Lamps.**—What makes a piece of hot coal or coke burn when exposed to the air? The oxygen gas contained by the air. In precisely the same way the carbon filament raised to nearly a white heat by the passage of the current, cannot burn so long as no air is in the bulb; but directly the bulb is broken the air rushes in, the carbon finds the necessary oxygen, with which it immediately combines, forming carbon dioxide.—S. Bottone.

[56476.]—**Incandescent Lamps.**—To preserve incandescent carbon from chemical change, it must be hermetically sealed in vacuo, or in a globe containing a dry gas incapable of entering into chemical combination with the carbon, such as nitrogen, hydrogen, or hydro-carbon; if there be a trace of oxygen or other gas or vapour present, chemical change is the result. The oxygen having a great affinity for heated carbon, combines with it, and the dissociated carbon atoms are deposited on the inner surface of the globe. It follows that if the glass of an incandescent lamp is fractured, the air instantly rushes in, and its oxygen tears asunder the carbon particles composing the filament, and its destruction is the result.—H. H. Bales.

[56477.]—**Action of Glucose on Fehling's Solution.**—One molecule of glucose is said to be able to reduce five molecules of cupric sulphate, precipitating two and a half molecules of cuprous oxide; and the change is used as a method of estimating glucose. The exact reaction which takes place does not seem to be known, but it is very complicated, resulting, according to Claus, in the production of acetic, tartronic, formic, and various other acids, together with some kind of gum. It may be added that Soxhlet disputes the accuracy of the method, maintaining that the reducing power is greater in a strong solution than in a weak one.—Wm. John Grey, F.C.S., Analytical Chemist, Newcastle-upon-Tyne.

[56481.]—**Diameter of Tube.**—This seems rather a difficult question to answer directly; but, taking the weight of the tube and platform together at 7cwt., or ½cwt. per foot run, the area of the immersed part of the cross-section of the tube must be about 130 square inches, or 135 square inches for 6cwt. platform, and 1½cwt. tube. A diameter of 16½in., immersed 10in., will give about 135 square inches of immersed cross-section, leaving 6½in. above water line. But the whole thing would have no stability, and the platform (unless buoyant in itself) would very soon be below, instead of above, the water-line.—J. S. C.

[56484.]—**Varnished Wall-Paper.**—Will "Virago" try the effect of a piece of rag just moistened with the "paraffin oil" she burns in her lamps?—Nun. Dor.

[56485.]—**Model Boat.**—You may pretty easily do as you say. The blind laths are usually nice, clean, straight-grained stuff. As to sizes, I should myself never use wider laths than 1in., as the narrower they are the more flexible and easily bent to the run of the lines. Next you ask as to the overlap. If you do not know, I may tell you that boats are built in two ways, either clinker or carvel. The first is when the planks overlap; the second, and by far the best, is where the planks abut edge to edge. For a model of a steamer or yacht by no means use the clinker form. I have tried in times past both plans; but found the carvel-built boat by far the easiest. Not only so, but the stopping of the joints or seams is far easier. I fasten mine with shoemaker's brads, as having neat heads, and as with wire nails, they hold until further orders. I always use instead of ribs, bulkheads of hardish wood, say elm, or even pitch-pine. If these are objectionable as interfering with the engines, boiler, or other fittings, they are easily cut away, leaving still a stout rib firmly attached to and strengthening the planking. For a 4ft. boat I should use seven bulkheads; besides these, it is advantageous to use bent ribs of ash, steamed and bent to the curve of the planking. A good section for these is, in my opinion, ¼in. by 1in. The keel, stem and stern post, I like of either ash or elm. Knees of the same material are useful to stiffen and keep in place the planking at the bow as well as the overhang of the stern.—Invicta.

[56491.]—**Long-Distance Electro-Magnet.**—I should advise "W. A. G." to use his electro-magnet as a relay to switch on a local current of greater strength, which, being sent through a larger magnet, would be much more powerful. He can get any strength desired in this way. Had he mentioned the purpose for which it is needed, we should be better able to advise.—H. H. Bales.

[56495.]—**Feeding Bottle.**—If Mr. Morgan Thomas will use the best made black teat, with leech-bite incisions, the trouble will be remedied, although it is rather more difficult for the child to get the milk.—W. F. Harold.

[56495.]—**Feeding Bottle.**—We were troubled with the same inconvenience of which Morgan Thomas complains; but found a remedy in putting the bottle rather far down between the side of the cot and the bed. The shorter leg of the siphon being thus in the baby's mouth, it required some little suck to get the milk (which was good for the child's constitution), and when she ceased to draw the contents of the tube flowed back again into the bottle.—J. L. D.

[56499.]—**Electrical.**—A similar question was answered in the "E. M." a few months ago, a diagram being then given showing that you can ring in both directions as desired, with ordinary pushes and one battery, by the use of three wires instead of the usual two. Where the distance between the two stations is not great, this arrangement is more economical and simple than using key pushes and two batteries; but for anything over quarter of a mile, the cost of the additional line wire would place the balance of expense on the opposite side.—R. T. Lewis.

[56501.]—**Dynamo.**—Cogs and ring are in one piece; wire wound in channels between cogs; made of annealed cast iron. There are as many sections in commutator as there are channels in armature. The end of one coil coming from armature fastens to one section of commutator, and forms the beginning of the next coil, and so on all round. Would work well, but less E.M.F. and less R.—S. Bottone.

[56502.]—**Faulty Dynamo.**—To Mr. Bottone.—Reason of failure: Resistance of wire on fields insufficient for that on armature, when used as a shunt machine. A shunt machine will take from 60 to 100 times the resistance of F.M. to that on the armature. Calling field magnets M, resistance R, armature A, and external resistance X, then the best shunt arrangement is $RM = \frac{RX^2}{RA}$.—S. BOTTONE.

[56504.]—**Hand Dynamo.**—To MR. BOTTONE.—The same leather bands that are used to drive sewing machines. I always drive with straight band, and have no difficulty in getting up a speed of 3,000 revs. per minute. As to joining, cut the band a trifle shorter than will loosely fit the wheels; make a hole in each extremity with a cobbler's awl, insert a short length of No. 16 hard iron wire, previously bent into the shape of a flat U, and then hammer the ends of the wire inwards until they do not protrude beyond the level of the band.—S. BOTTONE.

[56505.]—**Flow of Gas in Pipes.**—The quantity of gas delivered by pipes of a given diameter is found by the formula—

$$Q = 1,350\ d^2 \sqrt{\frac{h\ d}{s\ l}},$$

which is plain enough to any "Young Gas Man" who will take the trouble to use his brains. Multiply the pressure in inches of water ($h$) by the diameter of the pipe in inches, and divide the product by the specific gravity of the gas multiplied by the length of the pipe in yards ($s\ l$). Extract the square root of the quotient so found, and multiply it by 1,350 multiplied by the square of the diameter of the pipe in inches ($d^2$), and you will have the number of cubic feet (Q) discharged in one hour. The querist can take the specific gravity of the gas at 0·4, which will be sufficiently accurate for all practical purposes. A difference of pressure of 1in.—that is, from 1in. to 2in.—will increase the delivery by, roughly, one half.—NUN. DOR.

[56505.]—**Gas.**—The following may be of use. Mr. Sugg, in "The Domestic Uses of Coal Gas," gives the following table of flow of gas per hour through a 30ft. length of pipe:—

| | | | Diam. of Pipe. | | |
|---|---|---|---|---|---|
| Pressure in tenths. | | | ½ | ¾ | 1 |
| 2 | ,, | .... | 53 | 147 | 302 c.f. |
| 4 | ,, | .... | 75 | 207 | 426 |
| 6 | ,, | .... | 92 | 254 | 522 |
| 8 | ,, | .... | 106 | 293 | 603 |
| 10 | ,, | .... | 119 | 328 | 675 |

The following is from "Clegg on Coal Gas":—Discharge of gas in c.f. per hour through ¾-pipe at different pressures (s.g. of the gas estimated at ·4, air being 1)—

| | Length of pipe (yards). | | | |
|---|---|---|---|---|
| | 10 | 20 | 30 | 50 |
| Gas delivered with | | | | |
| ·1 press... | 104 3 | 73·8 | 60·0 | 46·6 |
| ,, ·2 ,, .. | 147·5 | 104·3 | 84·9 | 65·8 |
| ,, ·3 ,, .. | ,, | ,, | 104·3 | 80 9 |
| ,, ·4 ,, ... | ,, | ,, | ,, | 93·2 |

—GAS CONSUMER.

## UNANSWERED QUERIES.

*The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.*

Since our last, "Glatton" has replied to 55962.

55972. Glass Working by Lamp, p. 569.

## QUERIES.

[56507.]—**Engine Query.**—Will any of your readers kindly inform me how it is that, having attached a McNaught indicator to the cylinder of a beam engine (h.p. condensing) that was wasting steam, instead of a pressure it showed a vacuum of from 5lb. to 11lb., although a pressure in boiler of 12lb. of steam? I may remark that the indicator was attached to a tallow cup on top cover, which is cored hollow, and at bottom to drain cock which comes in the space between bottom of piston and cylinder bottom.—AMATEUR.

[56508.]—**Royal Engineers.**—To COL. ROSS, "GARRISON GUNNER," AND OTHERS.—I am an electrical engineer. I should like to know if I am suited for the R.E., or any division of the service where a thorough knowledge of electricity, engineering, and chemistry would be required. I have a splendid constitution and am 5ft. 10½in. tall, 13st. weight (normally 12), know my drill well, though I am not a volunteer. I have travelled in almost every portion of the globe. I should like to know the pay, duty, and chance of raising myself from out of the ranks, also where to apply? What is the extreme age they enlist one? I am well connected, and shall ultimately come into considerable possessions, though I am, for the present, placed in very straitened circumstances; am also a University man. I have been a constant reader of the "E.M." for nine years, and have answered, as far as I could, very many questions under a certain well known n.d.p. I should feel extremely grateful to the gentlemen named, or any others for kind advice.—F. L. B., Kew.

[56509.]—**Cheap Gas.**—To "INVICTA."—In answer to "Glatton's" query regarding cheap gas, you volunteer to give him private information, by way of the Address Column, respecting this gas; and also as to some recent improvements in your apparatus. Now this is the very thing I want, having a small gas-engine, but no gas to drive it. If you will kindly communicate with me, respecting this gas apparatus, you will find my address in the "E.M." of April 10, it having been inserted in order to attract your notice, but you seem to have overlooked it.—W. J. BARRY.

[56510.]—**Extra Strong Magnets.**—I lately noticed an advertisement of, "Magnets made very much stronger than the ordinary ones, by a new process, so as to lift from ten to fifteen times their own weight." Can anyone inform me what the "new process" is? I have made a magnet, horseshoe, of the best cast steel, weighing 3lb., as hard as fire and water will make it; but cannot get it to lift more than 6lb., although the armature fits the poles as a slide-valve its face.—ZINCI SULPHAS.

[56511.]—**Mathematical Astronomy.**—Will "F.R.A.S." or some other of our well informed astronomical contributors, kindly say what course of mathematics, pure and applied, one should read, in order to understand the higher parts of astronomical science? Any information as to list of works, and how to proceed, will be esteemed by—ANOTHER AMATEUR.

[56512.]—**Diamond Tools.**—Will Mr. Wenham kindly describe the ingenious sliding or dividing-frame, by means of which a little piece of carbonado is used for dressing millstones?—T. W.

[56513.]—**Chemical.**—Hydrogen peroxide, or rather its watery solution, is made by decomposing $BaO_2$ with HCl, or clear suitable acid and water. The $BaO_2$ is made by oxydising Ba O, with one third its weight of $KClO_3$, being somewhat in excess of the amount theoretically required, the excess of oxygen passing off, the product being really $BaO_2 + KCl$. In practical work, about 4lb. of this mixture is required for 1gal. of $H_2O_2$ solution of 12 volumes. I want to know, when testing the $H_2O_2$, with potassium bichromate, for its volume, whether the whole of the oxygen given off is derived from the $H_2O_2$ or partly from the bichromate; in other words, whether the $H_2O_2$, of 12 volumes does not only contain six times its volume of oxygen? Also what quantity of $H_2O_2$, of 12 volumes, as above, can theoretically be produced from the 4lb. of the $BaO_2 + KCl$?—HYDROGEN PEROXIDE.

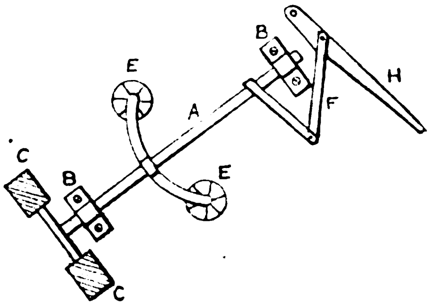
[56514.]—**Chemical.**—In bleaching ostrich feathers, I use hydrogen peroxide, and I find it is of two different qualities; the difference appearing only on the addition of solution of ammonia. One kind remains transparent on the addition of ammonia, the oxygen passing off somewhat quickly; the other kind becomes opaque like milk and water, curdles almost to the consistence of jelly; on the addition of ammonia; the curdled matter gradually separates, leaving the rest transparent, but the oxygen passes off slowly. Will some practical chemist kindly inform me what impurity or substance is dissolved in the hydrogen peroxide, to cause this change with ammonia solution?—OSTRICH FEATHER BLEACHER.

[56515.]—**Lead Burning.**—I am about burning on some lead pieces, to cover fracture of a large chemical chamber, which is now full of acid, and find a great difficulty in doing so, owing to the acid continually running through the open space. Is there anything I could bed against it, while performing the work, or should I get the chamber emptied before commencing, which of course is very undesirable if it can be done otherwise? A few hints would greatly oblige.—A. B. C.

[56516.]—**Disabled Marine Engine.**—What should be done to bring a ship into port with one engine, the low-pressure having broken down; and what if the high-pressure engine broke down, the low-pressure remaining intact and is there any book on remedies for breakdowns at sea?—VALVE.

[56517.]—**Microscope Construction.**—I have read with much pleasure, the promise of "Rob. Crus." (24143, on page 109) to give complete instructions in the grinding and fitting of glasswork for the microscope. I have in process of construction, a full sized stand of the Jackson-Lister type, with mechanical stage, substage, &c. It is my intention, as soon as the stand is completed, to attempt the glasswork, such as achromatic condenser, paraboloid, and the lower power objectives. Now, I am sure the instructions "Rob. Crus" proposes to give, would prove most acceptable to very many readers. No doubt an amateur's first attempt at achromatic lens construction, will be a failure; but amateurs, as a rule, are not easily discouraged by failure, and generally succeed in the end. I have been a subscriber of "Ours" for some years, but I have not seen any complete working instructions. When my stand is completed, I shall be pleased to give my way of constructing it in an ordinary lathe, with a fair amount of ingenuity and mechanical skill.—J. J. B.

[56518.]—**Organ Building.**—To MR. FRYER.—As I am about to build a small chamber organ of five or six stops, should feel very much obliged if you could spare time to answer these few questions:—Will these be the most suitable stops?—Two 8ft., two 4ft., one 2ft., stops, viz., stopped diapason (wood) CC to F in alto. Open diapason, C to F in alto (wood). The lowest octave of stopped diapason to draw separately, so as to answer for both. Flute, CC (4ft.) to F in alto (paper); dulciana, CC, 4ft. to F in alto (metal) and one, 2ft. (in metal or paper)? Also, as I should like to make the dulciana the speaking front; can I make the shorter pipes (say the 2ft. ones) 2ft. 6in. long, and cut open at back, so as to make a cover for the back pipes? Would you also tell me the best scale to make the stops to? The stopped diapason will be 3½in. by 4in. deep. Should like to run the 8ft. and 4in. stops an octave higher, and have a coupler. The wind will be 2in. Will it not be best to have two feeders to blow by foot and by hand, according to this plan? A, rocking shaft of gas barrel; BB, bearings; CC, treadle; EE, two wheels on curved arms to work under feeders; F, arms to connect to handle; H, blower handle when required. The lowest octave of stopped diapason, and of the flute; shall put on lower soundboard at back (or could I use conveyancing tubes)? The lowest octave of dulciana should have along one side, and of the open diapason on the other, and inclose them all in the case. If you could suggest any improvement to the general construction of the organ, should be obliged. Is it necessary to have iron bits for soldering the metal pipes—if so, why?—ANXIOUS.



[56519.]—**Chemical.**—What is the chemical action of soap on (1) boiling water, (2) on cold water, (3) and the action of soap on cold water when a quantity of ordinary shaving soap has been first added?—C. W.

[56520.]—**Gasoline Generator.**—To T. F.—1. You kindly answered me about four months ago, that a gallon of gasoline would absorb 250 cubic feet of air. Can 250 cubic feet of gas be made by forcing that amount of air into a generator, which holds one gallon of gasoline? 2. I presume this 250ft of gas, so made, would require about five times as much common air to dilute it in the engine cylinder; if not, what proportion, about? 3. A Clerk six-h.p. gas-engine (cylinder, 7in. diameter, 12in. stroke) compresses the charge of coal gas to about 70lb. before ignition, the explosion gives a maximum pressure of 250lb., and an average pressure of 69lb. What do you think would be the maximum pressure of the above-mentioned gasoline gas, used in the same engine, and compressed to same amount, previous to ignition.—E. C.

[56521.]—**Jupiter.**—The o.g. of my telescope is 2¾in; is this too small to perceive the transit of Jupiter's satellites across the disc of the planet, the power I use being 100? What size of o g., and what power of eye-piece will enable me to witness this phenomenon with certainty and comfort?—E. B. F.

[56522.]—**Legal.**—A. has rendered some services to an English Co., for which a commission has been allowed him, but payment of said commission has been deferred until a certain date. The Co. is wound up before that date. Is there any difference to A.'s claims on account of this winding up? What course should he pursue now?—LEGAL.

[56523.]—**Finishing Silver-Plated Goods.**—Will "Goldsmith" please give the promised instructions how to finish silver-plated goods, after they leave the bath? and any other practical hints will greatly oblige.—LANTERN.

[56524.]—**To Mr. E. M. Nelson.**—Please describe the two lenses in Swift's £4 popular condenser; are they both made of same sort of glass, and non achromatic? Also the shape of the top lens, which appears to be somewhat peculiar? What do you think of turning it over, silvering the convex surface, and grinding off the apex? Which has most flint glass, a dry or immersion o.g.?—AN AMATEUR.

[56525.]—**Cyclist Tour in Scotland.**—Will some reader kindly say whether the roads in the district between Trossachs and Oban are good for cycling, and name a good road map of the district?—G. R.

[56526.]—**Stained Floors.**—A floor has been stained and varnished last year; being worn, it is desired to restain it, but on doing so the stain becomes patchy, not taking on top of varnish. What would be the simplest and cheapest way of obviating this?—E. C. OSWALD.

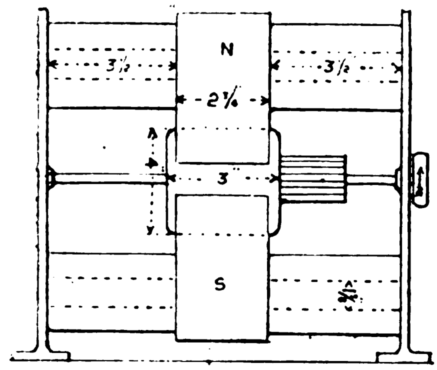
[56527.]—**Engine.**—To "INVICTA" OR "GLATTON." Will you please kindly help me a little? I am making pair of engines, 3in. bore and 4½in. stroke. I want to know the length of slide valve; this is the size of ports—Port ¼ $\frac{1}{32}$in.; bar between, ¼ $\frac{1}{32}$in.; exhaust port, ont to out of ports, 1½in.? Also say what power she will be with 60lb. of steam, running 140 revolutions per minute, driving a boat? Say how large a fan she will drive, and the pitch of same, and width of blades? How large a boiler would it take to steam her easily? I rather prefer the horizontal type of boilers. Say how it should be made to give best results, size of fireplace, and number of tubes, if any? Any information will greatly oblige.—C. L. L.

[56528.]—**Bending Box Spade Handle.**—Would some one kindly inform me the sort of machine used for bending box spade handles?—Box Handle.

[56529.]—**Legal.**—Would any of your legal correspondents kindly name one or two of the clearest and most comprehensive "Justice's Manuals or Guides"?—and oblige.—T. G. T.

[56530.]—**Pallet Holes for Harmonium.**—Will some of our harmonium friends kindly inform me the size of pallet holes for two rows of reeds, also size of holes for reeds, and if reeds will sound right if simply screwed on top of holes?—and if not, kindly state how they want fixing, and how the valves are opened in the American exhaust principle? Any details will be very acceptable, as I am about to add two more rows of reeds on my harmonium, and want to draw the wind through them.—Harmonica.

[56531.]—**Gramme Dynamo.**—I have just completed a Gramme dynamo but can get no satisfactory result therefrom. General arrangements and size may be seen from sketch. Side cheeks are of cast-iron, and pole pieces of malleable cast-iron, driven at a speed of 3,000 revolutions per minute. Can get no appreciable current. When coupled to another dynamo, it acts as a motor, although weakly, and, strange to say, if wires from dynamo are reversed, the direction of rotation is still the same in the driven machine. Armature consists of 16 segments of No. 18 S.W.G., and total wire, weight of 2lb. 2oz.; usual Gramme core (solid); wire on field-magnet, S.W.G., and total weight, 14lb. 4oz. Machine during experiment was coupled up in series throughout. Any suggestions to enable me to put it right, stating amount of current it should give, will oblige.—Vandee.



[56532.]—**Rates and Taxes.**—To Mr. Weatherfield and Others.—An answer to the following will greatly oblige. Last year I was assessed at £50, and paid on £40 for poor and boro' rates, and £50 for property and house duty, but this year I appealed against the poor rates, and now pay on £32 (net). What I want to know is, can I be made to pay the property and house duty on the old assment (£50) or only on the present gross assessment £40?—A. R. James.

[56533.]—**Pocket Telescope.**—I have a small pocket telescope, which has an achromatic ¾in. object-glass, and four other lenses: it opens to 16in., and having six draws, closes to 4in., it is powerful (for its size) and has fair definition, but seems to absorb a considerable amount of light. Is there any cheap expedient by means of which the light might be improved, without much detriment to the power and definition, especially the latter?—Devoniensis.

[56534.]—**Opera-Glasses.**—I notice that opera-glasses are spoken of as "power, four, seven, ten," &c., how is the power ascertained?—Devoniensis.

[56535.]—**Yellow Photographs.**—I have a number of photos which have turned yellow, but have not faded much. Is there any restorative process, and if so, will any kind reader give it?—Devoniensis.

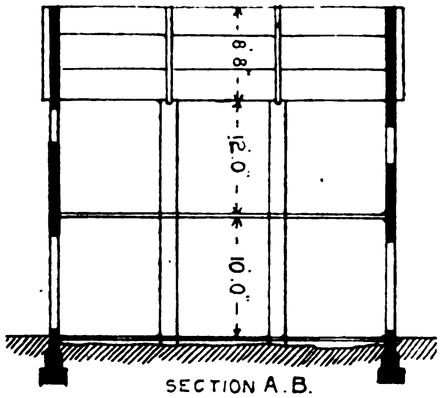
[56536.]—**Special Run.**—On the occasion of the Duke of Albany's death, the Prince of Wales came from Edge Hill to Euston in 3h. 40m., according to newspaper reports. Can any reader give details as to stops, running time, composition of train, &c., such as we have in the case of the noted runs of the Prince of Wales and the Lord Mayor, on the Great Northern a *few* years ago, and with which this North Western performance appears to compare favourably?—L. N. W.

[56537.]—**Railway Distance.**—What is actual distance (via. Crewe and Runcorn) between Lime-street and Euston? It is variously stated at 193½ miles, and 201½ miles.—L. N. W.

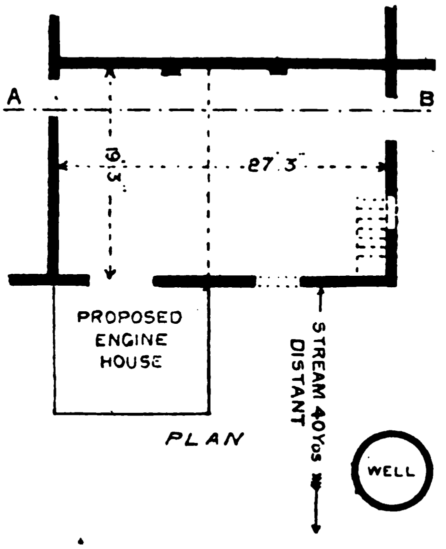
[56538.]—**Ink for Black Edged Note Paper.**—Can any kind reader tell me how to prepare the ink, or material used to black the edges of note paper, and how it is done?—Spot.

[56539.]—**Electric Lighting.**—I am desirous of fitting up the electric light in the sunk flat of our warehouse. In one corner there is a gas-engine driving our machinery, from which I hope to get sufficient spare power to drive the dynamo. The flat is at present lighted with 12 gas jets burning about 54 hours a week on an average, the cost being about £20 annually. I may mention that this flat is usually full of large piles of paper which will interfere with the proper diffusion of the light. Would any of "ours" be kind enough to enlighten me on the following points? 1st, What is the best system for electric lighting under these circumstances? 2nd, What number of lights would be required, and the power of each? 3rd, What size of dynamo would be required, and how much horse-power would be needed to drive it? 4th, Supposing I had sufficient spare power to drive the dynamo, what would the probable cost be of dynamo and lights, and also the annual charge necessary to maintain the lights in working order?—Enquiring Subscriber.

[56540.]—**Westinghouse Engine for Flour Mill.**—I am building a small flour mill, see plan and section, in connection with another establishment, and intend to use Ganz's roller mill, No. 21, capable of grinding daily say, 80 bushels of wheat. I would like to know the most suitable motor to employ. I intend to use a Cochrane's patent boiler of 160 square feet of heating surface and 80lb. working pressure. I have been told that there is little economy in small compound engines, say, of 10-h.p. nominal. Having regard to economy in coal consumption, and maintenance of engine, which of the following would be most suitable? 10 H.P. nominal compound engine; h.-pressure cylinder, 6½in. by 12in.; l-pressure cylinder, 10in. by 12in.; flywheel diameter, 5ft. 2in.; revolutions 180 per minute. A high-pressure expansive condensing engine, cylinder, 10in. by 20in., flywheel, 7ft. 1in., revolutions per minute 108. A Westinghouse engine, 18 horse-power, cylinder, 7in. by 7in., revolutions per minute, 375, piston speed, 437, flywheel 27in. diameter. Will some practical man give opinion on the above, or a better arrangement? A sketch of arrangement of shafting and requirements desirable, as I have no experience in the business, and I am where I can get no professional help. Are the sizes of engines and boiler suitable? There is a well about 20ft. from the building, 6ft. diameter and 9ft. deep, with about 6ft. of water in it. There is also a small rivulet 40yd. distant, the water of which is about 9 or 10ft. below the level of ground floor of mill. As far as I can understand, I prefer the Westinghouse engine, if it is suitable for mill work. Would like to know how the speed can be varied, and how slow can it be run? I should be glad to get any and all the information possible relative to the above.—Miller.



SECTION A. B.



[56541.]—**Experiments with Magnetic Machine.**—Will some fellow reader kindly tell me of a few experiments which we may perform with this instrument? Ours is a machine with multiplying wheels, which cause the armature of coiled wire to revolve rapidly before the poles of a large horseshoe magnet. It is used for medical purposes, but we are quite tired of the monotony of shocking our friends, and as a pleasant variety would like to now charm them with a few instructive experiments. Can we fire gunpowder with the machine, or show the electric light, or cause models to revolve?—Claudius.

[56542.]—**Staining Deal Floors.**—Would some reader kindly favour me with a good method of staining yellow deal floors subject to much foot traffic, such as corridors, &c. The doors and other woodwork are painted a darkish brown-colour, and walls buff in distemper. A very durable colour that would harmonise with the two colours named would be best, no doubt. Any information on this matter, as it is for an important building, would greatly oblige a 12 years' constant reader of the English Mechanic.—G. R.

[56543.]—**Carpenter Brake.**—Could Mr. Stretton or any other railway correspondent give a description of this brake? A friend, recently returned from Germany, informs me that it has been fitted to a great number of vehicles on one of the railways there. He says it is very similar in action and construction to the Westinghouse, and that it does away with the triple valve. Is this so?—G. Park.

[56544.]—**Coulomb or Weber.**—Wormell says, "The practical unit of quantity is 1-10th of the absolute unit, and is called the coulomb." Everett says, "The weber is 1-10 of the C.G.S. electro-magnetic unit of quantity." Is there any difference between them? If not, why the two names?—G. Park.

[56545.]—**Legal.**—Suppose a person was christened, say, John Henry Smith, who had been previously registered as John William Smith, which would be (legally) his correct name?—G. Park.

[56546.]—**Magnetic Moment.**—I should be much obliged for a clear definition of magnetic moment. I cannot understand Guthrie's definition at all. Everett (Deschanel) defines it as the "product of the line joining the two poles by the strength of either pole." What does this mean? By what units are the line and strength measured? How is the answer 300 obtained to this question: "A magnet, 1 decimetre in length, has poles of strength 3 units each, and is placed in a field of 10 dynes intensity. Required the magnetic moment?—G. Park.

[56547.]—**Geometrical.**—Can any correspondent help me to understand the following question in Todhunter's Euclid? It is among the Exercises in Euclid, at end of book, No. 570. "Four straight lines are drawn in a plane forming four triangles; show that the circumscribing circles of these triangles all pass through a common point?" Todhunter is usually so exact, but I quite fail to see how I can form four triangles with four straight lines.—J. C.

[56548.]—**Ferro-Prussiate Copies.**—Will any of your readers kindly inform me how it is that ferro prussiate copies of drawings, i.e., the white line on the blue ground, turn pale and become almost invisible if left for any time in a strong light? Also if anyone can tell me how to fix the copies so as to prevent the fading?—W. T. B.

[56549.]—**Bronzing Iron.**—Can any reader inform me how I can brass-bronze a quantity of small stamped round iron plates?—S. T.

[56550.]—**Sawing.**—I have been trying to saw some trees into planks, but do not get on well at all. We seem to get on all right for about 12in. and then it cuts hollow sometimes as much as ½in., and all the way on the twist, so they are not much use. Is it the fault of the saw or the men using it, and it is such hard work lifting the saw up? Any information I should be very thankful for.—Alabama.

[56551.]—**Wheelwrighting.**—To Mr. King.—I should be obliged if you or any other reader could tell me the best way to get old spokes out of knaves? I use hoops and wedges and sledge hammer, but I cannot draw them. Is there any machine for the purpose? Do let me know or any other way.—Alabama.

[56552.]—**Gas-Engine.**—To "R.A."—Will you please send full description, with sketch, of your gas-engine for small powers, as promised some time ago? I desire to build one at once of ½-h.p.—B. R. W.

[56553.]—**Gasoline Gas-Engine.**—Thanks to "Invicta." I have ordered the patents he mentions, but not living in England, they will be some time in reaching me. Will "Invicta" please give me dimensions of cylinder, diameter, and length of stroke, for ½-h.p., and if seamless mandrel drawn tubing 1-10in. thick would be strong enough for cylinder and suitable for.—Gasoline.

[56554.]—**Ordnance Factory, Enfield.**—Can any one tell me how many men are employed at the Ordnance Factory, Enfield?—Kappa.

[56555.]—**Professor Langley on the Solar Rays and the Atmosphere.**—Your last week's number contains a notice of Prof. Langley's lecture on the absorption of sunlight by our atmosphere, in which he showed that a great difference is observable in the solar spectrum taken at the foot of a high mountain and at its summit. How far is this change due to the difference of atmospheric density (to which Prof. Langley ascribes it), or to the effect of the difference of temperature (between the plain and the summit where the observations were taken) upon the prisms used in the experiment—a make referred to in a paper by Dr. Draper quoted in your last week's number? The obtaining of more heat from the solar beam, or from ordinary flames in a rare atmosphere as compared with a dense one, is surely opposed to previous experience.—R.

[56556.]—**Heating Surface in Vertical Boiler.**—Having finished the engine, I am about to make a boiler to suit. The engine is 3½ h.p. Will any kind reader tell me what heating surface I shall require in the firebox and tubes to make enough steam to feed the above, having a working pressure of 25lb. to the square inch?—A. J. Lawrence.

[56557.]—**Coefficient of Centrifugal Force.**—This expression occurs at page 212, of Richards's work on the Indicator, third edition. Its numerical value is given as ·000341. What does it mean?—Wm. John Grey, Analytical Chemist, Newcastle-upon-Tyne.

[56558.]—**Lincoln Cathedral.**—In "All the Year Round" for April 24th, 1875, there is a description of the above cathedral, in which it says:—"Singular paradox in stone"; "that architectural puzzle, the centenarian beam"; "a daring artifice of the old Gothic builders"; "a more magical and exquisite gauge and test-piece was never invented by human ingenuity." Will some of our architectural readers kindly describe, void of technicalities, the wonderful property of the said beam, and how it is constructed? Doubtless many have never heard of it, including your humble servant.—Gwent.

[56559.]—**A New Gum.**—*Chambers's Journal* for April 26th, 1878, gives an account of a newly discoverd gum "of a dark amber colour"; "can be moulded to any form"; "and on cooling becomes tough and strong"; "does not warp"; "and resists acids." Has the gum become a trade article yet, or has it died out for want of the characteristics described, or what? If to be obtained commercially, what is its name?—Gwent.

[56560.]—**Eight-inch Spark Induction Coil.** Would Mr. Earnest Haugh kindly tell me if he puts more than one disc of ebonite of thickness mentioned in a place on tube? Secondly, does he put paraffin wax in the bottom of each section, to keep spark from passing between disc and ebonite tube? Thirdly, in ordering sheet ebonite, does he get it ready cut in discs at 7s. per pound? Fourthly, does a small dynamo machine work coil as well as batteries?—Ross.

[56561.]—**Electric-Pen Battery.**—I use a four-cell Fuller's bichromate, to drive this pen, and find that it soon gets out of order. Can any one recommend me a better battery? Would the use of bichromate salt be advisable?—No Sig.

[56562.] — **Medical Battery.** — I want a good medical battery to give a current equal to a 12-cell Daniell. Have been recommended to fit up a 15 to 20 cell Leclanché, but fear it would not be constant enough. I want it to work one hour a day. Would the Becker-Muirhead be suitable?—if so, how should it be constructed?—No Sig.

[56563.]—**Medical Coil.**—In using a medical coil, how am I to distinguish between the positive and negative currents? I have a book on medical electricity, which repeatedly refers to the negative magnetic current, and I would like to know how to tell the difference.—No Sig.

[56564.]—**Pocket Battery.**—To Mr. J. E. Chaster.—I wish to make a pocket primary battery, to light, say, a 4·5 volt incandescent lamp. If you would give me the following particulars I should be extremely obliged:—Size and materials of plates; exciting solution, and number of cells to give required E.M.F. How would Skrivanoff's battery, mentioned in your reply 56244 do? From half to three-quarters of an hour's light would answer my purpose very well?—Centauri.

[56565.]—**Dynamo.**—I beg to thank Mr. Bottone for kindly answering query 56320, in No. 1048; but am I to understand it will take so long after the accumulator has been once formed? I shall make a dynamo with a Pacinotti ring armature, half the size given in Vol. XXXIX., if I can get one with cogs inside as well as outside. Is it necessary for the ring to be insulated from the spindle that turns it?—A reply will greatly oblige.—Microscopist.

[56566.]—**Iron Moulding.**—Would some correspondent please explain the difference between green-sand and dry-sand moulds, and to what class of work is each suited? Is there any difference in the composition of the sands, and what is the best composition for each?—Apprentice.

[56567.]—**Dark Room, Wooden Sink for.**—I am intending to fit up in my dark room, a table with small sink in one corner. I wish to make both impervious to water and chemicals. Can anyone give me instructions how to do this?—Hereward.

[56568.]—**Violin.**—Can any reader give me any information regarding violins by Thos. Kennedy, maker, No. 19, Princes-street, Westminster, 1809?—W. E. Toombs.

[56569.]—**Pressure of Boiler.**—Will "Boswell," or any other of our correspondents, show me the method used to get the bursting and working pressure of our boiler, which was made in 1870, and say whether 15 years is a reasonable time for a boiler to work at the pressure it was made for? The brand is Bowling iron. Length of boiler inside, 26ft. 10½in.; diameter of shell inside, 7ft. 1in.; thickness of shell plate, $\frac{7}{16}$in.; thickness of flue tubes, ⅝in.; diameter of fire-box, outside, 2ft. 9½in.; pitch of rivets shell, 2in.; pitch of rivets flue tubes, 2in.; Galloway tubes in each flue tube, 5in. diameter, 11in. at top, and 6in. at bottom. Hoping that someone will oblige in plain figures.—Sammy.

[56570.]—**Brazing.**—Will some reader inform me how to braze ⅜in. or ¼in. thick of copper or yellow metal with a gas blowpipe? I have a good bellows and gas, but no blowpipe—what blowpipe will suit me for the above purpose?—W. J., Llanelly.

[56571.]—**Electrical.**—Can anyone inform me the time in which a given quantity of water can be split up, or decomposed into its component parts of oxygen and hydrogen, by the use of four or five Grove or Bunsen cells, and the volume of the gases that are produced from a given quantity of water?—Witch.

[56572.]—**Lathe Mandrels.**—Perhaps some of our readers will be kind enough to tell me what advantage there is in the inverted loose cone which is found at the back end of some lathe mandrels, principally of the cheaper kind I believe. To me it appears that two cones on the mandrel itself, the back one smaller than the front, and lock nuts to take up wear is a much better plan. Will a mandrel of soft steel, unhardened, running in phosphor bronze, make a good job? I thought of having cones tapering from 1¼in. to 1in. in front, and from ⅞in. to ⅝in. in back, each cone being 1⅜in. long and their bearings 6in. apart. How would this work for a strong 3in. lathe? "Invicta," with his usual courtesy will probably oblige—A. L.

[56573.]—**Chronic Rheumatism.**— To "B.Sc., Plymouth."—Having read your answer to "Chronic Cold," I have ventured to write to you concerning myself. I have suffered some eight years from what has been termed chronic rheumatism of the nerves, and during that time have been quite unable to follow my usual occupation; but by the aid of plenty of flannel, and abstaining from all things likely to assist the complaint, I have seemed to stave off a deal of the pain until now and during the last winter, in which time it has seemed to have laid fresh hold of me. I ache with cold inwardly, at the same time am suffering from cold clamminess on the skin; cannot stir outside only on a still warm day, although I have persevered: it only results in fresh pains next day round loins, shoulders, face and legs, a bruised kind of feeling. I perspire profusely after after taking liquids hot or cold: am very thin and weak; my age is 58. Any advice you can kindly give me I shall esteem a great favour, trusting our Editor will kindly insert this for a—Many Years' Subscriber.

[56574.]—**Bearing Grease.**— Will one of your correspondents kindly give me, through the columns of the "E.M.", a recipe for making hot neck (bearing) grease, the price of which must not exceed 2½d. per lb.?—Inquisitor.

[56575.]—**Galvanometer.** — An astatic galvanometer is inclosed in a machine and entirely concealed from view. Will anyone kindly suggest a plan for telling when the needle deflects?—Jesse Budge.

[56576.]—**Insulators.**—Can any of "Ours" kindly inform me what substance is that which is put in with the bolts of insulators?—some kind of a cement it is.—Therma.

[56577.]—**Soap.**—Can any of your correspondents inform me if cotton seed oil is used in the manufacture of hard soap, and whether it can be used alone or only when mixed in certain proportions with tallow or other fat.—Carpe Diem.

[56578.]—**Electric Bells.**—I intend fixing up a circuit of electric bells, single stroke, worked by local batteries by means of relays. Calling the different stations (of which there are seven) A. B. C. D. E. and F. A. is at distance from B. of 1 mile; C. from B. of 1¼ mile; D. from C. of ½ mile; E. from D. of 2 miles, and F. from D. (in another direction to E.) of 3½ miles. At each place I intend having a relay, but wish to know what resistance to put on bobbins of same, and size. All the relays to be connected up in parallel and line wire consisting of No. 11 galvanised telegraph wire. I wish to use the smallest number of cells possible at each place; I thought perhaps five or six would be sufficient; also give description of relays. Will No. 28 silk-covered wire do for the single-stroke bells, which are of the upright form with pivoted armature? A reply to the above would greatly help me out of my difficulty.—Electra.

[56579.]—**Pumps.**—Will some of your readers be kind enough to explain the principle upon which the American pumps work, capable of drawing water 70, 80, or 100ft. deep, and give their mode of construction?—Chappie.

# ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* Editor *of the* English Mechanic, 332, *Strand, W.C.*

## HINTS TO CORRESPONDENTS.

**1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.**

***** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.**

The following are the initials, &c., of letters to hand up to Wednesday evening, May 6th, and unacknowledged elsewhere:—

John Browning.—H. M. Thompson and Co.—E. S. Hindley.—G. Weston.—Signal Engineering Co.—Dr. Draper.—F. A. Cobbold.—H. H. Holt.—Rev. H. Dowsett.—A. Ireland.—W. Harding.—Iron Horse.—Frank Broadbent.—Vulcan.—A. Roods.—E. C.—T. J.—O. S. —Ignorant.—M. C. H.—C. E. J.—Glaston.—O. J. L. —H. Ritchie.—J. H.—J. K. P.

Young Boiler Maker. (Your query is ably answered in Mr. Nicholl's book, "The Theoretical and Practical Boiler Maker," price 7s. As a "young boiler maker," you should procure that work.)—W. G. (If you will say what it is you want to electroplate, we will point out where you will find the information; but you will, by searching the indices, discover many references to articles, &c., on the art.)—E. B. F. (Will not some of those illustrated in back volumes answer the purpose?)—Grey Hair. (Besides those mentioned, there are Mrs. Marcet's "Conversations on Natural Philosophy," Pepper's "Playbook of Science," "The Magic of Science," &c.)—Mosart. (Such a query is altogether inadmissible, as the replies must of necessity be advertisements. Look over our advertising columns, and procure the lists of the dealers in musical instruments, such as Wallis, Euston-road, and Dawkins, Charterhouse-street.)—T. J. J. (The most complete directions yet published for nickel-plating will be found on pp. 96, 117, 189, Vol. XXXIX.)—John Parton. (To obtain a berth as stoker on an ocean-going steamer, you must apply to the chief engineer on board. There is no examination: the principal requirement is what is popularly called a "cast-iron constitution.")—E. Thornton. (See indices. Indiarubber dissolved in mineral naphtha is frequently used; but Prout's glue and compositions containing guttapercha and cobbler's wax are also employed.)—B. A. (The pores must be filled with size (glue water) first of all, and when dry coat with gold size or varnish. Then when the varnish is tacky, dust on the bronze powder. Clean off with a brush when thoroughly dry.)—Domestic. (It is quite beyond our province to offer advice of the kind. The usual plan is to submit the goods to those likely to take them up.)—Young Electrician. (You do not give address. There are schools in London—the Finsbury Technical College, for instance.)—Medium. (You cannot "burnish" such articles in the technical meaning of that term; but you can polish them with crocus and a brush.)—One Anxious to Know. (We answered your queries in this column on p. 180.)—H. M. Edwards. (Your reference is to the number for March 27, not 20. The query has been answered several times in back volumes, and may be answered again. It is inserted because a reply would be information useful to many. See pp. 262, 286, 617, Vol. XXXIV., and the indices.)—Spes. (What is there to explain? You were out on the cliffs during a thunderstorm, and, in common with other people, felt a blow on the head. Many persons have had a similar experience, and some have been so unfortunate as to have been right in the path of the lightning flash.)—W. F. H. (See the indices, or one of the little handbooks of the art. The manufacturer of the plates usually supplies a formula which is known to give good results.)—R. S. T. (The first query we must leave you to answer. 2. Some specimens of corundum contain silica. 3. According to the analyses, some sapphires contain silica. 4. In return, we must now ask what you mean by "oxide of alumina," seeing that alumina is the oxide of aluminium?)—Cambo. (Yes, it is "reliable")—J. S. (Your best plan is to seek the assistance of a capitalist, as the case appears to be one of those in which the possessors of money can frighten a poor patentee.)—Camera. (You now give the size of camera, but do not state what it is you wish to know. We do not preserve the letters which reach us. Have you read one of the cheap instruction books?)—Griffith. (The query is unsuitable. You can easily ascertain the market price on inquiry.)—Little Jimmy. (If you cannot procure the back numbers you will find "The Slide Valve Practically Explained," by Joshua Rose, a useful work. It costs 5s., and can be obtained of Mr. Calvert, Great Jackson-street, Manchester.)—Stationary. (For grinding-in taps, see p. 21, No. 781. For finding horse-power, see many references in the indices. The only approximately accurate way is by the use of the indicator. The formula for calculating has been given many times, and is to be found in any pocket-book for the use of mechanics.)—Hydrathana. (Heat and pressure, sometimes comparatively sudden, sometimes gradual. 2. Where do you find the statement about the frog?)—Nemow. (We do not think there are any now; but you can easily ascertain all particulars by addressing the inquiry to the Agent-General for Cape Colony, London, S.W.)—A New Subscriber. (There are a series of articles on Spectroscope Making in Vol. XX., and several descriptions of cheap spectroscopes in back numbers—No. 774, p. 488; No. 666, p. 389; but it would be an advantage if some one who examined the apparatus exhibited by Mr. Cunynghame would explain how to make a spectroscope for 5s. Browning's "How to Use the Spectroscope," is a useful brochure. 2. Mr. Shelford Bidwell's instructions for making a phonograph appeared in Vol. XXVII. p. 157.)—British Workman. (You will find several methods of making electric contact on clocks in No. 1026. 2. It has been asserted that it cannot be done, and certainly no one but an expert could do it. A remedy is to stick a piece of silver foil over the scratch.)—Multum in Parvo. (All you can do is to sue him in the County Court for the balance.)—E. Elgar. (A little zinc ointment is the best thing you can use.)—L. H. H. (The publishers of Col. Ross's book are Messrs. Lockwood and Co., Stationers' Hall-court, E.C. Such a clock as you inquire about could, doubtless, be had of Messrs. Lund and Blockley, 42, Pall-mall, the makers to the Admiralty and the Royal Geographical Society.)—E. A. Tindall. (We will insert two more letters; but could not find space for so many illustrations with either. The subject is an interesting one, and the information you have kindly favoured us with most welcome; but, after all, it appeals to a very limited section of our readers, and we have so many matters constantly claiming their share of space.)—B. (We could only spare room for one drawing; but your kindness is as much appreciated as if we had used that you sent.)—W. H. Eaves. (In type.)

Quantum Libet. (The copy of your query about dynamo has been lost or mislaid. Will you repeat it? The blocks have been engraved.)

**Influence of the Electric Light on the Development of Plants.**—In the *Journal* of the Society of Chemical Industry is described the results of experiments carried out by P. P. Dehérain on the influence of the electric light on vegetation. Experiments in this direction had been previously made by Siemens, but not for such extended periods. The effects of the naked rays noted by Dehérain were very curious; some of the plants lost their leaves, some became spotted, weak, and unhealthy, others turned black, while in the case of some elder shrubs, leaves directly exposed to the electric rays were blackened, although the more protected leaves retained their green colour. The outlines of the upper leaves were found in many instances depicted on those underneath with the distinctness of photography. The influence on vegetatation of electric rays which had passed through transparent glass globes was not so prejudicial, although complete development was greatly interfered with. The following conclusions were arrived at by the author:—(1) The electric light contains rays which are injurious to vegetation; (2) the greater part of these rays are kept back by transparent glass; (3) the electric light contains, on the other hand, sufficient rays useful to vegetation to maintain the life of plants entirely under its influence for 2½ months; (4) this amount of useful rays is, however, insufficient to bring on young germinating plants, or to bring full-grown plants to maturity.

## CHESS.

ALL Communications for this department must be addressed to J. PIERCE, Langley House, Dorking.

PROBLEM DCCCCXXXVIII.—By ARIADNE.

| 3. R mates. | |

### NOTICES TO CORRESPONDENTS.

CORRECT solutions to 934 by G. Stingfellow, Exon (good puzzle), C. Brady, and T. L. Robins; that by E. S. Follwell is wrong.

To 935 by H. Culmer, E. Stanley Follwell (easy; five minutes), T. L. Robins, G. Stingfellow, F. B. Webb (we have repeatedly stated that if competitors desire to score full marks they must give the principal variations), Exon (key rather easy), G. W. J. and R. C. J.

To 936 by H. Culmer, Brum (very poor), A. Orr (delay unavoidable, but will not occur in future), A. A. E. Lecluse, E. S. Follwell (poor; no scope for Black), F. A. Vincent, G. Stingfellow, J. A. M. (not a first class problem), Streetgate (solution easy owing to the position of the Black K). Rev. W. Anderson (Old Romney), E. S. and R. A. Bennett.

To 937 by J. A. M. (a fair problem), Brum, E. S., J. B. Piper (very neat), and Streetgate (ditto).

H. BRISTOW.—Sorry you are unable to join Tourney, as it promises to be lively.

J. H. BLAKE.—Thanks for games and notes.

**Every Workman** connected with the Building Trades requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence, at 332, Strand, London, W.C.

"THE BUILDING NEWS" is the Principal Journal representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is One Shilling for Twenty-four Words, and Sixpence for every Eight Words after

## TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

6s. 6d. for Six Months and 11s. for Twelve Months, Post-free to any part of the United Kingdom. For the United States, 13s., or 3 dols. 26c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 4d. each to cover extra postage.

Messrs. JAMES W. QUEEN and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 26c. gold, or Thirteen Shillings per annum, post-free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 4d. each copy, to cover extra postage.

Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII., XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX. bound in cloth. 7s. each. Post free, 7s. 9d.
Vol. XL. now ready, price 7s. Post free 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post-free from the office (except index numbers, which are 3d. each, or post-free 3½d.)

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XI. and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

**Epps's Cocoa.**—Grateful and Comforting:—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—*Civil Service Gazette.*—Made simply with boiling water or milk. Sold only in packets, labelled—"JAMES EPPS and CO., Homœopathic Chemists London."—Also makers of Epps's Chocolate Essence

## CHARGES FOR ADVERTISING.

| | s. | d. |
|---|---|---|
| Thirty Words | 2 | 6 |
| Every additional eight words | 0 | 6 |

Front Page Advertisements Five Shillings for the first 40 words afterwards 3d. per line. Paragraph Advertisements One Shilling per line. No front page or paragraph advertisement inserted for less than Five Shillings. Reduced terms for series of more than insertions may be ascertained on application to the Publisher.

ADVERTISEMENTS in EXCHANGE COLUMN—for

|---|---|---|
| Twenty-four words | 0 | 3 |
| For every succeeding Eight words | 0 | 3 |

ADVERTISEMENTS in the SIXPENNY SALE COLUMN.

| | s. | d. |
|---|---|---|
| Sixteen words | 0 | 6 |
| For every succeeding Eight Words | 0 | 6 |

*** It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions; and in cases where the amount sent exceeds One Shilling, the publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O's.

The address is included as part of the advertisement, and charged for.

Advertisements must reach the office by 1 p.m. on Wednesday to insure insertion in the following Friday's number.

## NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

**Holloway's Pills and Ointment** offer to mankind the most effectual cure for Gout and Rheumatism. The Ointment should be thoroughly rubbed into the parts affected at least twice a day, after they have been fomented with warm flannels to open the pores, in order to facilitate the absorption of it.

**An Inventor** seeks a PARTNER to assist him in Manufacturing a small article of general use by all machinery users. Very little plant required.—Apply, in first instance, to J. C., 3, Gladding-road, Manor Park, E.—[ADVT.]

## OUR EXCHANGE COLUMN.

*The charge for Exchange Notices is 3d. for the first 24 words and 3d. for every succeeding 8 words.*

**Good Value Offered** (cash or instruments) for all kinds of sound or repairable scientific Appliances.—CAPLATZI, Science Depot, Chenies-street, near British Museum. Established 1862.

**Hot-Air Engine**, Buckett's Caloric, half h.-p., quite new, cost £42 10s. Will take exchange. Want tools or anything useful.—J. GRIME, Hull.

**Tricycles**, with Dunn's patent improved power appliance. 50 per cent. increase of power. Machines bought sold, or exchanged.—222A, City-road, London, E.C.

**Telescope**, 2½in. Reflector, two Astronomical Eyepieces, fine adjustment screw, on tripod stand, in oak case. What offers?—JOE BLAIN, Albert-square, Carlisle

**Medical Coil and Bichromate Battery**, in mahogany box, good condition; for Electric Scarf Pin.—JOE BLAIN, Albert-square, Carlisle.

**Electric Railway**, with Motor and Battery, not quite in working order; can be made right by any amateur electrician. What offers?—JOE BLAIN, Albert-square, Carlisle.

**Lathe Heads**, 4½ to 6in. centres, T and slide rests, wanted in exchange for corresponding value.—LINSCOTT, Ramsgate.

**Telescope**, 2in. achromatic object-glass, good definition, high tripod stand; for Lathe Appliances or other offers.—LINCOTT, Ramsgate.

"Sun Dial" Gas **Cooking Stove**, nearly new, two feet high, thirteen inches wide, eleven inches deep, complete, cost £2 8s. Will exchange for assortment of joiner's tools of approximate value.—Address, P. T., 227, Millbrook-road, Freemantle, Southampton.

For exchange, a Dr. Carter Moffatt's **Ammoniaphone**, quite new, owner has no use for it, been very little used. Exchange for small Shocking Coil or what offers.—REYNOLDS, Hepworth, Huddersfield.

"**English Mechanic**," from beginning, 40 vols., handsomely bound. What offers in cash? or exchange Photographic Apparatus, Tricycle, or anything useful.—Address, X.Y.Z., 8, Albany-road, Mile-end.

**Letter Copying Press**, foolscap size, quite new, never been used, cost £2. Will exchange for Printing Press or offers.—JAMES R. W. STIBBS, Commercial Wharf, Plymouth.

Wanted, pair 3in. centre **Lathe Heads and Rest** or Electro-Motor, any other Electrical Apparatus. Exchange 5-keyed Piccolo, with silver lip plat on, cost 32s. Offer.—B. SCHOFIELD, Diggle, Saddleworth.

Splendid **Electro-Motor**, Chester's form, but larger adjustable brush holder; for Bassinette or useful offers.—J. SMETHURST, 4, Oak-street, Radcliffe.

Wanted, set **Dynamo Castings**, about 150 c.-p., in exchange for Pint Bunsen Cells.—E. THORNTON, Hindpool-road, Barrow-in-Furness.

Offers wanted for a 6in. centre Woodturning **Lathe** and 4½ Leg Vice.—No. 3, Stanhope-street, off Winwich-road, Warrington.

Mahogany **Steering Wheel**, with drum, standards, and mahogany case, suitable for boat about 30ft.

**Propeller**, 26in., 3-bladed.

**Lathe Flywheel**, 28in. dia., and Crank.

Vertical copper **Boiler**, 24in. high, 10in. dia., 7 tubes, and all fittings, with firebox, &c

Horizontal **Engine**, brass, 2in. bore, 3½in. stroke, on brass bed-plate, in working order.

Offers in exchange or cash. Wanted, **Donkey Pump**, steam fittings.—A. G., 23, Sussex-street, Winchester

A beautiful **Russian Goatskin Rug**, cream colour, 6ft. long by 3ft. Exchange for Hand Sewing Machine or anything useful.—H. NELDER, Bridge-street, Abertillery, Newport, Mon.

**Dynamo**, superior finish, 10½in. Siemens armature, in exchange for good 6in. Slide-rest, or cash £5 10s.—J. BAMBER, 12, Bessborough street, London, S.W.

Wanted, a **Copying Apparatus**, for which good exchange will be given. Gelatine forms will not do.—T. H. M., Errigle, Cootehill, Ireland.

Horizontal **Engine**, link motion, locomotive boiler, 8 tubes, steam and water gauges, &c.; for 6in. Slide-rest, or offers.—SARGENT, 25, Holywell-street, Strand, London.

Wanted, an **Air Gun**, in exchange for a HORIZONTAL ENGINE and BOILER, in very good condition, cost 25s.—H. WILSON, Rock House, Clapham Common

Half-plate Sliding Body walnut **Camera**, dark slide lost, excellent condition. What offers of exchange?—STEAD, Lees, Oldham.

Going abroad.—**Induction Coil**, remainder Chemical Apparatus, Books, &c. Nominal exchange.—R. PORTER, 30, Aden-grove, Stoke Newington.

Newton's Patent Refulgent **3-wick Lamp**, new this season. Will exchange above for the "Safety Oxy-hydrogen Jet," or offers. Approval.—E. HOWGATE, jun., Water Hall, Mirfield, Yorkshire.

**Locomotive Castings**, Lee's, £2 15s. set, 18in. long; partly finished, cylinders bored. What offers in exchange Small Harmonium wanted.—MILLER, 3A, Park road, Battersea.

**Bicycle** wanted, 50in. to 54in. Will exchange GALVANIC BATTERY, by Halse, cost £10.—C. F., 19, Merrow-street, Walworth-road, S.E.

"**Popular Educator**," Vols. III. and IV., separately bound and in good condition. Exchange or offers.—POOLE, St. James's-green, Thirsk, Yorkshire.

Volumes I. to XIV. "**Mechanic's Magazine**," bound, good as new; 10 Vols. "Family Friend," bound; and other books, in exchange for Lathe and Tools, or offers.—W. S., 78, Viaduct-street, London, E.

52in. **Bicycle**, bent handles, lamp, bell; good as new Would exchange for good centre-second Chronograph Stop Watch and Chain.—HOWARD, 177, Guide-lane, Hooley-hill, Manchester.

Wanted, second-hand ¾in. spark **Induction Coil**, with commutator, in exchange for 6in. Bullseye and safety Lime Light Jet.—M., 5, Hanover Buildings, Southampton.

For exchange, about 100 yards of No. 16 copper thick Guttapercha WIRE. Exchange Silver Albert; also 2 Electrical and Pneumatic Indicators, 10 holes each, good condition. What offers?—W. MITCHELL, Engineer, Leicester.

Wanted, lady's hall-marked **Silver Lever Watch**, no rubbish, hunter preferred, for good exchange.—Particulars to T. A. C., Fairfield House, Warrington.

**Foot Lathe**, new, 3in. centres, 2ft. 6in. gap bed, treadle, tool shelf, back gear, compound slide rest. Exchange for Breechloader, equal value, choke preferred.—A. HALLS, Howard-street, Yarmouth.

Wide-angle **Lens**, first-class maker, Vogel, Philadelphia, U.S. Want ½-plate Portrait Lens (offers photographic).—H. REYNOLDS 77, West-street, Bristol.

Ten-guinea **Diamond Ring**, new, flawless, in exchange for 2ft. Locomotive in damaged condition.—Send particulars to W. HAUGHTON, 138, Park-road, Liverpool.

"**Flute Music**," in exchange for C. Nicholson's Pot-pourri and Weidner's Portuguese Air, flute and piano. One or both.—Particulars, J. DICKSON, Atlantic Avenue, Belfast.

54in. **Bicycle**, roller bearings, lamp, &c. Exchange for "Facile" or smaller bicycle, or sell cheap; also some locomotive photos.—W. ALGAR, Stonard-road, Winchmore-hill.

Double **Dark Slides** (2), quarter-plate, nearly new. Exchange turning tools, or offers.—J. T. SKINNER, Turner, Chase-road, Southgate, London, N.

"**English Mechanic**," Vols. I. to IV., bound; XXI. to XXVI., bound; XXVII. to XL., unbound, clean and complete. "Horological Journal" from commencement, 27 Vols. complete, to August, 1885, 19 Vols. bound. Tricycle or offers.—H. W. JOB, High-street, Harrow, Middlesex.

Wanted, good **Lever Watch**. Exchange WOODTURNER'S FOOT LATHE, 30s., Avery's Steelyards, weighs 14lb. up to 15cwt., cost £5.—W. SMITH, Bilston-road, Wolverhampton.

## THE SIXPENNY SALE COLUMN.

*Advertisements are inserted in this column at the rate of 6d. for the first 16 words, and 6d. for every succeeding 8 words.*

**Plating.**—Every description of Gilding, Silver Plating, Oxidising, and Bronzing, executed with very best finish. Speciality in nickel-plating. Special quotations on application. Send one stamp for price list. Small jobs attended to per return post.—MORRIS COHEN, 132, Kirkgate, Leeds.

**Fretwork.**—Illustrated Catalogue of every requisite and 400 miniature designs, 4 stamps.—HARGER BROS., Settle, Yorks.

**Trouser Lengths**, 5s. each. Cheap Cloth for Ladies' Dresses, Mantles, Boys' Suits.—HEWITT, 27, Winfield Mount, Leeds. Patterns free.

**Electric Depot**, 10, Deansgate, Manchester.—Electric Breast Pins, 25s. Electric Bells, 4s. Induction Coils, 8s.—MILLAR, Proprietor.

Shunt wound **Dynamo** and Serrin Arc Lamp, cost over £40. Will take £25 or good exchange.—JOHN GRIME, Hull.

Fletcher's **Foot Blower**, cost 35s., quite new; also large Blow Pipe and Hearth. Will take £2 10s., or offers.—J. GRIME, Hull.

**Billiards.**—Great success of Thorpe's Patent Automatic Cue Tips. Cannot fly off. Cues retipped instantly.

**Billiards.**—Excellent testimonials from Roberts, jun. champion, and other professionals. £5 per week easily earned.

**Billiards.**—District Agents wanted. Send 9 stamps for particulars and sample cue end fitted with patent.

**Billiards.**—Five Shillings for sample one, also fitted, and 3 extra tips. Thousands already in use.

**Billiards.**—Apply to sole representative for United Kingdom.—A. W. MORGAN, Lancaster Avenue, Fennel-street, Manchester.

Hard **Vulcanised Fibre** for Magnet Heads.—MOSSES AND MITCHELL, 68a, Chiswell-street, London, E.C.

Hard **Vulcanised Fibre** for all kinds of insulation.—MOSSES AND MITCHELL, 68a, Chiswell-street, London, E.C.

**International Inventions Exhibition**, East Avenue, Group 21, Stand 1683.—MOSSES AND MITCHELL, 68a, Chiswell-street, London, E.C.

Tudsbury and Sons' "High Tension" **Wimshurst** MACHINES, with Compound Ebonite Plates. List, one stamp.—Edwinstowe, Newark.

**Castings.**—Bench Drilling Machine Castings, 3s. 6d. Small Brass Horizontal Engine Castings, 2s. 6d. New Price-list and designs of perfect Castings post free.—I. TOMLIN, Engineer, 28, Highfield-terrace, Barnsley, Yorkshire.

**Castings.**—Half horse-power (Engine), Launch. Horizontal or Vertical, ports in cylinder. Complete sets Forgings and Castings, 12s. 6d. One horse-power, 25s.—TOMLIN, Highfield terrace, Barnsley.

**French Polishing**, Staining, Painting, and Varnishing. 122 receipts or trade secrets, with full instructions and details, free 1s.—I. Tomlin, 26, Highfield-terrace, Barnsley, Yorkshire.

**Cat Gut.**—Gut Hooks and Eyes for lathes and machinery.—James Bellaers. Regent-street, Leicester.

**Bellaers' Gas Stoves.** 1s. 3d., 2s. 3d., 3s. 3d., for boiling. Breakfast stoves, 5s., 11s., 14s. 6d. Send for lists.

**Showcases** for Exhibitions, Models, Scientific Instruments. Exhibition Stands supplied and fitted.—Write, Fry and Blatt, 90, Borough-road, London.

24 **Microscopic Slides**, in box, very cheap. List sent for stamp.—Well, Dalmain-road, Forest Hill.

**Mica**, otherwise Talc.—Richard Baker & Co., 9, Mincing-lane, London.

**Violin** for sale, magnificent solo instrument, suitable for lady or gentleman, labelled "Antonius Stradvarus, Cremona. 1690," with good case and mounted bow, only 25s. Sent on approval with pleasure.—Mrs. Jones, 50, Myddelton-street, Clerkenwell.

**To Capitalists.**—An Inventor seeks a Partner to assist him in manufacturing a small article of general use by all machinery users. Very little plant required.—Apply in first instance to J. C., 3, Gladding-road, Manor Park, E.

**Patents, Designs, and Trade Marks.**—For particulars of lowest charges, apply, G. L., Technical Bureau, 46, Queen Victoria-street, E.C.

**Tricycle Wheels**, Bicycle Wheels, and Fittings. Wonderfully cheap. Also for safety Bicycles.—W. Gwinnett and Co., Wolverhampton.

**Edward W. Drury**, Hull, Glass Bottle and Cork Manufacturer, Importer of Chemicals, Caramel, Glucoses, Tinned Wire.

**Lathes**, Lathes. Cheapest and best. List, 2 stamps. Nothing equal at price.—Robinson, Somerset-road, Sheffield.

100 **Foreign Stamps**, including Brunswick, Ceylon, Tasmania, Egypt, Greece, Luxemburg, free 7d.—Hely, Foley-street, London.

Patent Spiral Grip **Letter Racks.** "An invaluable invention." Parcels post, 1s. 3d.—Iles, Highgate-street, Birmingham.

Pumphrey's **Pocket Tripod**, for cyclists, professional and amateur photographers. Perfectly rigid. May be had on approval. Illustrations and testimonials free.—Pumphrey, Stanhope-street, Birmingham.

The **Camera and Lantern**, with three instantaneous photographs; gives full instructions in their production; 6d. post

**Camera and Lantern Apparatus**, dispenses with multiplicity of slides, 36 plates carried, changed anywhere.—Pumphrey, Birmingham.

Pumphrey's **Hydrostatic Shutter** gives instantaneous or timed exposures; 10s. Illustrations post free.—Pumphrey, Stanhope-street, Birmingham.

**Motor Castings**, materials for Electric Bells, Batteries, Galvanometers, Intensity Coils, Microphones.—King, Mendham, and Co., Bristol.

**Insulated Wire Table**, showing size, weight, resistance per foot, feet per ohm, &c., price 3d.—King, Mendham, and Co., Bristol.

**Standard Ohm**, in box, copper poles, guaranteed correct to ten thousandth of ohm, 21s.—King, Mendham, and Co., Bristol.

**Wimshurst Influence Machine.**—Sole Manufacturers of Improved Pattern. Numerous testimonials as to thorough efficiency.—King, Mendham, and Co., Bristol.

**Galvanometer Cards**, improved for tangent and ordinary combined, 2½in., 8d.; 4in., 10d.; 6in., 1s.; post free.—As above.

Write for **King, Mendham, and Co.'s** large new and reduced Price List, post free 4 stamps.

Col. Ross's Patent **Filter Pipe**, price 1s. 6d., post free 1s. 8d.—G. Deal, 7, Holborn Viaduct, London, E.C.

The **Pipe of all Pipes.** Price 1s. 6d., post free, 1s. 8d.—See above.

Patronised by the **Prince of Wales.** Price 1s. 6d., post free 1s. 8d., at above address.

**Recommended** by the English Mechanic. Price 1s. 6d., post free 1s. 8d.—G. Deal, 7, Holborn Viaduct, London, E.C.

A **Sure Cure** for Dyspepsia and Heartburn. Col. Ross's Patent Filter Pipe.—See above.

**Selling by Thousands.**—Try one if you have not seen it. Price 1s. 6d., post free 1s. 8d.—G. Deal, 7, Holborn Viaduct, E.C.

Smoked all the World over.—**Col. Ross's Patent** Filter Pipe. Price 1s. 6d., post free 1s. 8d.—See above.

**Beware of Imitations**, useless and fraudulent. We sell only Col. Ross's Patent. Price 1s. 6d., post free, 1s. 8d.—G. Deal, 7, Holborn Viaduct, London, E.C.

**Col. Ross's Patent Filter Pipe.**—Look out for it at the "Inventories" Exhibition; meanwhile buy one of us.—G. Deal, 7, Holborn Viaduct, London, E.C.

**The Kinetic Engineering Company**, 36 and 37, Brooke-street, Holborn, London. Circulars and list post free.

**Dynamo Wire**, 1s. 2d. per lb. Line Wire, 29s. 6d. per mile. Pushes, 4s. per dozen.—Kinetic Company.

**Leclanche Cells**, best No. 1, 16s.; No. 2, 19s.; No. 3, 22s. 6d. per dozen.—Kinetic Company.

**Electric Bells.**—Best quality, workmanship, appearance and value in market, 40s. per dozen.—Kinetic Engineering Company.

**Maiche Patent Battery.**—Best yet produced. Circulars and Scientific Reports post free.—Kinetic Engineering Company.

**Electrical Supplies.** Wholesale only.—Kinetic Engineering Company, 36 and 37, Brooke-street, Holborn, London, E.C.

**Devonshire Cream**, delicious, by improved centrifugal process. Parcels Post, 1b., 1s. 6d.—G. Bull, Manor Farm, Martock, Somerset.

**Planing**, not exceeding 10in. by 10in. by 8in.—B. W. Cleoe, 18, Belinda-street, Hunslet, Leeds.

For **Model Work** (wheel-cutting in brass only); also Boring, Turning, and Screw-Cutting.—Cleoe, as above.

Grant Bros.' parts of **Electrical Apparatus** of every description for amateurs; wholesale prices; full instructions free.

**Electric Bells**, Batteries, Pushes, Wire, wholesale prices; list free.—Grant Bros. and Co., 20, High Holborn.

**Engine and Boiler** combined, 6in. bore, 12in. stroke, by Green; very cheap.—Rigby Smith, Fazackerley, Chorley.

Universal **Cutter Frame**, slide 3in., £2. Castings 4s. 6d.—Particulars, apply, G. Allsop, Derby-road, Belper.

**C. Pilkington**, 32, Sackville-street, Piccadilly, W., Magic Lantern Artist and Photographic Colourist.

Magic Lantern **Photograph Colouring**, finely and artistically done, 12s. per dozen. Special terms to the trade on application.—C. Pilkington, 32, Sackville-street, W.

**Desmometer**, giving at sight weights of rivets and bolts of any size and length. Useful formulæ, 1s.—W. Stephen, 76, DeGrey-street, Newcastle-on-Tyne.

**Oxygen Gas**, compressed in cylinders, handiest and safest for limelight.—Clarkson, Compressed Gas Chemist, Bartlett's-buildings, E.C.

**Oxygen Gas**, compressed into iron bottles, liquid nitrous oxide and carbonic acid.—Clarkson, Compressed Gas Chemist.

**Oxygen Gas**, compressed into iron bottles; prices on application.—Clarkson, 28, Bartlett's-buildings, Holborn, E.C.

Astronomical **Telescopes** of all kinds and Apparatus or Fittings made by A. Clarkson, 28, Bartlett's-buildings.

**Eyepieces.**—Huyghenian of any power to fit any telescope, 15s each. Sun Diagonals, £1. Star Diagonals, 30s.

Astronomical **Telescopes**, second-hand, by best makers.—Clarkson, 28, Bartlett's-buildings, Holborn, E.C.

Model **Steam Engines** made or repaired. Separate parts fitted up, boilers made to order.—Lucas and Davies, 21, Charles-street, Hatton-garden, London.

**Tricycle House**, full size, portable, hold two bicycles, £5 10s., carriage paid.—X., 7, Clarence-street, Liverpool.

**Square or Hexagon Articles.**—Full directions how to turn these in any ordinary lathe, including catalogue of lathes and parts of lathes. Any amateur can fit it up. Send eight stamps.—Britannia Co., Colchester. Inventions Exhibition, 91 Stand, Main Avenue.

**Square Hole.**—How to cut square holes by hand tool. Anyone can do it. Eight stamps, including catalogue.—Amateur Department, Britannia Works, Colchester.

Second-hand **Lathes** and various items. Give details of what you require. Stamped envelope for list of second-hand lathes, &c.—Britannia Co.

**Note the Address.**—Britannia Company's London Showrooms, 99, Fenchurch-street. All correspondence to Colchester.

Several nearly new **Lathes**, similar to those on view at 99, Fenchurch-street. Also Rests. Send details of what you require.—Britannia Works, Colchester.

**Engineer's Tool Department.**—Lathes, Shapers, Planers.—Britannia Co., Colchester. Makers to the British Government.

**Britannia Co.** exchange any articles unless made to order. Tools and Machinery to design.

**Boiled Oil** quick dryer, something new, full working instructions, 6s.—J. Murray, 6, Hamlet-street, Bootle, Liverpool.

Odd **Spiral Spring** made to order. Mattress Spring 9d. per dozen.—James Parish, 52, Bard-street Park, Sheffield.

**Elastic Stockings**, Knee Caps, &c., best remedy for Varicose Veins, Swellings, Weakness, &c., from 3s. 6d. Directions for self measure free.—Smith and Son, 6, Westborough, Scarborough.

**Microscopes.**—Apparatus, Alterations, Repairs, and Objectives. R. G. Mason (from J. Swift), Microscope Maker to the trade. All kinds of scientific instruments repaired. Stamp for list.—24, Park-road, Clapham, London, S.W.

6in. Kennan **Lathe and Appliances** for high-class ornamental turning, for sale. Property of an amateur lately deceased.—Particulars, Rev. Joseph Rawlins, Bawnboy, Ireland.

Seven years' "**English Mechanic**," all complete, ready for binding. First P.O.O. for eight shillings has the lot.—J. S. Bonnard, 18, Holgate-road, York.

**Copying Ink Pencil**, new patent indelible, Cam action; best ever introduced. Warranted to wear well. Post free 7 stamps.—Purkiss, 37, Huntingdon-street, Kingsland.

Profitable pursuits in Leisure Hours!—**Blowpipe** and Lamp combined, handy little instrument for blowing joints; every requisite; book of plain instructions; in box, free 2s. 6d.

**Soldering Apparatus.**—Soldering Iron, Heating Lamp, solder, every requisite, book of instructions, packed in box, 3s. 9d. free.—J. Irving, 14, Queen-street, Gravesend.

"**Hints on Egg Collecting**," illustrated Pamphlet, 9d. Drills and Blowpipe, 1s., free.—J. Davis, Naturalist, Dartford.

3¼in. Wray **Telescope**, excellent definition, good as new, objects and full particulars.—T. Clapham, Austwick Hall, Lancaster.

**Boiler** (egg-end), 8ft. by 33in., and part fittings.—Mills Bros., Belmore-street, Wandsworth-road, S.W.

**Smith's Bellows**, oblong, 32in., good condition, 30s.—Mills Bros., Belmore-street, Wandsworth-road, S.W.

**Organ Pedals**, mahogany; must be sold.—H. Reid, Addington Villa, Wendover, Bucks.

**Thought-Reading.**—A full explanation for 7d.—J. B. Parr, Ainsworth, Bolton, Lancashire.

**Diagrams**, large crayon, plain or coloured, for lectures in natural history or microscopy.—Parr, Ainsworth, Bolton.

Ivory handle **Pocket Knife**, 3 best steel blades, 2s. 9d.; sold at 3s. 6d. and 4s. Cash returned if not approved.—Marsh, Broughton-road, Owlerton, Sheffield.

A Stanley **Histological Microscope**, with spot lens, but without objectives, polished mahogany box, equal to new, price £2 5s.—M. Q. C., 73, Clarence road, Clapton, E.

**Electric Bell**, Battery, Push, and 30 yards of Wire, carriage free, 9s.—A. Shafto, Urmston, Manchester.

**Electric Bell**, 4s. Leclanché Battery, 2s. Bichromate, 3s. Coil, 6s. Wire ½d. per yard.—As above.

All **Parts and Fittings** of the above cheap, with instructions for amateurs to construct.—As above.

**Perambulators.**—Several good second-hand, cheap, at J. Johnson's, 87, New Oxford-street, London, W.C.

**Mica or Talc cut** for all purposes by C. Johnson, 87, New Oxford-street, London, W.C.

**Piles cured at once** by using Dr. Farquharson's Remedy. Free by post for 2s.—2, Standish-street, Burnley.

**Standard Ohms.**—S. Bottone has a few of these on hand, price 2s. 6d.—Stanley-road, Carshalton.

**Wheatstone's Bridges.**—S. Bottone can also supply a few of these, price 6s., post free.

**Living Rotifers**, &c., for the microscope. A tubeful, post free, 6d.—Arthur Bottone, Stanley-road, Carshalton.

Quarter-plate **Photographic Set**, complete in box by Stanley, as good as new, cost 50s.; will sell for 35s. as I have got half plate set.—Address, J. Hargreaves, 15, Ivanhoe-road, Denmark Park, London, S.E.

**Incandescent Lamp**, 8d. post free. Only a few left.—New and Co., 24, Dean-street, Soho.

**Incandescent Lamp** in Gilt Scarf Pin, 20 stamps.—New and Co., 24, Dean-street, Soho.

**Incandescent Lamp.** Battery, Wire, Chemicals, Instructions, &c., in box, 2s. 6d. free.—New, 24, Dean-street, Soho.

**Why Pay many Times their Cost?**—Easily made. See below.—Stanley, 119, Manchester-road, Poplar, E.

Stephens' **Blue Black Ink**, Eno's Fruit Salt, Davis's Pain-Killer, Browne's Bronchial Troches.—See Stanley, above.

**One Recipe**, 7 stamps; two, 12; three, 16; four, 19. Returned if dissatisfied.—Stanley, above.

Genuine Commercial **Citrate Magnesia**, as prepared by largest firm in trade, 13 stamps. Returnable.—Stanley above.

A New Varnish.—A **Spirit Copal**, as clear as filtered water. Never produced before. Dries in five minutes. Smooth and brilliant. Sample Bottle 7 stamps, post paid.—S., 5, Coventry-street, London, W.

**Patterns** of 3in. Screw-cutting Lathe. No reasonable offer refused.—Bullocoh, 6, Mead's-row, Lambeth.

**Coca Leaves.**—The Bolivian Consul-General has sent a splendid testimonial this week in favour of their stimulating properties.

**Coca or Cuca Leaves.**—Many M.P.'s and Clergymen take them constantly. To Cyclists they are a positive necessity.

Persons afflicted with **Indigestion** should chew Coca instead of eating a hearty dinner, and they would soon be cured.

**Coca Leaves.**—Sample packet, with medical and scientific opinions, 13 stamps.—Marks and Co., 17, Newcastle-street, Farringdon-street, E.C.

**New Time.**—Alter your Clocks and Watches. Twelve Sets of Figures, with instructions, 6d.—Wheeler, Preston.

**Water Motors**, for sewing machines, organettes, window advertisements, 32s., 42s. List one stamp.—Wheeler.

**Fan Castings.**—Improved Registered Designs; sets 4in., 3s.; 6in., 4s.; [illegible]in., 6s. Drawings, 6d.—Wheeler, Engineer.

**Water Motors.**—Complete one horse-power, £9. Half, £6. Quarter, £4. Eighth, £3.—Thomas Wheeler, Preston.

Steel **Name Stamps**, 3d. per letter. Figures (set), 2s. 4d. Letters, 6s. 4d., per post.—E. F. Baldwin, Robinswood-hill, Gloucester.

**Dynamos**, Jones's Patent, 2,122, working at 12, Old London, in International Inventions Exhibition. Motor Castings, 3s. a set.—H. Jones.

**Formulas Worked Out** for winding Dynamos from 10 c.-p. to 500 c.-p., 8 stamps each.—H. Jones.

**Dynamo Castings**, Jones's patent H: 8 c.-p., 5s.; 16, 6s. 6d.; 20, 6s. 6d.; 30, 7s.; 70, 16s. a set.—H. Jones.

**Dynamos**, finished: 8 c.-p., 30s.; 16, 36s.; 20, 40s.; 30, 50s.; 70, 100s. each.—H. Jones.

**Dynamo Armatures** of above wired after fitted up 1s. each, own make, warranted.—H. Jones.

**Dynamos** for house lighting.—Jones's Patent Laminated Poles and Armatures, 5, 6, and 7 lights, £6, £7, and £8 each.—H. Jones.

**Dynamo Machines Repaired.** Motors, with wire, 6s. 6d.—H. Jones, 48, High-street, Lambeth, S.E.

Model **Engine Castings.**—Best and cheapest. See list (stamp) and compare.—Wood, Dalley-street, Broughton, Manchester.

**Dynamos**, with lamps, new. Fine Hand Machine, by Brequet, cost £40; first offer above £15 taken. Inspection invited by appointment. Castings rough and finished. Repairs.—Letters, Warne, 39, St. John's-street-road, E.C.

Hardy **British Ferns.**—Asplenium Marinum, Viride, Ceterach Crenatum, Lastrea Æmula, Rigida, Celina, Oreopteris, Dilatata, Polypodium Semilacerum, Calcareum, Oak, Beech, Athyrium, Scolopendrium, 15, 1s. 6d.; 20 large Rockery Roots, 2s.; 50, 4s. 6d.; 100, 8s. Botanically named, carriage paid.—John Burns, Fellside, Kendal.

A few Gramme **Dynamos** for sale, cheap.—Walker and Olliver, 195, Severn-road, Cardiff.

**Electro-Motors** from 25s. No dead point. Battery equal Bunsen's. No fumes.—Walker and Olliver.

Leclanché **Cells**, Manganese, Sal-ammoniac, Bichromate Bells, Wire, Pushes. Wholesale and retail.—Walker and Olliver.

**Dynamos** repaired or rewound. Advice given. Competent men sent to all parts.—Walker and Olliver.

Send for **List** of Switches, Indicators, Telegraph Instruments, Parts, &c., for sale, cheap.—Walker and Olliver.

**Lenses**, Instructions, &c., complete for constructing powerful telescope, 36in. long; 1s. 3d., free.—Theobald, South-street, Greenwich.

French Cuirassier's **Sword and Sheath**, Waterloo pattern, thorough order, 10s. 6d., bargain.—Theobald, South-street, Greenwich.

Small Gold Lever **Watch**, 14c., excellent timekeeper, compensation balance, 50s. Great bargain.—Theobald, South-street, Greenwich.

**Telescopes**, Opera and Field Glasses, Model Engines, &c., at absolutely wholesale prices.

**Illustrated Catalogues**, two stamps.—A. Francois, specialist, Ryland-road, Birmingham.

**Repousse Work.**—Every requisite, with instructions, supplied by A. Francois. Particulars on application.

"**Bazley's Index to Geometric Chuck**," new, 32s. Holtzapffel's, price 42s.—Lay, 16, Bear-street, Leicester-square.

**Dynamo**, new, laminated armature, lights 7 tens; price 70s.—J., South Cottage, Thurlow Park-road, Dulwich.

Finest **Crystal Oil** for cooking stoves, 6½d. per gallon. Virgin Cork, 14s. 6d. and 16s. per cwt. Pure Methylated Spirit from 2s. 10d. gallon. Gasoline, Benzoline, Varnishes, Polishes, Stains, &c., &c.—H. Jones and Co., Viaduct-street, London, E.

**Induction Coil**, ⅜in. spark, with condenser, 30s. free.—A. Parks, 43, Coten-end, Warwick.

Horizontal **Engine and Boiler**, 1½in. bore, in working order, 35s.—H. W., 21, Bellevue-road, Southampton.

**Launch Engines** for sale, 3in., 4in., 4½in., 5in., 6in., 9in. cylinders.—John Middleton, 16, Hope-street, Glasgow.

**Lathes**, 5in. centres, back-geared, complete with chuck, chuck, &c., £7 10s.—John Middleton, 16, Hope-street, Glasgow.

"**English Mechanic**," Vols. XXII. to XL., inclusive, unbound, 45s.—W. M., 64, St. Stephen-street, Salford.

The English Mechanic
AND WORLD OF SCIENCE AND ART.
*FRIDAY, MAY* 15, 1885.

## TOOL EDGES, CUTTER BARS, AND CUTTERS.

THE query of a correspondent in a recent number has stimulated me to take pen in hand once more, and to resume a subject which can hardly fail to interest a large number of our readers, of whom many are new subscribers, who have not had the opportunity of reading previous articles in which this matter was more or less fully treated. For many years, too, I have had in my hands private notes and letters of "D. H. G.," in which he explained the whole system, and his reasons for adopting the bar known by his name. It was his intention to publish further notes in a separate pamphlet; but time went by, and his business engagements being of a pressing nature, he was never able to carry out his plan, and sickness—the result, I believe, of overwork—has now compelled him to lay aside the pen, as well as those lathe tools which he wielded so skilfully, and handled, I may say, so lovingly. I feel, therefore, justified in attempting this work myself, and in so doing I shall follow the plan which he would have himself adopted: of making each individual point clear before passing on to the next. In no other way is it possible to elucidate the system upon which the cutter bar and its tools depend for their efficiency. I am well aware, nevertheless, that some other correspondents are better qualified to do this work than I am, but I write for learners, and not for masters; nor would I write at all if "D. H. G." was in health or "J. K. P." at leisure and in the mood. No detail, perhaps, of lathe-work causes an amateur more worry and disappointment than metal-turning. He sees, probably in a lathe in some large workshop, a bar of metal in process of manufacture, and observes the shavings curling off its surface under the action of the tool, as if the material were almost as easy to pare as an apple. Trying to imitate the process at home, he becomes practically acquainted with the fact that knowledge and experience are needed to a degree which he can scarcely comprehend, and that metal-turning no more comes by nature than reading and writing. But what is still more aggravating is the fact that with a well-ground hand-tool—a graver, for instance—the tyro often finds that he can cut a clean shaving with far greater ease than with the slide-rest tool, while he naturally feels ambitious to excel with the latter. Let anyone take a graver and hold the lozenge-shaped face flat against the end of a bar mounted in the lathe, letting it lie, of course, across the tee of a rest put as closely as possible to the work. Then let him gently bring the upper edge into cut by inclining the face slightly towards the work. The cutting action will be so easy that no exertion is necessary to hold the tool steadily—the resistance is so apparently slight that he may hold the tool with thumb and forefinger, even, for a light cut. Using, however, both hands, no difficulty is experienced in taking as deep a cut as is generally needed. Why is it that the substitution of a slide-rest tool for the graver does not bring about a far superior result, as it ought theoretically to do? In the first place, the graver is correctly formed; the cutting angles are those best suited to separate the shaving, and, in the next place, the position of the tool is accurately, because tentatively, adjusted. If it is seen to fail in its work, an almost imperceptible movement of the hand corrects the error of position, and sets matters right.

With the fixed tool, even if it is correctly ground, no such minute correction is possible as tool-holders are now made; but the tool must be packed-up, or re-ground, or lowered, as may seem necessary, and again tried—often with the result that it has again to be ground and readjusted. It is not very easy to contrive a holder that will place a graver in the position mentioned above, nor is it really necessary, because we can give to a slide-rest tool any desired cutting angle, and also place its edge quite as favourably, while we can retain it rigidly in exact position.

If we consider attentively the cutting-action of the graver, placed as stated, we shall observe, first of all, that the lozenge or face lies almost flat against the end of the bar to be cut, the slightest possible leaning

of that face to the left bringing its edge into action. This should be practically tested by the reader. The small angle made by the face of the tool with the work is known as the clearance angle, and the smaller it is the easier will the cutting-action be. We have, therefore, the first secret—viz., a small clearance angle between the work and the face of the tool which is next to it. Then, secondly, if the graver is ground as usual to an angle of 45° with its length—i.e., more correctly, if the face makes 45° with the axis of the bar, each cutting-edge will be 60°. Now there are many who ridicule this measurement of cutting angles, notably American writers; but it stands to reason that on any given material—e.gr., wrought iron—there must be a certain keenness of edge, which will give the best results, lasting longer and cutting better than any other. It may vary within certain limits, because a bar of wrought iron is not always precisely alike in its structure; but the best average for this metal will be 60°, and a graver will cut it extremely well. We may, therefore, take it as about the angle to which a tool for wrought iron should be ground.

Thirdly, the position of cutting edge.—This, for reasons that will presently be stated, should be always at the height of the lathe centres. With a hand graver it is of no special importance, because the cut is not continuous, and, after a shaving has been removed, we readjust the tool for a second cut; but for a fixed tool, the axial horizontal plane is the only one that will answer. If the cutting edge is above the line of centres, the face of the tool will rub unless the clearance angle is unduly large; and if it is below the centres, the work will have a tendency to ride up on the tool and break the edge. No really good work can be done unless the tool is accurately set to cut on the line of centres, especially if the work be of small size. In the latter case, which is that most frequently met with by the amateur, I have found that a rather greater clearance angle is better than the typical one of 3°. There is no such hard and fast line that a departure from this small angle can be considered wrong; and if it is always retained, the difficulty of accurately adjusting the height of tool will often be considerably increased. The accepted limit has been stated to be 3° and 6°. There are, however, other matters besides clearance and rubbing which have to be considered, which are dependent on the size of this angle. These will be understood presently.

Let us take one detail at a time. Fig. 1, A, represents a cylinder in section turning on its centre; B C is a tool by which it is to be turned. Its edge is a bad one, but let it stand for the present. Observe here that this edge is of 87°, because we have ground away the 3° of the right angle to get the clearance angle, by which the face of the tool is prevented from rubbing. Notice also that the edge is placed on the line of centres D D. Such a tool, thus placed, would cut brass, but is not sufficiently keen for iron. In Fig. 2 the tool is supposed to have advanced considerably. The cylinder upon which it is acting has become much smaller; but it will be seen that all the conditions are the same, the tool occupying the same position and retaining the same clearance. In Fig. 3 the same tool is applied above the line of centres D D; but now the end of it rubs against the work, and the higher it is placed the greater will this effect be. Now let the edge lie below the line D D, as in Fig. 4; it will not rub, but by-and-by the edge will be out of cut, and the smaller cylinder cannot be further reduced. There is another drawback to these faulty positions, but the easiest method of grasping details is to take one step at a time; and here I am only considering the position of the edge, and its effect upon the clearance angle. Of course the defects are here exaggerated; by placing the tool considerably above or below the line of centres; but the effect will be felt in any case, and we are trying to understand why one position or one angle is better than another. If we only had this clearance to consider, we might easily place the tool above centres, and then grind away to 6° to make it clear; but there would be no advantage gained by so doing, and it would materially affect the tool in another way.

The next consideration will be the cutting edge, and for the present I will speak of it as an "end on" tool—*i.e.*, it is to stand square to the work, so that it can be traversed in either direction with equal effect. Fig. 5 represents the tool in profile, which has been already used in illustration of the clearance angle; and, as I stated, it is a very blunt and, for iron, a very bad tool. To give it a greater clearance angle will not sharpen it: it will only weaken the edge, leaving it a mere scraping tool as before, because its upper face is at right angles to the work. It is this upper face, therefore, that we must attack, and we can file out the shaded part of Fig. 5, so as to get a sharp edge of 60°, more or less. We now get an efficient tool like Fig. 6; but in actual use we should not place it quite end on, as its chisel-like edge is too wide, but should so place it as to free about half (or more) from cutting. The same sort of tool with a rounded edge (Fig. 7) is really a very common one, and very useful; but, instead of having to file out a portion, the tool is bent up and then ground.

Now, supposing this tool, when new and laid in its place on the table of the slide rest, to be exactly the correct height, with its edge on the line of centres: it is evident that as soon as it needs grinding its edge will be too low, and then the shank requires to be packed up with bits of hoop iron, unless, as in some American rests, means exist for raising the tool-holder. To pack it up to the *exact* height is by no means easy. It is also an awkward tool to grind, as its shank is in the way. Hence, to facilitate grinding, the cranked form, Fig. 8, has been adopted; but here again packing becomes necessary as the edge gets lower, and this is the case with all solid tools of this kind which have also to be constantly re-forged as the end gets worn down. In large establishments, where such tools prevail and a tool-maker is at hand to renew the supply, these drawbacks are not so much felt; but with an amateur the case is different; and even in the largest workshops the solid tools are being very generally displaced by cutter bars; the prejudices of workmen being the sole bar to their universal adoption. Before speaking, however, of this modern substitute for solid tools, one other matter needs consideration—namely, the traverse of the tool sideways parallel with the work on which it is engaged. Let Fig. 9 represent in plan a piece of work which has been turned as far as the shoulder *b b*, D is the tool, such a tool as Fig. 6 laid end on.

The depth of cut is, of course, much exaggerated; but the shaving has now to be cut away till A is obliterated—the tool traversing towards the left hand. Now, although we gave a sharp edge to the front of the tool, and also a suitable clearance angle, it is evident that great force alone could advance the tool sideways against the shoulder *b b*, and it is here that a mistake in grinding is so commonly made. In Fig. 9 the absurdity is plain, solely on account of the exaggerated depth of cut; but with Fig. 10, or still more, with a round-end tool, Fig. 11, where the depth of cut is not exaggerated, the same error existing is not perceived, and many a tyro wonders why a tool ground with ample front clearance works so heavily and so badly. The truth is that the sharp edge is needed with requisite clearance both in front and at one side—the side next to the shoulder, which, in ordinary practice, is mostly the left. This appears easy; but, curiously enough, it is not so, for if we give a 3′ clearance all round the end and side, and then grind the tool at a given slope to make an angle of 60° at the front or extreme end of that curved edge, it will be 60° nowhere else, but blunter as it gets towards the sides of the curve. A compromise has, therefore, to be made. The part which is to take the lead must be rather less than 60°, or a little sharper, and that will give a fair average sharpness to the whole of the edge engaged. The beveling ought, therefore, to be in the direction of the arrow in Fig. 12, making *a* the sharpest point, and this is always to be the leading part of the edge, so that this tool is to be advanced invariably from right to left. The end of the tool is, for this reason, sometimes bent towards the left, like Fig. 13, or it is put on the tool holder so as to have the end turned a little in that direction; but in one way or the other the left side, if it is to lead, is made the sharpest. We shall always recognise it as the "leading edge," and it will become, in another sense, the prominent one when we speak of double edges.

The only remaining point to be alluded to in this kind of tool is the gliding of a shaving over its upper face. It is not unimportant; but if other details are attended to, this face will allow such a gliding motion to take place without undue resistance, which would break the edge of the tool if thin, or need greater power to carry it forward. To take now the *résumé* of the several points already treated, and upon which depends the efficiency of the tool, they are:—

1. The clearance.
2. The height of the cutting-edge.
3. The sharpness of the front edge.
4. The sharpness and clearance of the side edge.
5. The escape of the shaving by sliding over the upper face of the tool.

These are the essential points to be studied and thoroughly grasped, after which the following details will be also easily understood.

Remarking upon what is technically known as side-rake, which includes the clearance as well as sharpness of the tool on the side which is to lead, it is plain that we might consider this part, which is engaged in cutting the shaving from the shoulder, as a distinct edge, and the front one as a second. One would be the *leading edge*, to cut down the shoulder; the other would be the *following edge*, to cut the shaving from the cylindrical surface of the bar; and this surface would be good or bad according as the following edge did its work well or the contrary. In a round-edged tool the point at which the two edges meet would be indefinite; but we can just as easily grind them to meet at a given angle—as, for instance, in the tool numbered 14. This, which is the ordinary diamond-pointed cranked tool, is commonly used as, and also called, a straightforward tool, and is ground so as to give to each edge the same degree of acuteness. It does well enough for the purpose of roughing down a shaft, but it is plain that its real action is to cut a spiral channel or to trace a screwthread, fine or coarse, according to the rate of feed, and the result will not be a smooth surface, but one with a fine spiral line upon it, needing a flat-edged tool or the application of a file to finish it. Now instead of making and using the tool in this way, there is no reason why it should not be placed, so that the second or following edge shall at once leave a finished surface, needing no further application of any kind. (See Fig. 15.) The second edge, lying parallel to the cylinder, and acting as the chisel does on a cylinder of soft wood, will cut away the roughness left by the leading edge. But just as the soft-wood chisel is not placed *quite* parallel, to prevent a hitch, in, so neither is the following edge here to be so placed, but the right-hand corner of it must stand back a little. Here, again, the leading edge should be rather sharper than the following or finishing edge, as it has the most work to do; and, if it is keen, it will even tend to draw itself into cut, instead of requiring, as it otherwise would, to be hard driven by the slide rest. But here, again, moderation is needed, as it will, if too keen, draw in, hitch, and break. The extreme point at which the two edges meet may readily be conceived to be a drawback, rather than otherwise, to the tool; and so it is. The best way is to round it off slightly, as it generally gets broken. But it is well also to make this angle quite a large one—more than a right angle. Unless the tool is to work into a corner, it may be 120° or even more. The point will then be so much less acute that it will stand ordinary work without much risk of breakage. Even then, it should be rounded off on the oilstone.

This is the principle of double-edged tools which some think such a mystery; and even a round-edge tool is one in reality; but the meeting of the two edges is indefinite. It is, nevertheless, plain that as the shaving is cut from the shoulder as well as from the cylindrical surface—*i.e.*, in two directions, two edges are in reality engaged.

I have already remarked upon the necessity of packing up a tool each time it is ground, and also of repeatedly sending it to the forge; which last soon deteriorates the steel, and is seldom within the capacity of the turner himself, whether he be amateur or professional. Hence has arisen the cutter-bar—that is, a holder for short bars of steel—upon which last the cutting edges are formed by grinding alone, no forging being required. The bar forms the shank of the tool, and lies on the tool-plate of the rest; while the cutter itself, as it can be raised or lowered at pleasure, can be set to the exact height of centres with the utmost facility. This latter point alone should place the cutter bar in the foremost rank of lathe tools, as this accurate adjustment is hardly possible if the only means of attaining it are packing bars of hoop iron. Many designs of such cutter bars have been successively submitted to the test of practical use, and it is hard to determine which bears the palm. Some are for steel of round section, some for square bar, some for other less usual forms. With the exception of that now known as Haydon's, either the front or clearance angle is a fixed quantity, or the cutting angle. In the Smith and Coventry bar it is the first; in that used by Tangye and Co., it is the latter. In the Haydon bar, where, instead of one, there are three faces to be ground, all angles are variable at pleasure. At first sight it would naturally appear to any workman more desirable to have a cutter bar in which only one face of the tool needed to be ground, and hence the favour shown to that of Messrs. Smith and Coventry, in which the tool is a bit of steel of circular section, held so as to give at once the requisite clearance. The upper end of the round steel bar forming the cutter is ground off at any desirable angle, according to the nature of the metal upon which it is to be employed, and all is at once ready for work. The faults of such a tool have, however, been already pointed out—viz., the different degrees of acuteness of the elliptic cutting edge. The tool is otherwise one of great simplicity, and was, I believe, the first to be recognised as a practical workman's tool fit for the rough-and-tumble of a workshop. As a roughing-down tool there is very little, in fact, to be said against it; but Haydon's bar will do the same work better, and with less strain upon the machinery, and will leave the surface turned in a far more finished condition.

(*To be continued.*)

## THE INTERNATIONAL INVENTIONS EXHIBITION.—II.

### Naval Architecture.

AMONGST the groups which may be considered to be in tolerably complete order at the Inventions Exhibition is that entitled Naval Architecture, which is situated in the Queen's Gate annexe, and embraces ship and boat building, ships' fittings, and marine propulsion (including steering). The exhibits are rather mixed, it must be confessed, for while marine engines and nautical instruments are properly relegated to their more appropriate groups, there are several stands admitted here which in reality belong to other groups. The most notable exhibit is that of Sir W. Armstrong and Co., displaying a splendid collection of models and half-models of the specimens of naval architecture completed by this firm within recent years. Here one can see a full model of the Chilian cruiser *Esmeralda*, about which so much has been said in Parliament and elsewhere; models of the Austrian torpedo cruisers now building, which have twin screws, a ram, and a torpedo firing tube at the bow; models of the new Japanese protected cruisers, with bow and stern chasers, dumpy masts with tops for firing machine guns, and a speed of 18 knots. Besides these, there are many models of other war-ships, built for foreign nations, of the cable ships, like the *Faraday*, and what will interest Londoners especially, of new paddle steamers building for the River Thames Steamboat Company, and intended for employment between Battersea and Greenwich. These vessels are a decided improvement on anything yet seen on the river for passenger traffic between the points mentioned, for they are fast and commodious, with light and airy cabins, while they are practically unsinkable, as they are divided into compartments by water-tight bulkheads. Feathering paddle-wheels are to be used in these steamboats, and the passenger decks are carried well up, thus obtaining the greatest advantage for fine-weather traffic, and more comfortable saloons or cabins in the event of wet weather. Two exhibits which illustrate in a remarkable manner the great advances made in naval architecture are those of the Thames Ironworks and Shipbuilding Co., and of the Messrs. Laird. The former presents us with a full model and section of the *Warrior*, the first ironclad built in this country, and a fully equipped model of the *Benbow*, one of the Admiral class of line-of-battle ships which has recently been the subject of much discussion. We gave an illustration of one of these ships on p. 557, Vol. XXXIV.; but the *Benbow* has 10,000 tons measurement, with 9,000 indicated horse-power, and is estimated to steam at 16 knots. She has 18in. and 14in. armour, steel-faced, and carries two 110-ton guns, ten 6in. breech-loaders, twelve 6in. quick-firing guns, ten 4-barrel 1in. machine guns, and four 5-barrel ·45in. guns. The Messrs. Laird exhibit models showing the progress made in steamships during the last half-century, and notable amongst them is the new mail steamer *Ireland*, for the Holyhead and Kingstown mail service. This paddle steamer has 6,000 indicated horse-power with forced draught, and an estimated speed of 20 knots. She is 380ft. long over all, with a breadth of 38ft. and a depth of 19ft. 3in., and compared with the *St. Columba* of 1840 and the *Ulster* and sister vessels of 1860 well exemplifies the enormous strides which have been taken in recent years. The White Star Line show a model of the famous, and, perhaps, most successful (from all points of view) Atlantic steamer *Britannic*, a vessel which for many years has maintained a high speed with commendable regularity in her voyages. The exhibit of the Lords Commissioners of the Admiralty is a very poor affair, and is redeemed only by the fact that some full-sized sectional models of the armoured sides of a few of our most celebrated ironclads are included, showing the proportionate thicknesses of steel, iron, wood backing, and inner skin. Amongst the novelties may be noted the model of a sea-going torpedo boat, by T. Williams, 11, Queen Victoria-street, E.C., which is armed with two Nordenfeldt guns in shell-proof turrets and shields, two Hotchkiss machine guns, and provided with two tubes for discharging torpedoes. It is asserted that a vessel built to this design will steam for 1,600 miles at 12 miles an hour without coaling, although the total displacement is only 70 tons. The engines are calculated to develop 850 indicated horse-power, and the estimated maximum speed is 27 miles. Turning from the war ships we find a good display of boats of all kinds, including a specimen of the Nile boat used in the Soudan expedition, exhibited by Watkins and Co., of Blackwall. Amongst steam launches that shown by Simpson and Denisons, of Dartmouth, will attract attention from the compactness of the machinery, as it is fitted with one of Kingdon's compound engines, in which one valve supplies both cylinders. The space occupied on the floor is thus only that required by the large cylinder and valve-chest. The high-pressure piston-rod has a number of annular grooves, and the course of the steam is so arranged that a high-pressure gland is dispensed with. The Messrs. Yarrow show a model of the shallow-draught stern-wheel steamers used in the Nile expedition; and Pothonier and Co. show a model of a 1,000-ton steamer, specially designed for light draught, such as the steam colliers which now bring coals from Newcastle to Vauxhall. There are a variety of new inventions, more or less promising, connected with naval architecture, and the usual exhibits of boat-lowering and detaching apparatus, in connection with which may be noted the patent davits of Barry, Rees, and Co., of the Royal Naval College, Greenwich, which enable a boat to be swung outboard from the chocks with great facility. That is accomplished by semi-circular arms pivoted to the fixed davits, and worked by tackle. Capt. Heathorn shows his water-brakes and rudder propellers in working model, and Lieut.-Col. Hime a method of propulsion based on the swimming motions of flat fish. Four hinged plates worked by piston-rods descending through the hull present a series of changing inclined planes to the water, and when worked, give the idea of wave motion. There are other schemes of propulsion exhibited, all of which, however, would receive more attention if their capabilities had been demonstrated by practical trial. Apparatus for saving life at sea is exhibited in considerable variety, including the now well-known Copeman deck seats and tank rafts, models of lifeboats from the National Lifeboat Institution, and others; floating mattresses and other fittings designed to save life by enabling the possessors to keep at least their heads out of water. In this connection we may mention Hohnes's inextinguishable lifebuoy lights, which flare up when thrown into the water, and burn for about half an hour. Amongst minor inventions those exhibited by Mr. Balch, of Greenwich, deserve attention. He shows an electric sounder, which rings a bell in the captain's cabin the moment the lead drags on the bottom, the contact being made by the inclination of the head; a time-glass in a case coated with luminous paint, of use when heaving the log; and a breech-loading pistol or hand-gun for firing either signal or distress rockets. Mr. Boaz, of West India Dock-road, exhibits his tube stoppers, which have deservedly earned a high repute, as by a simple arrangement for expanding rubber discs, protected by copper shields, a tube can be stopped in two minutes without drawing the fires. He also shows a tube scraper and cleaner, consisting of two semicircular steel plates connected together in opposite positions at a little distance apart by webs which permit the passage of the refuse, and also act as guides to facilitate the return of the scraper when passed through the further end of the tube. By this arrangement the mere weight of the rod keeps the under-scraper down to its work, and forces the half disc on the upper side in contact with the top of the tube. An exhibition of this kind would scarcely be complete without specimens of anti-fouling compositions for coating the submerged parts of vessels, and Messrs. Kirkaldy, of West India Dock-road, add to the interest of their exhibit by showing a large collection of barnacles and other marine growths taken from the bottoms of iron vessels. Messrs. Suter, Hartman and Co., of Billiter-street, exhibit in connection with Rahtjen's composition some curious specimens of barnacles—one taken from a vessel sheathed with copper, and a piece of zinc sheathing showing the wear of the paint. This composition is used by the P. and O. Company, and has been applied to several of the best-known Atlantic liners. A working model of Baxter's anchor gear, with vertical windlass, which has been ordered for many of the new ironclads, deserves attention, as it dispenses with catheads and fish davits, and the anchors can be housed and stowed in about half the time necessary with the old appliances. Several good methods of stowing rowlocks are shown. In Robertson's the rowlock is carried with a stout stem in a fitting screwed to the gunwale, which has a vertical slot inboard. To stow, all that is necessary is to lift the rowlock up vertically until the thin part of the stem enters the slot, when it can be easily turned inboard. It is exhibited by Nunn and Co., St. George-street, E. In the device exhibited by Capt. Morris, of Lowestoft, the rowlock turns on a spindle and is kept in place by a simple plate catching into slots in the seating. He also exhibits sliding tholes, which are made to slip up and down in a casting, and cannot be lost, while they are out of the way when not required. Mr. Woosnam of Southend, also shows a stowaway rowlock, which is simply buried in the gunwale by lifting a plate behind it and turning it down sideways into the chamber provided. There are some curious exhibits which we cannot attempt to describe, as they are shown only in model form, including a water cycle, and a machine with buoyant wheels, which can be steered either on water or land; spiral screw propellers, the continuous or endless serpentine blade, and sundry supposed improvements in rudders. Steering gear is shown by one or two firms, and Messrs. Jessop and Co., of Sheffield, exhibit some splendid specimens of crucible cast steel in the shape of portions of vessels; Hall and Verity's patent flexible propeller shaft, and Turton's patent built-up crank shaft, showing the method of connecting the pieces and holding them together. If this group is a comparatively small portion of the Exhibition, it contains much to interest the general public, while those specially acquainted with the subject will find enough to occupy their attention for several hours.

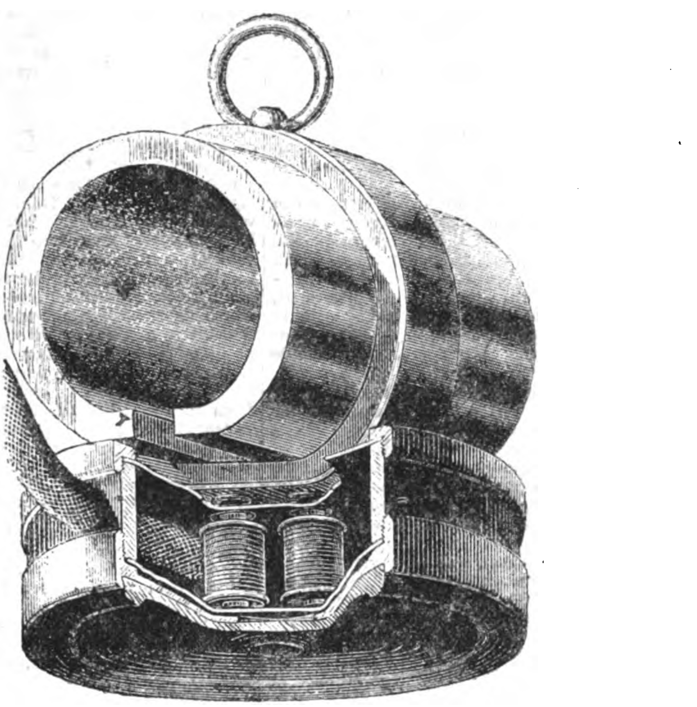
## INJURIOUS INSECTS AND COMMON FARM PESTS.

THE eighth report of Observations on Injurious Insects, by Miss Eleanor A. Ormerod, the hon. consulting entomologist of the Royal Agricultural Society, is a work which should be in the study of all practical agriculturists, and might with advantage be used as a lecture book in village schools. The annual loss from the depredations of injurious insects has long been known to many individuals, and if the assertion had been made they would probably have agreed that the aggregate loss, judging by their own, must have amounted to many thousands of pounds. Thanks, however, to the reports issued by Miss Ormerod, the fact is gradually being appreciated that the national loss from the work of insects and parasites is to be estimated by millions. The hop failure of 1882 alone involved an estimated loss of one million and three-quarters, while the turnip fly in 1881 did damage to the extent of over half a million. It may be contended that it is next to impossible to avoid occasional losses such as these; but the more intelligent amongst the agriculturists are beginning to understand that while they can do much personally, now that they know their enemies in their various shapes, a very great deal more might be done by combined action, and for that reason it may be hoped the report for 1884 will have a wide and far reaching sale. (It is published by Simpkin and Marshall, and can be had through all booksellers for 1s. 6d.) Already the correspondence has assumed such dimensions that Miss Ormerod has been obliged to make special arrangements in order that she may be able to attend to all inquiries, and to communicate with those who will make experiments and report results. The very first page of the "Observations" shows what can be done when the characteristics and life histories of the insects are known, for on it is depicted a male and female Winter Moth (*Cheimatobia brumata*), the caterpillars of which work so much havoc amongst fruit trees, especially the apple. The female has abortive wings only, and, being unable to fly, comes out at night and crawls up the trees, on the twigs of which she glues her eggs. It is obvious, then, that if some means of catching the female insect could be devised, that individual would, at least, be prevented from depositing eggs, and equally clear that by combined action the destructive Winter Moth might be stamped out of existence. One of Miss Ormerod's correspondents smeared the trunks of a number of apple trees, the blossom and leaves of which had been almost completely destroyed in previous years, and in a short time he had captured upwards of 500 females, and in the following summer was enabled to report that the trees were practically free from the "loopers," or caterpillars. Unfortunately it is not every insect that can be dealt with in so easy a manner; but there are many which can be almost stamped out by united action, and by repeated observations and experiments it is possible to learn how, at least, to fight them with some measure of success. As regards the wireworm, it has been recommended to leave infested acres fallow, ploughing frequently during dry weather, so as to prevent the growth of a single weed which will afford sustenance to the leather-jackets; but few can afford to do this. One of Miss Ormerod's correspondents made an unintentional experiment, which shows the benefit of late ploughing—that is, ploughing so late in the season that the wireworms are near the surface, and are consequently picked up by the birds. Wireworms go deeper and deeper as frost increases, and therefore the plough, when put into the ground as soon as the frost is out, brings none of them to the surface. Another correspondent has proved that Indian rape cake, so far from destroying wireworms, appears to prolong their destructive lifetime—the larval stage. With regard to the hop aphis, Miss Ormerod tells us that there does not appear to be any reason to doubt that the hop and the damson-hop aphis are merely slight varieties of one species; but if no very efficient destructive has been found, good results have followed the application of paraffin oil in any dry material by way of a dressing, and soft soap and mineral oil as a washing. Two useful notes refer to the Liver Fluke and the Warble Fly, or bot-fly of the ox. The marsh snails are believed to play the part of "host" to the Liver Fluke, and three figures of them are given, which will aid in their destruction; but more information is asked for on this point. The Warble Fly is unquestionably a source of great loss to the breeder of cattle and the dairy farmer, for the maggots bore into the skin of the beast and produce irritating sores, with a consequent loss of flesh and milk in summer, and a considerable depreciation in the value of the hide. A little table shows in a very direct manner the loss on warbled hides, for it appears that in seven weeks' supply to a firm of Birmingham factors out of 5,185 hides over one-third were warbled—the depreciation in value totalling up to £545. It is demonstrable that the maggot can be killed by any one of a number of simple remedies, but the common mercurial ointment will be found as effectual as anything, and need not cost more than twopence per head for all the cattle in the country. Tar or acetic acid is equally efficient. It is obvious that a little concerted action in the way of a combined attack on the pest for one year only would materially reduce the number of bot-flies; but it is equally obvious that a knowledge of the life-history of the insect should be widely spread before that concerted action can be brought about. For that purpose the "reports" of Miss Ormerod have a value which is not readily gauged; but it is certain that if every farmer and agriculturist would study the facts she places before her readers, and act upon the information given in the works she has already published, there would soon be an appreciable diminution in the numbers of many injurious insects, and, as we have pointed out above, the total extermination of some is within the limits of probability. It may be mentioned here that coloured diagrams of insects injurious to farm crops, prepared by Miss Ormerod for the Royal Agricultural Society, and suitable for use in elementary schools, can be had of the secretary, Hanover-square, W., at a cheap rate, and it would be of immense advantage if a set could be placed in every village school, and the teachers be induced to explain the life-histories of, and the importance of destroying, these noxious insects.

## LIQUID FUEL.

A PAPER on this subject, especially as concerns the application of liquid fuel to marine purposes, was read last Friday by Admiral Selwyn, at the United Service Institution. After reminding the older members of the institution that 20 years ago he drew attention to the enormous value of liquid fuel for the Royal and mercantile marine, Admiral Selwyn said that he had the mortification of seeing the subject, which was neglected by this country, taken up by other nations, especially by Russia. He stated that by the use of liquid fuel a vessel could carry twice as much power of propulsion as a vessel with coal; and he commented on the disadvantages which would arise to British vessels in having to meet opponents which could use double powers in escaping without the aid of resorting to a fuel station. He related the results of experiments, and proceeded to state that his object was to enforce a greater economy of fuel, which could be effected without any of that large expenditure often a necessary concomitant of radical changes. To burn liquid fuel instead of coal required no change in engines or boilers, and only such adaptation of the furnaces as could be readily carried out in each ship by her own artificers and engineers. At the same time, it removed the necessity for a whole army of stokers and coal trimmers. It enabled a ship to receive her fuel with the greatest facility at sea or in harbour, while proceeding under steam or even sail, was without nuisances of dust or ashes, and was not liable either to spontaneous combustion or deterioration by time, heat, or moisture. If the ship got on shore it could be run out to lighten her, or pumped out into lighters with a speed and facility unapproachable with coal; and, lastly, if, as he believed, 46lb. of water could be evaporated with 1lb. of fuel, full steaming for 24 days could be carried on where now it was limited to four. Thus each ship would be six times as effective as now. He declared that it was inconceivable how a nation like the British should have allowed this matter to remain dormant till another Power took it up, and he asked if it required a Caucasian to awaken this nation. In conclusion, he pointed out that the annual vote for the Navy amounted to about 18 millions, of which six millions would be devoted to the ships and their crews. If each ship was made twice as efficient—that was to say, could remain on her station twice as long as before by reason of a change in her fuel which gave her that power, this might be considered as affecting the value of the whole fleet to the extent of 12 millions per annum.

At a recent meeting of King's College Engineering Society a paper was read by Mr. Smith "On the Use of Petroleum as a Fuel." Petroleum, though found all over the world, has as yet only been successfully worked in America and Russia. Last year the output of crude oil from American wells was computed at 3,000,000 tons, ranging in price from 16s. to 32s. per ton, as against 1,130,000 tons from Baku, where it was worth from 3½d. to 2s. 6d. per ton. The Pennsylvanian oil seems to be found in strata always older than the carboniferous; while that in the Aspheron peninsula soaks tertiary sandstone, both, however being associated with metamorphism. The original source of the oil, however, is still unknown. Its use as a fuel in this country dates some twenty-three years back—a series of experiments both by private persons and at Woolwich, together with similar tests in America and France, giving most promising results, but with the effect that the price of crude oil was raised to a prohibitive figure. All this work had been done with crude oil, and it was only when it was found that the distillation, first of the lighter benzene products, then the illuminating oil, kerosine, and, finally, the separation of a valuable lubricating oil, left nearly 50 per cent. of refuse still valuable as fuel, and fuel only, that petroleum had its chance. According to the latest research Baku oil differs from American, not only in yielding some 60 per cent. of refuse instead of 15 per cent., but chemically, in that while the former is rich in paraffin, which renders it useless for liquid fuel, the latter has not yet been found to contain more than ¼ per cent. Russian petroleum refuse is a black-brown liquid of high viscosity, having an average specific gravity close upon 0·9, and an average theoretical evaporative power, from and at 202deg., of 21. The history of its use as a fuel during the last fifteen years shows that the oil was sprayed into the combustion chamber, first by an air jet in the easy burners of Bridges-Adams and Richardson, and then waste steam was added to the spray. Steam injection alone soon followed in the burners of Lentz, Karapetoff, and Hoffman, while a hollow flame supplied by a separate air injector with the oxygen necessary for the perfect combustion is the latest development, as in the burner of Anderson. The early experiments with boilers and fire-boxes designed for the comparatively moderate heat of coal soon showed by cracked plates and broken tubes the need of a fire-brick lining, and its important use as a store for heat was recognised later. First, a brick hearth, then a brick box, and



finally, in marine boilers, a complete flue lining was the result. Siemens has lately found that this lining may be broken into rings. Nobel, both for metallurgical and boiler firing, has used a trough burner, in which the oil is consumed direct without being pulverised. Experiments last year by Mr. Urquhart on the Grasi-Tsairtsyn Railway, show in locomotive practice, and the Caspian oil fleet in marine practice, its economic advantages. In England, where the crude oil exceeds £5 per ton, we must await the completion of the proposed 560 miles of pipe from Baku to Batoum on the Black Sea before refuse can be obtained.

## THE OCHOROWICZ LOUD-SPEAKING TELEPHONE.

THE following description and figure of the Ochorowicz telephone is extracted from *La Nature*. The problem of transmitting speech to a distance with sufficient intensity to be heard throughout, say, a large apartment has already been partially solved by Mr. Gower, and by Mr. Edison in his electro-motograph. Dr. J. Ochorowicz has recently presented a still completer and more perfect solution to the International Society of Electricians and the French Society of Physics. In the construction of his apparatus the inventor had especially in view the application of it to the auditorium of theatres, for which, in fact, it appears to be well adapted. The system, as a whole, includes a transmitter of variable resistance, the special arrangement of which Dr. Ochorowicz keeps secret; and of a magnetic telephone receiver, whose principal features are shown in the annexed engraving. This receiver, which is identical with Bell's, since it contains the three essential parts of that instrument (magnet, bobbin, and vibrating disc), differs from it, however, by important modifications of form, to which it owes its remarkable power. The magnet consists of a hollow steel cylinder, containing a longitudinal slit about a fifth of an inch in width. To the centre of this are fixed two small soft iron cores, upon which are placed two bobbins which are traversed by the undulatory current modulated by the transmitter. These two bobbins are inclosed in a sort of elastic metallic box, formed of two thin sheet-iron discs held parallel by their external edges upon a cylinder. The lower plate, which is firmly affixed to the magnet, contains two apertures, which allow the iron covers to pass freely. The magnetisation of these cores keeps the box thus formed in a state of tension, and the two ends of sheet iron slightly depressed and attracted toward each other. The effect of the variations in the undulatory current which is traversing the bobbins is to increase or diminish the magnetization of the cores, or, we might say, to cause the flow of force to vary. The box becomes compressed or dilated under the action of such variations, and vibrates in its entirety. Thus is explained the power of a receiver which, connected with Dr. Ochorowicz's special transmitter, has permitted speech, song, and music to be heard throughout the entire hall of the Geographical Society—a room capable of holding as many as 500 persons. The telephone receiver is capable of operating as a transmitter. Speech is, in this case, transmitted with less power, but it has still enough intensity to be easily and very distinctly heard at a yard or two from the receiving apparatus. In the microphone transmitter employed by Dr. Ochorowicz, heat appears to play a certain role, if we are to judge by the fact that all the experiments repeated before the International Society of Electricians, Feb. 4, succeeded except the last. Dr. Ochorowicz attributes this result to the fact that it is necessary for the microphone to be warm in order to be regulated. As soon as it ceases to be so, the regulation is destroyed, and is not effected again until a new heating occurs. Since, in the experiments mentioned, Leclanché piles were used, these became polarised after a certain time, and allowed the receiver to get cool. Such an inconvenience is remedied by the use of Daniell and Lalande and Chaperon piles, or of accumulators. It must be also noted that in Dr. Ochorowicz's system transmitting is done directly without the intermedium of an induction coil acting as a transformer.

## SNAP SHOTS IN PHOTOGRAPHY.

PHOTOGRAPHERS are indebted to a committee of the New York Amateur Photographers Society for the following table, which gives the conditions under which a reasonable degree of sharpness can be insured without focussing:—

To those who are using detective cameras, or taking "snap" shots, the following table will be of use, showing the number of feet beyond which everything is in focus when the equivalent focus of the lens and the relative diameter of the stop are known.

| Equiv. Focus equals | Stop. $\frac{f}{5}$ | Stop. $\frac{f}{10}$ | $\frac{f}{15}$ | $\frac{f}{20}$ | $\frac{f}{25}$ | $\frac{f}{30}$ | $\frac{f}{40}$ | $\frac{f}{50}$ | $\frac{f}{60}$ |
|---|---|---|---|---|---|---|---|---|---|
| 2in. | 7 | 3½ | 2¼ | 2 | 1⅓ | 1¼ | 1 | ⅞ | ¾ |
| 2½ | 10½ | 5½ | 3½ | 3 | 2⅓ | 2 | 1½ | 1¼ | 1 |
| 3 | 15 | 8 | 5 | 4 | 3½ | 3 | 2 | 1¾ | 1½ |
| 4 | 27 | 14 | 9 | 7 | 5½ | 5 | 3¾ | 3 | 2½ |
| 5 | 46 | 21 | 14 | 11 | 9 | 7½ | .6 | 4¾ | 4 |
| 6 | 60 | 30 | 20 | 15½ | 12½ | 10½ | 8 | 6½ | 5½ |
| 7 | 82 | 42 | 27 | 21 | 17 | 14 | 10¾ | 9 | 7½ |
| 8 | 107 | 54 | 36 | 27 | 22 | 19 | 14 | 11 | 10 |
| 9 | 137 | 68 | 45 | 34 | 28 | 23 | 18 | 14 | 12 |
| 10 | 167 | 84 | 56 | 42 | 34 | 30 | 21 | 18 | 15 |
| 11 | 202 | 101 | 67 | 51 | 41 | 37 | 26 | 21 | 18 |
| 12 | 241 | 121 | 80 | 61 | 49 | 41 | 31 | 25 | 21 |
| 13 | 283 | 142 | 94 | 71 | 57 | 48 | 37 | 30 | 25 |
| 14 | 328 | 164 | 109 | 83 | 66 | 56 | 42 | 34 | 29 |
| 15 | 376 | 189 | 125 | 95 | 76 | 64 | 48 | 39 | 33 |

As no two makers number their stops alike, and some do not number them at all, it is desirable to designate their stops in terms of the focal length of the lens. As an example of how misleading the information is obtained by giving the number of the stop, we would refer to the Dallmeyer lenses: Stop No. 3 in lens 1A is equal to $\frac{f}{32}$; stop No. 3 in lens 3D is equal to $\frac{f}{128}$. Here are stops of the same number, in lenses by the same maker, and yet one requires eight times the exposure of the other. We are confident that the small amount of trouble caused by designating our stops in terms of $f$ will be amply repaid by the aid it will give us in obtaining correct exposures.

## LIGHT AND COLOUR.

ON Tuesday, the 5th inst., Mr. C. V. Boys gave a lecture at the Royal Victoria Hall, Waterloo-road, on "Light and Colour." Colour was shown to be a property, not of coloured bodies, but of the light by which we see them. This was proved by a row of papers, coloured when seen by magnesium light, but black or grey by the light of the sodium flame. Various dyes, indistinguishable from each other, or from ink, by this yellow light, were used for painting on a screen. On the gas being turned up, bright colours became visible. The next step was to produce a spectrum, by bending aside a beam of white light by a prism. To show that this was not due to colouring matter in the prism, white light was reproduced by bending the beam back to its original direction with a second prism. The effect of red glass in stopping green rays, and of green glass in stopping red rays was shown, darkness being caused by sending the beam through both glasses. The action of the colours used in painting is like this. They reflect to the eye coloured light, because they have robbed the white light which fell on them of one of its constituents. Thus we get black by mixing paints of all colours together. When, however, we mixed coloured lights instead of paints, in such a way that one light is added to another, without anything being subtracted, we get white. This was done by rotating a disc with coloured sectors, so that before one colour had time to fade from a given part of the retina, another colour was presented to it. The result was that the disc appeared white. Mr. Boys ended by showing the effect on coloured objects of various brilliant monochromatic lights.

## ISOCHROMATIC PHOTOGRAPHY.*

By Fred. E. Ives.

IT is well known that the ordinary photographic processes do not reproduce colours in the true proportion of their brightness. Violet and blue photograph too light; green, yellow, orange, and red, too dark. For a long time it was believed to be impossible to remedy this defect; and even when it became known that bromide of silver could be made more sensitive to yellow and red by staining it with certain dyes, the subject received very little attention, because it was also known that the increase of sensitiveness was too slight to be of practical value in commercial photography. Dr. H. W. Vogel, who was one of the first, though not the first, to devote attention to this subject, announced, in 1873, that he had succeeded in making a yellow object photograph lighter than a blue or violet one, by using a silver-bromide plate stained with coraline, and exposed through a yellow glass. The plate showed no increased sensitiveness to red, and the experiment, though of considerable scientific interest, did not indicate a practically useful process.

In the spring of 1878 I became interested in this subject, and tried to discover a method of producing plates which should be sensitive to all colours, and capable of reproducing them in the true proportion of their brightness. I commenced by trying nearly all the colour sensitisers which had already been suggested, in order to learn which was the best, and then, if possible, why it was the best, as a guide to further research. Chlorophyl was the only thing I tried which was sufficiently sensitive to red to offer any encouragement in that direction; but the solution which I obtained was weak and unstable, and far from being a satisfactory colour sensitiser. Hoping to obtain a better solution with which to continue my experiments, I made extracts from many kinds of leaves, and found that a solution from blue myrtle leaves looked better and kept better than any other, and when it was applied to the silver-bromide plates they became remarkably sensitive, not only to all shades of red, but also to orange, yellow, and green. By placing in front of the lens a colour-screen consisting of a small glass tank containing a weak solution of bichromate of potash, to cut off part of the blue and violet light, I obtained, with these chlorophyl plates, the first photographs in which all colours were reproduced in the true proportions of their brightness. But my chief desire at that time was to realise a method of producing from any object in colours a set of three negatives, in one of which the shadows should represent the blue of the original, in another the yellow, and in another the red, in such a manner that transparent pigment prints from these negatives—blue, yellow, and red—would, when superimposed on a white surface, represent not only the lights and shadows, but also the colours of the object. This had already been attempted by others, who failed because their plates were not sufficiently sensitive to red and yellow. Having succeeded perfectly in my undertakings, I published my discovery in 1879, explaining how to prepare and use the chlorophyl plates, in connection with the yellow screen, for the purpose of securing correct photographs of coloured objects. So far as I know, nobody tried the process. Nearly five years later Dr. Vogel announced that, after eleven years of investigation, he had at last realised a successful process of this character, and that this new process of his was the "solution of a problem that had long been encompassed with difficulty." This publication attracted a great deal of attention, and gave me occasion to again call attention to my process, and point out that it was not only the first practical solution of this problem, but the only truly isochromatic process ever discovered. Dr. Vogel's new process was not only no better in any respect, but the plates were insensitive to scarlet and ruby-red, and, therefore, would not photograph all colours in the true proportion of their brightness.

---

* A paper read at a meeting of the Franklin Institute.

My method consists in treating ordinary collodio-bromide emulsion plates with blue-myrtle chlorophyl solution, exposing them through the yellow screen, and then developing them in the usual manner. The emulsion which I have employed is made with an excess of nitrate of silver, which is afterwards neutralised by the addition of chloride of cobalt; it is known as Newton's emulsion. I now prepare the chlorophyl from fresh blue-myrtle leaves, by cutting them up fine, covering with pure alcohol, and heating moderately hot; the leaves are left in the solution, and some zinc powder is added, which helps to keep the chlorophyl from spoiling. I have a bottle of this solution which was prepared about six months ago, and now appears to be as good as when first made.* A glass plate is flowed with the emulsion, and as soon as it has set the chlorophyl solution is applied for a few seconds, after which the plate is washed in pure water until smooth, when it is ready for exposure. My colour-screen consists of a small plate-glass tank, having a space of $\frac{3}{16}$ of an inch between the glass, filled with a solution of bichromate of potash about one grain strong. I place the tank in front of the lens, in contact with the lens-mount. The advantage of this tank and solution is that it can be more easily obtained than yellow plate glass, and the colour can be adjusted to meet any requirement. The plates require about three times as much exposure through the yellow screen as without it, and may be developed with the ordinary alkaline pyro-developer. In order to illustrate the value of this process, I made two photographs of a highly-coloured chromo-lithograph, representing a lady with a bright scarlet hat and purple feather, a yellow-brown cape and a dark-blue dress. One, by the ordinary process, represents the blue as lighter than the yellow-brown, the bright scarlet hat as black, and the purple feather as nearly white. The other, by the chlorophyl process, reproduces all colours in nearly the true proportion of their brightness, but with a slight exaggeration of contrast, produced purposely by using a too-strong colour solution in the small tank.

I also made two landscape photographs, one by the ordinary process, and the other by the chlorophyl process, exposing them simultaneously. In the ordinary photograph, distant hills are lost through over-exposure, yet the foreground seems under-exposed, and yellow straw stacks and bright autumn leaves appear black. In the chlorophyl photograph, the distant hills are not over-exposed, nor is the foreground under-exposed; the yellow straw-stacks appear nearly white, and bright autumn leaves contrast strongly with the dark green about them.

To test the relative colour-sensitiveness of plain emulsion plates, plates stained with eosine, and plates stained with the blue-myrtle chlorophyl, I exposed one of each kind through the same yellow screen, giving each five minutes exposure, on the same piece of copy, which was the chromo-lithograph already described. The plain emulsion plate showed only the high lights of the picture, after prolonged development. The eosine plate was under-exposed, but brought up everything fairly well except the scarlet hat, which came up like black. The chlorophyl plate was over-exposed, brought out all colours better than the eosine plate, and gave full value to the bright scarlet of the hat, the detail in which was beautifully rendered.

Dr. Vogel advanced the theory that silver-bromide is insensitive to yellow and red, because it reflects or transmits those colours; and that it becomes sensitive when stained, because of the optical properties of the dyes. He afterwards admitted that only such dyes as are capable of entering into chemical combination with the silver-bromide proved capable of increasing its sensitiveness to colour, but he held to the theory that the optical properties of the compound were the cause of its colour-sensitiveness.

I have shown that the colour-sensitiveness can be produced by treatment with an organic compound which has none of the optical properties characteristic of dyes; and that chlorophyl, which absorbs only red light, greatly increases the sensitiveness also to yellow and green. There is, therefore, good reason to doubt if the colour-sensitiveness is ever due to the optical properties of the dye or combination. Attempts have been made to produce isochromatic gelatine dry plates which, while many times more sensitive to white light than my chlorophyl plates, shall also show the same relative colour-sensitiveness. Such plates would be very valuable but for one fact; it would be necessary to prepare and develop them in almost total darkness. Gelatine bromide dry plates extremely sensitive to yellow, but comparatively insensitive to red, might be used to advantage in portrait and instantaneous photography, because they could be safely prepared and developed in red light; but when truly isochromatic photographs are required, the time of exposure must be regulated to suit the degree of sensitiveness to red, which cannot safely be made greater than I have realised with my chlorophyl process.

## SCIENTIFIC SOCIETIES.

### ROYAL ASTRONOMICAL SOCIETY.

THE May meeting of the Society was held at their rooms, Burlington House, on the evening of Friday, the 8th inst., Edwin Dunkin, Esq., F.R.S., president, in the chair.

Prof. C. H. Brewitt Taylor, of Foo-Chou Arsenal, China, was balloted for and duly elected a Fellow of the Society.

A paper by Mr. R. A. Proctor was read, entitled "Five Orders of Meteor Streams or Comets." He referred to the importance of Mr. Denning's discovery that certain groups of meteors have stationary radiant points, which do not move amongst the stars as the earth passes round the sun. At first he doubted whether the discovery could be real, because the inference that necessarily followed was so startling—viz., that the motion of the earth in its orbit round the sun is as rest compared with the velocity of these meteors. Without assuming that the positions of the radiants can be determined with the precision claimed by Mr. Denning, it is certain that the meteors from the long-lasting radiants must travel at the rate of hundreds of miles per second. We must look for the source of these tremendous velocities to the bodies of the giant suns distributed in space. There are five sources from which the meteor swarms encountered by the earth may be supposed to spring: First, there are those which may be supposed to have sprung from the terrestrial planet when in a sunlike state; secondly, those springing from the giant planets when in a sunlike state; thirdly, those springing from our own sun; fourthly, those springing from suns of the same order as our own sun; and fifthly, those springing from giant suns of the first order.

Mr. Ranyard said: It is not necessary to suppose that the enormous velocities of the bodies coming from Mr. Denning's stationary radiants must be due to the velocity of projection. Matter thrown out from a star would have the proper motion of the star, as well as the velocity with which it is ejected, and the proper motions of some of the stars must be very large compared with any planetary motions; for instance, the star 1830 Groombridge, in the Great Bear, which has a proper motion of 7" per annum, has hardly any appreciable parallax. If we accept Mr. Denning's observations as proving that these radiants do not shift one degree in the heavens, it will be necessary to assume that the meteors from these stationary radiants encounter the earth's atmosphere with a velocity at least fifty times as great as the earth's orbital velocity.

Col. Tupman: We must all admire the fertility of Mr. Proctor's speculations; but it is quite certain that no such velocities are observed. The meteors from Mr. Denning's stationary radiants certainly do not move with a velocity anything like fifty times as great as the velocities of the meteors from the chief annual radiants which move approximately with parabolic velocities.

Mr. Ranyard: Has Col. Tupman any evidence with regard to the velocity of meteors from any one of Mr. Denning's fixed radiant points? No doubt there are many simultaneous observations made by observers in different places, of boloids and large meteors which have enabled their velocity within the atmosphere to be calculated, and from theoretical considerations the velocity of meteors belonging to the planetary swarms cannot differ very much from parabolic velocities. But these swift meteors from fixed radiants must be consumed very high in the atmosphere, and I do not know what evidence there is to show that they cannot have these enormous velocities.

Col. Tupman: There is a certain amount of evidence to be deduced from comparing the angular velocities of meteors from different radiants. If the meteors from two radiants have the same velocity, and were stopped at the same average height, the average angular velocity would be pretty much the same. There are certain radiants from which slow-moving meteors come, and others from which the motions are more rapid; but there is nothing like the difference that would correspond to a velocity fifty times as great in one case as compared with another. At 90° from the radiant the average angular velocity appears to be always about the same. If there were any with double or treble velocities, it would be noticed at once. At some little distance from the radiant the speed is usually not too great to permit of your following the meteor with your eye.

Mr. T. K. Mellor: I would suggest that it would depend very much on the part of the star from which matter was expelled, whether in the front or at the rear with respect to its proper motion, whether the meteor shot out would have the proper motion of the star, or the proper motion minus the velocity with which it was ejected.

Mr. Stone explained a paper on the Right Ascensions of the Cape Catalogues for 1850, 1860, and 1880. He said that Mr. Downing had instituted a careful comparison between the Cape Catalogue of 1880 and the Melbourne Catalogue of 1870. This comparison showed close agreement; but when comparisons were made between the Cape Catalogues of 1850 and 1860 and the Melbourne Catalogue, the differences of places due to the proper motions of the stars came in, and the comparison was not therefore trustworthy. The result of the comparison of the 1850 Catalogue with the 1880 showed that the Right Ascensions were one-tenth of a second too small, while the 1860 as compared with the 1880 gave them as too big. Taking out those stars which had a known proper motion, and making allowance for it, he had reduced the difference to five hundredths of a second in the one case, and three hundredths in the other.

Mr. Downing thought that the error in the comparisons due to proper motions might be neglected, for in comparing the 1850 and 1880 Catalogues, he had made use of the places of 3,368 stars, and with such a large number it must be supposed that the errors introduced by + proper motions would nearly correspond to those due to − proper motions.

Mr. Knobel read a paper by Mr. John Maguire on total solar eclipses visible in the British Isles from A.D. 878 to 1724. The paper enumerates all the eclipses in which the path of totality has touched the British Isles, and it contains tables showing the width of the shadow path. London has been twice visited by total eclipses during the period dealt with, first in 878 and again in 1715, Dublin twice, and Edinburgh five times. The Moon's shadow has fallen during the period named on every spot in the British Isles, except a small place on the coast of Ireland.

Col. Tupman read a paper by Mr. Denning on a peculiar variety of meteors observed on the morning of April 20. As Mr. Denning was watching the progress of the Lyrids he saw a remarkable meteor projected apparently on the stars ε and δ Lyræ; it rose upwards with great rapidity. It appeared about equal to a star of the third magnitude. Its chief peculiarity was its marvellous velocity. It appeared to be in the air only a few yards distant, and it must have travelled over 16° on the background of the sky in the twentieth part of a second.

The ordinary meeting then adjourned, and the meeting was made a special meeting, in accordance with the notice given to Fellows.

The Earl of Crawford, in moving the first resolution, said: The proposal which I have to bring forward has occupied the attention of certain members of the society for a number of years. It has been felt that those Fellows of the society who do not live in or near London are, to a certain extent, under disability in not being able to vote in electing the president and council of the society. It seems to me that the accident of their living at a distance from the metropolis should not disqualify them from taking a part in selecting the governing body of the society, whose action may have an important influence on the welfare of astronomy. I am in no way affected myself by this disability which lies on our country and foreign Fellows, for I usually manage to be present at our elections. I therefore feel that I am not actuated by any personal motive in proposing this alteration of the by-laws. I am only actuated by a desire for the benefit of the society, and a wish that our foreign Fellows, of whom we now have a great number, should take a greater interest in the affairs and action of the society. Great attention has been given to the wording of the resolutions; but I see that there is a printer's error in the first resolution, from which it might be supposed that a Fellow might hand in more than one list. It should run, "A list," not "lists," "handed to the scrutineers of the ballot on behalf of any Fellow not present at the meeting shall be accepted, if duly verified by the signature of the absent Fellow." It is proposed to add these words at the end of by-law 12.

---

* I originally recommended chlorophyl extracted from dried leaves, because I had not learned how to preserve the solution for more than a few weeks, and at some seasons it would be difficult, if not impossible, to obtain fresh leaves. The tea organifier which I recommended is also a colour sensitizer, and when it is used in connection with the chlorophyl from dried leaves the plates are as sensitive to red as can be safely prepared and developed in the light of an ordinary photographic "dark-room." Plates prepared with chlorophyl from fresh leaves do not require treatment with the tea organifier to secure this degree of sensitiveness. Recently I have used the tea organifier and some other sensitisers, in connection with the solution from *fresh* myrtle leaves, and in this way have produced plates having such an exalted colour sensitiveness as to be unmanageable in ordinary "dark-room" light. Possibly, such plates might be prepared and developed in total darkness, by the aid of suitable mechanical contrivances; but I am not sure that they would work clear even then, because they appear to be sensitive to heat as well as to light.

Mr. Mattieu Williams seconded the motion.

Mr. Brett said: Lord Crawford has made one slight mistake. He has said that country members are disqualified from voting. They are not disqualified. They are only debarred by reason of their not taking the trouble to attend. When they entered the society they did so on the understanding that they would not be allowed to vote unless they were present at the meetings.

The President said: Before the discussion proceeds, I think it may be well for me to explain the action the council has taken in this matter. I think I may say that they are desirous that something to the effect of this motion should be passed to-night. At the same time they think that every precaution should be taken to prevent any irregularity in voting, and, therefore, that the lists should be forwarded by post in a closed envelope under cover of a letter signed by the Fellow, and addressed to the scrutineers of the ballot. It would not, in my opinion, be beneficial to the society that country Fellows should be allowed to send their lists to other Fellows who would be present at the meeting, and these other Fellows might hand them to the scrutineers. I have had some 40 years' experience of this society, and I hope, therefore, you will allow me to say that I believe we shall be doing the society a great deal of harm unless the precautions I speak of are embodied in the resolution.

Mr. Chambers said that he believed a large number of the Fellows of the Society would welcome the concession which had been made by the president on behalf of the council. At the same time, he hoped that Lord Crawford would not withdraw his motion, except on a very clear understanding that the council would pledge itself to propose, at an early meeting of the Society, such an amended resolution as had been suggested. At present the great bulk of the Fellows were practically disfranchised. There were 500 Fellows of the Society, and instead of the great bulk taking part in the election of the council, it practically amounted to 20 Fellows joining with the council to elect 20 who had already been selected by the old Council. The result was that the council of the society did not command the unreserved confidence which it otherwise would. In evidence of that he would point to the fact that the society did not now attract to itself the important papers which it attracted fifteen or twenty years ago.

Mr. Beck hoped that the change would not be made, for he felt that it would be throwing additional power into the hands of the council, and that the council list would always be adopted by absent Fellows.

Sir Edmund Beckett said that the proposal of the President seemed to him to make very little difference. It was merely a matter of machinery as to how absent members should be allowed to register their vote. He could hardly understand how there could be any dissentients to the proposition. It should be remembered that in voting for the council there was never any debate, and there could be no debate, about a person's character. He could see no reason against the proposition, except the jealousy of those who lived in London against those who did not live in London. He thought there was force in what had been said about the greater interest that would be taken in the affairs of the Society by absent Fellows, and he feared that he must endorse what Mr. Chambers had said about the evident decline in the interest that was taken in the affairs of the Society compared with what used to be. This was a practical reason why, if it was wished to keep the Society flourishing, they should pass this resolution.

Mr. Ranyard said that it was important that the resolution should be passed at that meeting, and should not be referred back again to the council. He thought that no great harm would be done by substituting the word "posted" for the word "handed," "to the scrutineers," though he did not see that much would be gained by it in practice, for any country Fellow would be able to send his balloting paper to anyone in London who undertook to canvas for votes, and the London Fellow might then post the lists to the scrutineers instead of handing them, and he saw no advantage in making the country Fellow sign the outside of an envelope rather than sign the balloting list itself.

Dr. Schuster said that he thought no change should be made in the method of voting. The alteration which was now proposed was only a little less objectionable than the first proposition. It would give rise to touting at the elections, and entirely alter the character of the society. A man ought certainly not to be allowed to vote without having heard the arguments which could be adduced by either side, and which might entirely change his opinion. Unless Fellows took sufficient interest in the society to attend the meetings, their votes had better not be received. He had himself come up to London after delivering three lectures in Manchester that day, on purpose to attend the meeting and vote against the proposed alteration.

Capt. Noble said that he had noticed that when there was any election for officers and council going forward there were quite a different set of faces to be seen from those which were to be seen at the ordinary scientific meetings of the society. He thought it advisable that people who took so much trouble to attend the business meetings of the society should not be allowed to outvote those who attended the ordinary scientific meetings. He thought that the proposed alteration would put everybody on the same footing, and he hoped that it would be adopted.

Mr. Knobel said he thought that a grievance had existed, and that it would be better to remedy it by allowing absent Fellows to vote; but their lists must not be signed, or it would be a distinct departure from the by-laws, which require that the election should be by ballot, that is by a secret vote. The list might be folded up and then placed in an envelope, which should be signed by the Fellow and addressed to the scrutineers.

After some discussion the following alteration was adopted by Lord Crawford and the seconder of the motion, "A list addressed and posted to the scrutineers of the ballot on behalf of any Fellow not present at the meeting shall be accepted if duly verified by the signature of the absent Fellow on the envelope." The motion was put to the meeting, and carried by a large majority.

Lord Crawford then proposed the second resolution — viz., that at the end of by-law 53, the following words be added, "Fellows of the Society may vote on the business brought before annual general meetings and special general meetings, either personally or by proxy." Lord Crawford said what he had said before with regard to absent Fellows voting upon the election of the council; applied in the same manner with respect to voting on all other subjects. The proposal, if adopted, would not allow a proxy to be appointed by an absent Fellow to vote for him on any indefinite subject of which notice had not been given for the by-laws required a month's notice to be given to all Fellows of the business which would be brought before annual general meetings and special general meetings.

Mr. Newall seconded the motion.

After some discussion it was put to the meeting, but was lost by a small majority, 35 being for the motion, and 38 against it. Several Fellows present abstained from voting.

It was decided that the evening meetings should continue to be held at eight o'clock.

**Explosion of a Safety Boiler.**—A Board of Trade report has been published on the explosion of a Howard safety boiler, causing the death of one man. Mr. T. W. Trail says:—"This explosion appears to have been caused by the local overheating of one of the wrought-iron tubes. It is thought that sediment collected in the interior of the tube and prevented the water from getting into contact with the iron; consequently it got hot, which rendered it unfit to sustain the internal pressure, and the explosion occurred. Water-tube boilers have not been very favourably looked upon in this country, and when used the feed-water should be practically free from deposit; and there are comparatively few places where such water is available for feeding boilers. It is essential that the heating surfaces of all boilers be kept clear, but where tubes are used, and almost in the fire, unless great care be taken, deposit is sure to collect, and in this case unfortunately, it has apparently caused the death of one man."

M. MORIZE, of Rio de Janeiro, has devised a selenium apparatus for measuring the relative intensities of the rays of the sun at different altitudes above the horizon. It consists of a selenium cylinder prepared according to the plan of Professor Graham Bell, thirty-eight discs of copper being isolated from each other by smaller mica discs, and the edges filled in with selenium. It is insulated by glass supports inside a glass envelope from which the air has been exhausted. The vessel is elevated in a place where surface reflection does not reach it, and the axis is placed parallel to the axis of the earth, so that the rays of the sun fall normally on the selenium cell and illuminate the same surface. Its position can be altered to keep up this condition from day to day. A constant current traverses the selenium and a galvanometer in circuit with it. From darkness to the most intense radiation of the sun is the range to be observed, and a scale is graduated accordingly.

# SCIENTIFIC NEWS.

THE death is announced of the Rev. James Charles Clutterbuck, M.A., the "father of hydro-geology." Possessed of an extensive knowledge of geology, he was a recognised authority upon all questions relating to wells and water supply, and gave his opinion as freely as it was sought. The deceased gentleman, who had reached the ripe age of 84, was a member of the Thames Conservancy, and for 55 years vicar of Long Wittenham, Berks.

Prof. Panum died recently at Copenhagen, where he filled the chair of physiology. He was president at the last International Medical Congress, and has been known for years as one of the ablest workers in the field of physiological science. He exhaustively treated the subject of transfusion of blood, and his treatise on embolism is a recognised classic. Prof. Panum long ago investigated the virus of septicæmia, and arrived at the conclusion that it was independent of the agency of living organisms. Dr. Panum was 65 years of age.

The deaths are also announced of Dr. Nachtigal, the African explorer, and of Dr. Karl Köppritz, Professor of Geography at Königsberg, and a well-known "reporter" on the progress of geophysics and African exploration.

Dr. Theodor von Oppolzer, of Vienna, announces the early publication of a very extended list of the dates of solar and lunar eclipses, which has been prepared under his direction. There are 8,000 of the former and more than 5,000 of the latter class of phenomena, all included between the years 1207 B.C. and 2161 A.D.

Mr. J. E. Gore has sent us a copy of his "Catalogue of Suspected Variable Stars," a paper read before the Royal Irish Academy, and reprinted from the *Proceedings* of that body. The catalogue has been compiled from various sources, and contains some stars which are no doubt really variable, but which need further observations to place their variability beyond question. The catalogue is accompanied by a map in which known variables are marked in red, and the suspected stars in black. It will be very useful to those engaged in this branch of astronomy.

The April part of the *Journal* of the Liverpool Astronomical Society contains, amongst other papers, one entitled "Some more Evenings in Town with a 3¼in. Telescope," by the Rev. J. H. Honeyburne, which will be read with interest by many observers.

It is stated that, in consequence of his health, Prof. Huxley is about to withdraw from some of his most active employments, in order to recruit his strength by a prolonged period of rest.

Dr. Frankland intends to resign the Professorship of Chemistry in the Normal School of Science and Royal School of Mines at the end of the session.

Mr. Omond, the superintendent of the Ben Nevis Meteorological Observatory, gave a summary last week, before the Royal Society of Edinburgh, of the results of his two years' observations on the summit of the Ben. Among other subjects alluded to were the rarity of thunderstorms; the range of temperature (the thermometer scarcely, if ever, fell below 10° Fahr. in winter); the daily variation in the average velocity of the wind, which is greater at night than during the day; the direction of the winds, which is almost always different from that at low-level stations; and the amount of rainfall, which greatly exceeds what had been expected. Mr. Omond thinks that the establishment of a fully equipped observatory at the foot of the mountain is likely to be of great service to meteorological science.

It is proposed to establish a naturalists' field club for Hampshire, and a meeting in support of the proposition will be held at Winchester on the 28th inst. Mr. E. Westlake, of Fordingbridge, Salisbury, is the hon. sec.

The spring meeting of the Iron and Steel Institute was held last week, when the inaugural address was delivered by Dr. Percy, the president, the Bessemer gold medal for the year presented to Prof. Richard Akerman, and several papers were read and taken as read. In the course of his address the president made some timely remarks about technical education, in the course of which he said he fully agreed with his friend, Mr. I. Lowthian Bell, that our metallurgists were not so incompetent as certain persons would lead the public to believe, and that with respect to skill in manipulation, ability to direct operations, and knowledge of the principles of their art, they had no reason to fear foreign rivals. Technical knowledge was acquired in the only school where it could be acquired—viz., the establishments where metallurgical processes were conducted on a large scale. It was, he thought, a matter for regret that there had been indiscreet attempts to imbue artisans with the notion that the one thing needful for them was technical education, and that this was a certain means of benefitting them all alike. Of the advantage of special instruction adapted to special artificers, in addition to what they acquired in the ordinary practice of their respective arts, there could not be two opinions; but, on the other hand, there were a large number of artisans who would not be rendered more competent by instruction of that kind. It was a gratifying sign of the times that the value of special instruction to at least a large class of artisans should be generally recognised, and that by the munificence of private individuals admirable institutions for imparting it had been established in several of our great centres of industry. Dr. Percy referred to the important question whether malleable bar iron, as used in the construction of many railway bridges in the United States, acquires in time a crystalline structure to such an extent as to become dangerous, and also mentioned the daily increasing danger from the telegraph and telephone wires now stretched over our towns. These are at last it seems to be under some kind of control; but Dr. Percy thinks that not until a political dignitary happens to be decapitated or strangled, will efficient measures to protect the public be taken.

It will interest many of our readers to know that the great influence machine which Mr. Wimshurst made for the School of Science is to be seen in the International Inventions Exhibition (South Central Gallery). Mr. Wimshurst also exhibits a smaller machine (18in.) of the latest design, and a continuous electrophorus (plates with many sectors). To assist amateurs, the parts in these machines are exhibited separately, and if our readers will state, through the Query columns, any points on which they have a doubt, Mr. Wimshurst will reply, and add to the exhibit any other feature which may be requisite to make the construction of these influence machines clear.

Another machine which has excited some little attention from our readers will be found in the north end of the Queen's Gate Annexe, where in Group VI., No. 836, is what is called an "improved form of tricycle," the exhibitor being Edwin Sturge. The machine shown differs in construction from that illustrated on p. 291, Vol. XXXIX., but no doubt it will go just as well.

The International Cholera Conference will commence its labours to-day in Rome. Sir W. G. Hunter, M.D., and Dr. T. Thorne represent this country, with Sir J. Fayrer and Surgeon-major T. Lewis for the Indian Government.

Dr. R. Koch has been appointed professor of hygiene in the University of Berlin.

A portion of the former Industrial Academy in the Klossterstrasse, Berlin, is to be fitted up as a permanent hygienic museum, at a cost of £3,000, a similar sum being spent on the arrangement of a laboratory.

The *Journal* of the Anthropological Institute for May contains the address delivered by Prof. Flower on retiring from the presidential chair. The address should be read by all who wish to understand the classification of the various forms of the human species.

Signor Narducci, the distinguished Italian palæographer, has presented to the Accademia dei Lincei some documents proving that negotiations were carried on between Sixtus V. and the Republic of Venice in reference to cutting a Suez Canal. It appears that the project was abandoned from the fear that the channel would soon become obstructed by sand, in consequence of a difference in the level of the two seas.

Large numbers of salmon fry have been recently placed in the Tay and tributary streams. The fry were obtained from the hatchery at Dupplin, belonging to the Tay Fishery Board. Previous experience had shown that a temperature of 45° hatched the fry in about 64 days, and they consequently had to be turned into the river too early in the season. Colder water has since been used, ranging from 37° to 45°, and the average time of hatching has been extended to 108 days. The total loss of ova and fry from 315,000 eggs was a little more than one per cent. Fifteen thousand fry have been retained at the hatchery, and the remainder have been distributed as mentioned above.

A new automatic brake has been tried at the Edinburgh works of the North British Railway Co. It is stated to meet all the requirements of the Board of Trade, and not to leak off until released by the driver, while it prevents skidding.

A new note has been prepared by the Bank of Scotland under the directions of Prof. Crum Brown and Dr. J. Gibson. It is printed in three colours—brown, yellow, and blue, in order to resist attempts at reproduction by photography.

M. Olzewski, in a note communicated to the Academy of Sciences of Paris on the liquefaction and solidification of formene and nitric oxide, says that by preparing products free from acetone and hydrogen, he has succeeded in obtaining a white snow-like mass. M. Cailletet used these substances in obtaining the liquefaction of oxygen.

# LETTERS TO THE EDITOR.

## NEW RED SPOTS ON JUPITER.

[24219.]—IN the morning twilight of Sept. 27, 1883, Mr. Franks discerned a "faint elliptical spot" just above the S. equatorial dark belt of Jupiter. On the drawing which accompanies his letter (21900) in the ENGLISH MECHANIC for Oct. 12, 1883, p. 126, he depicts this spot as slightly past the central meridian at 5h. a.m. From the position of this object I estimate it to have been central on September 26 at 16h. 54m., or 6m. prior to the time at which his sketch was taken. The spot is further described by Mr. Franks as "a pale, insignificant patch, devoid of colour or strength of outline." On the date of your correspondent's observation the apparent diameter of Jupiter was about 33″, and the major axis of the spot subtended an angle of about 5″, so that it would be some 14° long and occupy 23 minutes crossing the meridian. It followed the red spot 1h. 59m. in the same parallel of latitude.

Now this spot detected by Mr. Franks has developed into a very conspicuous and interesting feature. It has been seen by many observers, and is several times referred to in recent numbers of your journal. I have been comparing the observations, and there is not the slightest doubt that they refer to one and the same object, which has not only retained precisely the same form as when first seen, but has, during the present opposition, exhibited a deep red colour even more intense than the old spot in its best days.

In the ENGLISH MECHANIC for Feb. 13, 1885, p. 517, Mr. E. Miller says (23818):—"Last night (Feb. 2) whilst observing Jupiter at 22h., a spot was seen on the south equatorial belt close to its southern edge. In size and shape it is the exact counterpart of the great red spot, but differing in colour, it being a deep cherry red. It was on the central meridian at 22h. 45m."—(I suppose this means 10h. 45m.; the premature use of the new time by certain of your correspondents will cause endless complications). On Feb. 2 the red spot was on the C.M. at 8h. 58m., so that Dr. Miller's spot followed it by 1h. 47m.

Mr. J. M. Offord also refers to the spot (ENGLISH MECHANIC, Feb. 20, 1885, letter 23846. He says, on Feb. 11:—"Following the red spot on the southern edge of the reddish belt, which is now the most conspicuous marking on the globe, there are several dark spots of a crimson lake colour, the first of which comes into view about an hour after the red spot has crossed the meridian."

In the *Astronomical Register* for April, 1885, p. 95, Mr. N. E. Green writes: "Following the red spot in the same latitude there is an unusually definite mark, which commenced as a straight grey line, and is now increased in size and becoming red. Its size is about half the length of the old red spot, by about one third of its width, and is on the meridian about an hour after the red spot." In the same journal for May, p. 116, Mr. Green supplements his preceding remarks by saying: "There is now no doubt about the character of the mark following the great red spot, to which reference was made in the last number of the *Register*: it is evidently a small one of the same kind. It was observed this evening (April 20) under favourable circumstances. The old red on the meridian about 7.30, and the new red following about 9h., so there is 1h. 30m. between them, and the new spot is best seen when the old one is disappearing at the limb. The position of the new spot is on the polar edge of the southern belt, and its size about half the length by one-third the breadth of its forerunner.

I now come to my own observations. Early in the present year I began to notice dark elliptical spots on the faint grey belt just outlying the great southern belt. I did not record them particularly, however, until the end of March, and then I began watching the most prominent one. It came to the central meridian at 9h. 20m. on March 27th, and I had previously noted the red spot central at 7h. 32m., so that the smaller spot followed the red 1h. 48m. I obtained many further observations in April, and estimated the spot as 14° long. Its position was 66° E. of the old red spot, and a careful comparison with Mr. Franks's observation of Sept. 26, 1883, showed the absolute identity of the two markings.

The following are the only observations I have seen or obtained up to the present time. I shall be very glad to receive notice of any others from your astronomical contributors:—

| Date. | New Red Spot on C.M. | Follows old Red Spot. | Observer. | Telescope. |
|---|---|---|---|---|
| 1883— | h. m. | h. m. | | |
| Sept. 26 | 16 54 | 1 59 ± | W. S. Franks.. | 11¼in. refl. |
| 1885— | | | | |
| Feb. 2 | 10 45 | 1 47 | E. Miller...... | 10¼in. refl. |
| Feb. 11 | — | — | J. M. Offord .. | 5¼in. refr. |
| Mar. | — | 1 0 ± | N. E. Green .. | 18in. refl. |
| Mar. 27 | 9 20 | 1 48 | W. F. Denning. | 10in. refl. |
| Apl. 6 | 7 38 | 1 50 | ,, | ,, |
| ,, 13 | 8 29 | 1 51 | ,, | ,, |
| ,, 17 | 11 46 | 1 52 | ,, | ,, |
| ,, 18 | 7 37 | 1 54 | ,, | ,, |
| ,, 20 | 9 13 | 1 51 | ,, | ,, |
| ,, 20 | 9 20 | 1 30 | N. E. Green .. | 18in. refl. |
| May 2 | 9 10 | 1 49 | W. F. Denning. | 10in. refl. |

Allowing for slight errors of observation, the spot follows the old red spot by the same interval as it did on Sept. 26, 1883; hence its rotation period is just about 9h. 55m. 39s. Mr. Miller's estimate as to the size of the new marking on Feb. 2 was evidently excessive, and Mr. Green rather underrates the interval separating it from the old spot; but these little differences are easily explained when we remember that they result from statements merely intended as rough approximations.

It is most desirable to obtain further observations of the new red spot before Jupiter declines so much as to be practically non-observable. I therefore subjoin the times (in hours and tenths) when both the old and new spots will come to the central meridian on the assumption that the latter follows the former 1h. 48m.

| | Old red spot on C.M. | | New red spot on C.M. |
|---|---|---|---|
| May 16 .... | 9·0h. | May 16 .... | 10·8h. |
| 18 .... | 10·6 | 19 .... | 8·3 |
| 21 .... | 8·1 | 21 .... | 9·9 |
| 23 .... | 9·8 | 26 .... | 9·1 |
| 25 .... | 11·4 | 28 .... | 10·7 |
| 28 .... | 8·9 | 31 .... | 8·2 |
| 30 .... | 10·6 | June 2 .... | 9·9 |
| June 2 .... | 8·1 | 7 .... | 9·1 |
| 4 .... | 9·7 | 9 .... | 10·7 |
| 9 .... | 8·9 | 12 .... | 8·2 |
| 11 .... | 10·5 | 14 .... | 9·9 |
| 14 .... | 8·1 | 19 .... | 9·0 |
| 16 .... | 9·7 | 21 .... | 10·6 |
| 21 .... | 8·8 | 24 .... | 8·1 |
| 28 .... | 9·6 | 26 .... | 9·8 |

In the current number of the *Observatory* I have perhaps rather inaptly termed the new marking a black spot, in order to distinguish it from the old red spot, but there can be no question as to the intense red tint so uniformly attributed to the new feature by its recent observers. In comparison with the adjoining belts, it certainly, however, appears very dark.

On March 28 I saw a smaller spot of similar character on the central meridian at 7h. 16m., and following the red spot 5h. 53m.; but I have not looked for this object since.

Bristol, May 8. **W. F. Denning.**

### JUPITER.

[24220.]—MR. BONE (24197) inquires if others saw dark transit of No. III.—on May 2, I presume, although he does not state date. I saw it with 9in. mirror × 275, very dark, at 9 p.m. on that date, about ¼ on disc of planet. It was not well defined, air being bad; but at the same time there was a dark spot on south belt nearly as dark as satellite, and looking much like it in the bad definition that prevailed. This other spot was exactly on central meridian at 9 p. m. No. 3 was not so dark as No. 4 on April 18th. Mr. Denning (24198) saw this as a dark brown spot. To me it was black, as if a round speck of pitch, in same position, and fully as black as shadow of any satellite ever is. May not this difference be due either to bad atmosphere causing the dilution of the blackness, or to bad films on some mirrors. I have often seen statements that the lunar shadows are not so black in reflectors as refractors, but I always put it down either to a badly-figured mirror or a thin film. I am afraid few mirrors have a sufficiently thick film upon them, and flats are worse. At any rate, I can never get a film opaque to sunlight with 50 grains of silver to a 6½in. mirror. It is obvious that any transmitted light will reduce the blackness of shadows, and that a small amount of scattered light, from badly corrected portions of mirror, will so dilute blacks as to make them brown, or, at any rate, short of deep complete blackness.

**Edwin Holmes.**

### DARK TRANSITS OF JUPITER'S SATELLITE III.

[24221.]—As Mr. Bone (letter 24197) asks for confirmation of his observation of a dark transit of Satellite III. on May 2nd, I write to say that it was observed here much as he describes. This is the third time I have observed this phenomenon this year.

Shaftesbury. **T. Perkins.**

[24222.]—THE transit of Satellite III. on Saturday evening was well seen from here, and definition was very good until 11.15, when the air became very unsteady, and Jupiter was getting low down over some houses.

I did not see the ingress at 8.3, but on looking at the planet about 9 o'clock, the satellite was seen as a well-defined, nearly black, spot on the N. equatorial belt, considerably darker than a marking a little preceding it on the S. belt.

I watched it across the disc, and did not see any variation in its shape or lustre until I lost sight of it about 11.30. After egress at 11.43 it appeared as bright as usual.

Powers 250 and 400 on 8½in. With mirror.

Croydon, May 4th. **Alfd. Roods.**

[24223.]—REFERRING to letter 24197, I observed the transit of Satellite III. on April 25th, 7h., when about an hour from egress. It appeared as a black dot, but I could not say if it was quite so dark as the shadow, there being too much daylight in the sky at the time. I looked for it at 7h. 45m., but failed to see it till it appeared as a bright speck close to the limb. I did not notice any dimunition of brightness after egress. May 2nd, at 8h. 22m. saw III. again as a dark dot at 20m. after ingress. As it neared the middle of the planet, it appeared to get gradually darker, and at 9h. 45m., when on the centre of the planet, was nearly black, and just on the S. edge of the great II. belt, Denning's great black spot β preceding it; watched it till 10h. 15m. when it was still a very dark object. Clouds coming on prevented my observing it at egress. On the 18th April observed Satellite IV. just after it had passed on to the planet. It appeared nearly as dark as the shadow of Satellite III., which was on the disc at the same time. I observed it at intervals till egress 11h. 35m., when it was still a nearly black dot. Inst. 3¼ Wray, 120.

Referring to the letter of "A Fellow of the Royal Astronomical Society," I can fully confirm what he says about the difficulty of seeing objects through what (for want of a better word) I term the "solar halo." I picked up Mercury at last eastern elongation, when the planet was just outside the reddish fringe of colour which now surrounds the sun, and of its visibility in daylight I called attention in your journal so far back as 4th Jan., 1884. I also found Venus a few days before superior conjunction, when she was in the "glare" space between the sun and the inner edge of the coloured halo. I have, however, utterly failed to pick up either planet or star in daytime, when their position was behind that of the "solar halo." What is this matter which has so long been suspended in our atmosphere? **T. R. Clapham.**

### ASTRONOMICAL DOUBLE STARS — SELENOGRAPHICAL.

[24224.]—FROM the several observations I have made during the few past months I pick out the following, hoping they will interest some of your astronomical readers, though I can give only estimations of distances and positions; 8½in. mirror:—

Oct. 23, 1884, δ Equulei, P = 230°. Seen elongated so easily that I am inclined to think that the distance has diminished since last year, and that its perihelion is past.

Nov. 8, β Delph. P = 220°, power 600. Air very fine.

δ Equulei, mean of two observations P 232°.

κ Peg., P = 140°. Hardly any elongation with power 600.

64 Peg., P = 80°. Seen elongated at once. β.'s distance in 1880, 592 = 0·34″.

$\gamma^2$ Androm., P = 95°. Very close. Est. dist., 0·50″, perhaps less.

Nov. 9, ζ Sagit., P. = 135°. Powers 600 and 735.

β 658 = B.A.C. 6762, P = 320°. Seems much closer than 0·57″. Notched with power 735.

Nov. 16. β Delph., P = 235°. δ Equulei P = 245°. The star S. of δ Equ. has a distant *comes*, P = 360°.

Nov. 29, δ Equulei, P = 240°.

Dec. 14, β Delph., P = 225°. Well seen with power 180, and with 600 elongation excessively plain before dark. Air good.

δ Equulei P = 230°. Much closer than β Delph. Power 600. Elongation easy with 735, with which I estimated position 225°.

72 Peg. Seen elongated at once with power 200, and comparatively easy with 370. Seems wider than 0·34″ in 1880, 592, β.'s.

85 Peg. After a long gazing and during a calm, I see an elongation towards 310°. Difficult, *comes* about 11th mag.

7 Tauri. Air too unsteady for any power above 200, with this just seen elongation towards 235°.

January 19, 1885. 32 Orionis. Well elongated. P = 165°.

March 2. 126 Tauri, P = 240°.

March 5. 126 Tauri, P = 240°. Power 200. Just seen elongated. Very probably the movement is retrograde.

Σ. 3121. I found elongation towards 250°; but this is doubtless wrong, as β gives 185° for 1878·2, and 199·8° for 1880·315. Are there any later measures?

ω Leonis, P. = 100°. This star has moved, as β. gave 79·8° for its position in 1879·78.

O.Σ. 234. I thought I could just glimpse a slight elongation in direction 150° — 320°, which is the position β. gives in 1878; but in 1880 he gives 170° D. = 0·18″, and calls it excessively difficult with the 18½in. refractor.

Referring to letter 24199, I think Mr. Ed. Holmes must be wrong in the position angles he gives of γ Leonis and 54 Leonis. Last night I estimated the first at 125° ± and the second at 130° ±. I also found ζ Boötis at 295°; 42 Comæ Berenicis at 130°, and 25 Canum Venaticorum at 175°. This last seems far too close as a dividing test for a 6½in. Perry found 0·31″ distance in 1882·36.

May I direct the attention of your selenographical readers to the eastern portion of the Alps, where I have found several new clefts lately? They were just within the limit of visibility of my instrument, and very evanescent. I could not take the positions of all those I saw; but so far as I could sketch them, they will be given in my map of the Moon, soon ready for the printer.

**C. M. Gaudibert.**

### STAR DISCS AND VISIBLE ANGLES — ROYAL ENGINEERS — POWER OF OPERA GLASSES — THE SPECIAL MEETING OF THE ROYAL ASTRONOMICAL SOCIETY.

[24225.]—I THINK Mr. Edward M. Nelson's difficulty (letter 24201, p. 212) has chiefly arisen from his not considering the false discs which are raised on stars viewed by a telescope. The distances separating double stars are really the angular distances between the *centres* of these false discs; and as the discs increase in size as the aperture of the telescope diminishes, it is quite evident that the actual width of dark space separating the components of a telescopic double star varies with the aperture of the telescope used, as well as with the power. Moreover, in the case of stars, such as Polaris, where the primary is bright and the *comes* faint, one can scarcely expect to see the latter when only just separated from the dazzle of its primary.

I would propose an experiment to Mr. Nelson. Let him get hold of a small telescope about 1in. aperture. Now make himself a very low power for his 4in. (I have made lots of low powers out of old microscope tubes and lenses; they are very easy to make, as achromatism doesn't matter much with low powers), and try with what power he can just divide a star whose components are about equal in magnitude—Castor for choice. Now use the equivalent of this power in his 3in. and the discs will be in contact, and with an equivalent power in the 1in. there will scarcely be elongation of the star, although its components are still separated by the same angle. In fact, the larger the telescope the lower the power required to separate a star from its *comites*, within certain limits. As to the theoretical angle which is just visible, that depends entirely on the eyesight of the observer, and the conditions of illumination. It requires very unusual eyesight to separate $\varepsilon^1$ or $\varepsilon^2$ Lyræ by the naked eye; but I think that is as much caused by their faintness as their distance; and the state of the atmosphere and the altitude of the star have much to say to their divisibility. If Mr. Nelson would grant me my own conditions of illumination, I would undertake to show him a far smaller angle than 207″. I have seen sunspots with the naked eye, which did not subtend so large an angle.

I do not think the formulæ, which he speaks of in the last paragraphs of his letter, would be of any practical use, as the size of the star discs vary more or less with the state of the atmosphere. No doubt they could be worked out theoretically by the same means as the limit of dividing power of a given aperture is found.

In answer to "F. L. B., Kew" (query 56508), his best plan would probably be to enlist in the Royal Engineers as a telegrapher. He must be 33½in. or upwards round the chest, and not above 25 years of age. If accepted, he will be sent to the Postal Telegraph Companies at Bristol and thoroughly tested and given a certificate. He is then enlisted if approved of. If he is not versed in practical telegraphy he can enter as a sapper, by special authority. The pay begins at 1s. 1½d. per diem; but "F. L. B." would no doubt obtain rapid promotion, and eventually reach the rank of Sergeant-major, drawing 6s. a day as a warrant officer. He might get a commission as quartermaster, or even as a lieutenant, but not in the R. E. itself, as both it and the R. A. are entirely officered by men who have been through the Royal Military Academy.

As to the work, "F. L. B." would be pretty sure to be employed at that which he was found best able to do, which would also no doubt be what he liked best. And if really well educated, he would have a good chance of snug appointments, with good pay, in the R. E.

If he requires further information, I would recommend him to go to the deputy adjutant-general, R.E.'s Office, Horse Guards, and inquire for Sergeant Tucker, R.E., who will give him full information and be glad to enlist him if eligible.

(Query 56534. Opera Glasses.) Let "Devoniensis" rule off a scale of equidistant black lines on a sheet of white paper, pin it on the wall, look at it with his right eye direct, and with his left through one tube of the opera glass, and by moving the latter make the two images coincide. Suppose the glass magnifies four times, then the magnified distance between any pair of lines will be wide enough to hold four of the spaces seen by the naked eye, and so on. It is very easy to do. There are other methods theoretically exact, but that is the simple practical one.

I should like to inform "F.R.A.S." that I was personally most anxious to attend the special meeting of the Royal Astronomical Society and vote with him and his; but, owing to the work that the Russian trouble has imposed upon us army men, I found it impossible to go. The motion had my best wishes, I need not say.

**Garrison Gunner.**

### ζ HERCULIS—γ AND 54 LEONIS, AND COR CAROLI.

[24226.]—THE distance of ζ Herculis (about which "Beta" inquires in letter 24165, page 187) is now about 1·60″, and the position angle about 89·0°. The companion will remain at about its present distance until 1891—1892, when it will again begin to approach its primary. The following are some of the measures of this interesting binary since 1876:—

| | | | | |
|---|---|---|---|---|
| De. | 139·60° | 1·366″ | $7^n$ | 1876·56 |
| " | 133·85 | 1·357 | $8^n$ | 1877·53 |
| " | 126·66 | 1·381 | $7^n$ | 1878·58 |
| Hall | 120·75 | 1·498 | $4^n$ | 1879·46 |
| β | 114·12 | 1·368 | $5^n$ | 1880·49 |
| " | 110 60 | 1·532 | $5^n$ | 1881·45 |
| Sch. | 101·55 | 1·473 | $11^n$ | 1882·60 |
| Pe. | 99·50 | 1·495 | $4^n$ | 1883·52 |

In 1882 Mr. Simms found it clearly separated with 3¼in. aperture on his 4in. Cooke, power 225. The distance of the *comes* of δ Cygni is about one-tenth of a second of arc greater than that of ζ Herculis at the present time; but the magnitude of the companion of δ Cygni is somewhat less than that of ξ Herculis. The position angles measured by Mr. Holmes (letter 24199, page 212) are all too small, possibly owing to the stars having been measured off the meridian (?) with a reflector. For γ Leonis Küstner found 114·26° : 3 46″ : 1883·36, as the mean of seven nights' measures with the 10·1in. Merz at Hamburg; the angle should now be about 115·5°. Hall gave 107·20°; 6·41″ for 54 Leonis in 1879·24; in the case of this pair the increase in angle is very slow, the distance remaining unaltered. ♅ found 99·2° : 6·41″ : 1781·63. The measure in Webb is Smyth's, epoch 1839·33. Cor Caroli has remained unchanged during the last 100 years, although a common proper motion has carried both stars through 25″ since the first measures of ♅.

**H. Sadler.**

---

## SMALL REFRACTORS AND TESTS.—ERRATUM.

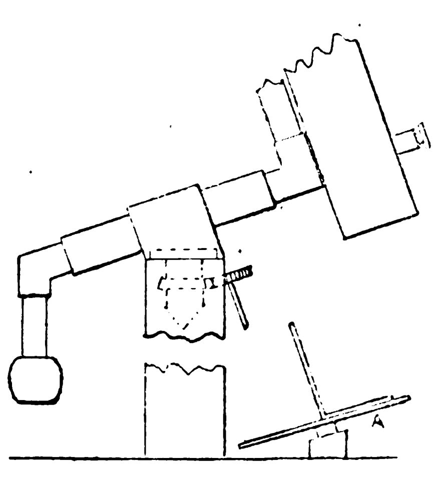
[24227.]—For "*a* Lyræ, power 46½, aperture reduced to 2in. (*comes* held steadily)," read *a* Lyræ, power 46½, aperture reduced to 2¼in. (*comes* held steadily).

**Edward M. Nelson.**

---

## CHEAP TELESCOPE STANDS.

[24228.]—I read with interest Mr. Vallance's description (May 2) of his method of mounting his telescopes. "Montmartre" in the next letter suggests a plan by which this ingenious method could be combined with an equatorial movement. His plan (that of a stepped floor) seems to me, however, to be unnecessarily cumbrous; and I send sketch of a much simpler one, which suggests itself to me.



The sketch explains itself to those who have read Mr. Vallance's letter. The pulley arrangement is left out for simplicity. A is a graduated circle, the index hand of which is connected with the axis of the movement. A driving clock can easily be applied.

**H. Ritchie.**

---

## THE DOUBLE TELESCOPE.

[24229.]—The scheme proposed by "Montmartre," in your issue for May 1, 1885, p. 189, No. 24171, of using a pair of 10in. or 12in. mirrors, with two pairs of flats, for bringing the axis of vision within range of the two eyes of one observer, would involve the distortion of the resulting image to a very surprising extent to any one who has not had any analogous experience.

The effect of separating the two points of view for binocular vision to an extent exceeding the natural distance between the centres of the observer's eyes, can be easily studied by taking pairs of photostereographs and viewing them in the ordinary stereoscope.

In general terms, the resultant effect is to materially dwarf the mental image perceived, so that the observer fancies he is regarding a small model of the subject under examination; but incidentally there is also introduced a curious distortion by exaggeration of the apparent distances of the objects, or part of an object situated at different distances from the eyes. Owing to excessive displacement of the objects in the foreground, as compared with those in the distance, the latter look as if they were much further and relatively larger than they should be; and as one of our contributors, when discussing this question with the writer, in the early days of the telescope, aptly remarked: one could easily arrange a stereoscopic portrait so as to make a man's face present the appearance of a hatchet or a pickaxe, and stretch his nose to a yard in length.

Without asserting that I have actually made the nose appear exactly a yard in length, I have tried the experiment, and brought it (the nose) to look very like the point of a pickaxe, and to be a good proportion apparently of the said yard in length.

**Gamma Sigma.**

---

## EVOLUTION.

[24230.]—"Pre-Adamite's" difficulties with regard to evolution (letter 24202, page 212) are typical. Like many others, he appears to have read enough to know that the doctrine is now generally accepted by those who are in a position to appreciate the evidence for it—those whose professional studies make them acquainted with the details of comparative anatomy and its kindred sciences, or those who unprofessionally have considered the subject of sufficient importance to make them undertake the study of the evidence for themselves. People like "Pre-Adamite" either cannot or will not undertake this study, but expect to have every difficulty that occurs to them cleared up in a few sentences; and the task of those who attempt to enlighten such people is not made easier by the fact that first of all the misconceptions as to what evolutionists believe and teach have to be corrected. Seals and whales are not regarded as links between fishes and mammals, as "Pre-Adamite" supposes. Seals and whales are mammals which have become adapted to an aquatic mode of life, and there is plenty of evidence to show that they have descended from four-footed land mammals. The whalebone whale, for example, has no hind limbs, but it has a rudimentary pelvis (representing the bony girdle to which the hind limbs are attached in quadrupeds), and there is also a rudimentary femur or thigh-bone, and a cartilaginous tibia, representing the leg bone. The same animal has no teeth, but the unborn young animal possesses teeth which, however, are absorbed, and never cut the gum. As some one has suggested, these rudimentary organs may have been created for the purpose of misleading men of science, and of making them believe in evolution, to their confusion. On the creation hypothesis, we know, all things are possible; but, on the whole, it seems more reasonable to believe that rudimentary structures are remnants of structures which were useful to the animal's ancestor. There are many structures possessed by animals which might, perhaps, as well be explained by design as by the theory of descent with modification. Useless rudimentary organs cannot, however be explained by design, but can be very reasonably explained on the supposition that the conditions or surroundings of an animal's life having changed, certain organs are no longer useful, and therefore tend to become aborted. On the principle of heredity both useful and useless organs are reproduced, but the former are developed by use, the latter tend to abort from disuse.

"Pre-Adamite" wants to know what reason there is "to suppose that a fossil creature, half-bird and half-lizard, or other recognised intermediate link, is so in reality?" The evidence for this depends on the comparison of the structure of allied forms living and extinct. As I have no doubt others will supply "Pre-Adamite" with information on this point, I will not attempt to do so at present; but should no one else write on the subject, I will undertake, with the Editor's permission, to give the evidence in another letter.

In conclusion, I think "Pre-Adamite" should not find it difficult to imagine such a change in the environment of a parrot as should necessitate the disuse of its beak for climbing. Let him suppose the district inhabited by the parrot to become destitute of trees, and I think his difficulty on this point will be at an end. Geology affords evidence of changes in the surroundings of animals, which must have produced effects on their habits quite as remarkable as would the one I have suggested.

**Rex.**

---

[24231.]—"Pre-Adamite" has, I am afraid, rather confused ideas on the subject of evolution. If a lizard is quite a distinct creature from a bird, and there exists another creature which is half lizard and half bird, that other creature is evidently half-way between the two, and may, therefore, be called a "link" (there may be some other creatures which are three-quarters one and one-quarter the other).

"Pre-Adamite" says: "Suppose the seal to die out of existence, it would, I presume, be called a link between mammal and fish." The fact of its "dying out of existence" would have nothing to do with it (besides that, we have fossil mammals far back in geology). Evolution says fish were the ancestors of mammals; and creatures half fish and half mammal are, therefore, the descendants of creatures which were descended from fish, but are not necessarily like those creatures. Speaking of the bird with teeth, "Pre-Adamite" says, "I see no reason why the creature should not have been so made." What *does* this mean? Of course it was "so made." The question is "How?" Evolution says by a gradual development from creatures similar, and not from nothing. The theory of special creation teaches that the ancestors of a creature were all very nearly like it and each other. This leads us back to inquire where the first came from; and in that the one theory, that of evolution, is far more explicable than the other; it is the one accepted by the mind (the will has nothing to do with it) which grasps most firmly that which it can most readily understand.

Again "Pre-Adamite" asks why a creature should cease to use a limb. He seems to have the idea that the disuse of the limb is begun by one creature, and that none of its descendants ever use it. This is as far from the case as possible. The cause of disuse is external to the animal *always*. But there are so many causes that it is useless to try and explain, except, perhaps, by an example. Take the case of the parrot, spoken of by "P." at the end of his letter. Suppose that in a thickly-wooded country there is a race of parrots which have strong beaks, which they use to a great extent in climbing, and suppose that, for some reason, part of the race is driven out of the country (the cause may be various, such as a change in vegetation, the aggression of hostile animals, the increase of the tribe itself, &c.), and, not finding another so woody, settles down in a thinly-wooded district; the tendency to climb is less, and that to fly and walk greater; the strength of the beak is of little use, not being required to find food. Birds with weak bills have as much chance, in the struggle for existence, as those with strong, while wings and other limbs (being more required now), being stronger in some of the birds, give them a better chance, and they become healthier, increase more rapidly, and in some generations' time, parrots with powerful wings and beaks of little greater strength than those of other birds, will have descended from a race with comparatively weak wings and beaks strong enough to enable the bird to use it to climb with (and which may still be in existence).

Now, why not add many such changes together? It is far more likely that there is a continual change of this sort than that there is none at all (in the country there certainly is the change which has always been going on on the earth's crust, and which is the indisputable, except to those who know nothing about it, evidence of geology); but the geological change is far more slow than the one I have supposed, and is, therefore, far more powerful.

There is no living thing which is so totally different from all others that all life cannot be formed into a rough chain from the lowest to the highest forms; but it must be borne in mind that the highest living form has not been evolved from the lowest living form *now* in existence, but both from something else, and this is one great reason why the chain of *living* forms is not perfect.

## MYSTERY GOLD.

[24232.]—The following paragraph will explain what is meant by "mystery gold," referred to by "Sigma" on p. 193:—

"An alloy containing enough platinum to enable it to resist the action of nitric acid is now being extensively used as a means of defrauding buyers of trinkets, and Mr. W. F. Lowe, who has analysed the alloy in question, gives, in the *Chemical News*, the following particulars. The alloy, after the gilding had been scraped off, had about the colour of 9-carat gold. Qualitative analysis proved it to consist of platinum, copper, and a little silver; and quantitatively it yielded the following results:—

| | |
|---|---|
| Silver | 2·48 |
| Platinum | 32 02 |
| Copper (by difference) | 65·50 |
| | 100·00 |

Strong boiling nitric acid had, apparently, no action on it, even when left in the acid for some time."

When thickly-plated this alloy is said to pass muster for gold of high quality, and many pawnbrokers and others are said to have been deceived by it. Considering the difficulty of alloying the platinum and the cost of the latter, it can only be by gilding that a sufficient profit can be obtained; but perhaps some of your readers can give the relative value as compared with 9-carat gold—which is worth £1 11s. 10½d. per ounce. Alloys of silver, copper, and platinum have long been employed on a small scale in jewellery and watchmaking; but is there any proof that they have been successfully used in the production of imitation sovereigns?

---

## CHEAP SET OF RESISTANCE COILS.

[24233.]—Will you kindly allow me to point out to my fellow readers of the "E.M." that the Wheatsone bridge described by Mr. Bottone last week has been on show at Kensington Museum, in Prof. Guthrie's set, for *some years*, and forms part of the cheap set of apparatus manufactured by J. J. Griffin and Sons for the Science and Art Department?

**J. Edgington.**

95, Vauxhall Bridge-road, S.W., May 11.

---

## SUBDIVISION OF THE OHM.

[24234.]—After the letter of our able correspondent, Mr. Bottone (24212), "How to put up a set of Resistance Coils," it occurred to me that some of our amateur electricians, who are constructing small dynamos, would like to subdivide the ohm, enabling them to measure low resistances.

Measure one ohm of German silver, No. 16

B. W. G., with a Wheatstone bridge, carefully divide into ten equal parts, and at each division a copper wire is soldered, which enables tenths of an ohm to be used. For hundredths, a brass wire one-tenth of an ohm of No. 18 gauge may be taken and treated in the same way; No. 10 brass wire for the thousandths of an ohm.

The bridge described by Mr. Bottone is quite suitable for this purpose, except when measuring the hundredths and thousandths, it would be advisable to insert between the two spaces of the long and short strips of copper coils of equal resistance with the standard and wire to be measured. Trusting that the above may be of general interest.

West Dulwich. **W. Habgood.**

## THICKNESS OF COPPER PLATE FOR MODEL BOILERS.

[24235.]—In some experiments on the strength of brazed copper tubes, it was found that they rapidly lost strength with the lapse of time.

Pipes which, when new, burst with 10,000lb. stress gave way, after three years' use under steam, with less than 5,000lb. stress per square inch.

In no case did the joint give way. Taking 5,000lb. as breaking stress, and allowing a factor of safety of 5 the working stress will be 1,000lb.

Assuming 20lb. per square inch as a fair working pressure for model boilers, we get the rule—Thickness = ·01 D, when D = diameter in inches.

It is not easy to make a good joint if the plate is very thin, so we will say that the plate is never to be less than 20 B.W.G., or ·035in. thick.

By plotting these results in a diagram, the following rule is arrived at for brazed cylindrical copper boilers with a working pressure of 20lb. per square inch above the atmosphere.

Thickness in inches = $\cdot 035 + [\,(D - 3\tfrac{1}{2}) \times \cdot 01]$.

Thus, a boiler 6½in. diameter would be $\cdot 035 + [(6\tfrac{1}{2} - 3\tfrac{1}{2}) \times \cdot 01] = \cdot 035 + \cdot 03. = \cdot 065$ or 16 B.W.G. thick. **Glatton.**

## NEW MIDLAND ENGINES.

[24236.]—Your correspondent "Midland" commences his letter, p. 217, by expressing some very decided opinions against the new Midland engines, and goes on to say that the fault is "shortness of heating surface." He then concludes by asking if no one will come forward "and do battle for them"; and appears astonished that, as I some years ago defended the 800 engines, I have not entered into the present discussion upon the 1667 class.

Every word that has been said in praise of the 800 design of Midland engines is, I believe, perfectly true and well merited. I defended these engines in your columns some years ago, and should feel perfectly justified, by facts, in doing so again if necessary. Unfortunately, I am not able to say as much for the new 1667 design; for this reason, as "Midland" says, I have not entered into the discussion.

Your correspondent, in the last line of his letter, refers to large "cylinders" and "Joy's gear," as if under the impression that these were in fault; other correspondents have implied that the drivers were to blame.

I can, therefore, state that the 19in. cylinders are right, the Joy gear is perfectly true and correct, and that no fault whatever rests upon the drivers, who are experienced men.

I am extremely glad to see that within the past week or so the big engines have been doing rather better, and doubtless, if they had had larger boilers with about 300ft. or 400ft. more heating surface, they would have been very grand engines, and numerous correspondents would have been conscientiously able to accept the challenge to "come forth and do battle for them"; but in view of facts, as they are at present, I fail to see how they can be expected to do so.

**Clement E. Stretton, C.E.,**
**Hon. Mem. A.S.R.S.**

## BRAKE POWER ON THE NORTH-EASTERN RAILWAY.

[24237.]—Will any of our North-Eastern friends tell us what brakes are in use on that line? Are those through trains from King's Cross to Glasgow worked over the North-Eastern with the *air* brake or the vacuum? I see some of the engines fitted with two brakes and the carriages as well; I suppose they don't employ both at once; if not, which do they use. Now this line has all its carriages with the air brake. I don't just see what use those 13 engines are with the vacuum only. What trains can they work? Perhaps "Meteor" or Mr. W. J. Grey could throw light on the matter.

I may just remark the quantity of carriages on English lines which have *two* brakes, it would be interesting to have a table showing the amount of *double fittings*. I expect it is the only way to arrange for exchange of carriage, but it is an expensive one, in place of one brake for the whole land; do not your readers think so? At Stratford, I see a number of Great Eastern engines and carriages having the vacuum brake taken off; how is this? What brakes are now in use on that line?

**Anxious to Know.**

## CRANK AXLES.

[24238.]—It seems that these crank axles break through the webs, and it also appears that the iron is the wrong way of the fibre. Now would it be possible to forge a crank so that the fibres all run in the right direction? Could not the iron be built up and then welded into one mass?

If, as we have been told, the chief cause of breakage is the pinching action of the rails, it seems to me we require more elasticity in either the wheels, the axles, or the rails. Could not there be a system of rail key to give a little amount of elasticity to the side play. I see in "Scientific News," p. 210, last week, that the Railway Servants Society consider that axles should be taken out when they have run a certain mileage. This is a very good idea indeed. **Locomotive.**

## INTERCHANGEABLE MANDRELS.

[24239.]—We have now got rid of the suggestions as to coning the chuck-bearing surfaces of the mandrel-head, and a few more letters should wind up the discussion, if we take up one point after another.

"Tubal-Kain" (24206), page 215, gives us a careful drawing of a mandrel-head, with some good points. But the nose is too long. So long a nose does not assist in eliminating "angular variation," inasmuch as that is got rid of by the wide face, and as I have said at page 104, the eccentric variation is efficiently got rid of by a concentric cylinder-fitting, as thick as a florin. If the angularity of "Tubal-Kain's" thread, or its cylindrical top or bottom, can be made to centre the chuck, show us how this can be done so as to meet the requirements which Dr. Edmunds has pointed out. I think that "Vulcan," "F. A. M.," and the "Doctor," are perfectly right in saying that no screw can be made a sound practical means of concentric fitting. In all the fine compound chucks used in ornamental turning he always fits concentric work together by means of combined cylinder and face fittings, and there is no screw fitting which could be made to maintain the necessary truth. The transfer chucks used in ornamental turning act upon these principles, and could not otherwise be made to answer. These transfer chucks were carefully examined, and fully explained by Dr. Edmunds in some papers written by him for the ENGLISH MECHANIC (July and August, 1884). In these papers the transfer chucks used by Mr. Henry Perigal and General Clarke for their beautiful geometric works were figured and fully described. If "Tubal-Kain" will refer back to ENGLISH MECHANIC No. 1009, page 453, and study that paper and others which follow it from Dr. Edmunds's pen, he will see that while a screw-nose may, with very excellent workmanship and extreme care in using, be made interchangeable, the construction is not sound workshop practice. The very mandrel-head now figured by "Tubal-Kain" depends for its truth upon the long screw-nose, and if that got damaged by some accidental knock the mandrel would be ruined. No doubt the screw-nose might be "judiciously touched up again in a strong screw-cutting lathe by an efficient workman," and would again run true; but then all the ornamental chucks would be too large, and would be useless. At page 189, Dr. Edmunds, referring to "J. K. P.'s" proposed screw centring, among other questions, asks: "Why is it that in accurate tool-making the old screw fittings for shifting head-stock and mandrel back-centre have been superseded by cylinder fittings?" Perhaps those who still advocate screw fittings will answer these questions before going on to write more.

I find that my own lathe centres are turned up to a cone containing 6°, and for 15 years I have kept to this 6° taper as my standard. Our own lathes get a full thwack of hard labour, and this taper for the centres is satisfactory; I have never known one injured when made to this taper. This is turned up by simply setting the slide-rest to 3° on the quadrant. A more acute taper would, I think, frequently get set fast in both mandrel and poppet cylinders, either of which would be liable to get forced open or enlarged to a perceptible extent. The small drills which I make to contain 3° hold so tight as not to need any set screw, although we put a set screw into the spindle when made to carry side or bent cutters, or an eccentric cutting frame.

My measurements also make the American cones for chucks and twist drills to contain 3° only. I was unaware previously of this coincidence, but the fact shows that the standard taper of 3° for a long cone of this kind is reliable, and I think that the taper of twice the above—*i.e.*, to contain 6°, is also reliable for exchangeable lathe centres. Lathe centres have to bear heavy end pressure, and they must come out readily. In the Edmunds model mandrel they may, of course, be knocked out from behind, and there would be less risk of injuring the cone inside the mandrel-nose, but if because of the advantages of the tubular arrangement a more acute cone was used, there would still be the risk of enlarging the mandrel-nose unless it was made still larger in diameter; in fact, since writing previously upon the interchangeable mandrel, and taking into consideration the value of the eight pitch 50° angle screw nose, which I then mentioned as having been brought to my notice by Dr. Edmunds, I have constructed a mandrel which I consider embodies the Doctor's views on the subject. I will shortly send a clear outline sketch, full size, which I trust will convey to our readers a thorough knowledge of what Dr. Edmunds has endeavoured to bring to perfection in the interests of amateur turners throughout the world.

Griffin Works, Norwich. **Edward Hines.**

## CUTTING SCREW-THREADS WITH A REVOLVING CUTTER.

[24240.]—I should like to say a few words upon this much-debated subject, if our worthy Editor is not tired of the controversy. There seems to me to be too much confounding square threads with V-threads. Now, I believe no one asserts that a square thread can be cut or finished with a revolving wheel or cutter, but the case is entirely different with V-threads, and this I purpose showing in a few plain words.

Taking a square thread first, let us take a revolving wheel-cutter with face and sides exactly to match the groove of thread, set it accurately to the rake of thread; but before putting it into actual cut let us consider the points at which it will do so. Now, our wheel possesses two flat and one cylindrical surfaces, and its points of contact with the work will be two surfaces and one line, as everyone must know that two cylinders, or two cones with their axes in the same plane, can only touch upon a line, this line being also in the same plane; but the two surfaces forming the sides of a square thread are not flat, but curved (in fact, a helix), and a moment's consideration will show that by no possibility can our wheel fit the screw groove before us. If it be put into cut, the resultant thread will not be a square thread, but will be narrower at the top than at the base, and with hollow sides, more or less, depending upon the size of the wheel and rake of the thread. The bottom of the thread groove would also be slightly hollow; but if the cutter be correctly placed, the thread will be upright upon its base and true in other respects.

Now, when we come to V-threads the case is entirely different; here the cutter acts upon two lines only, meeting each other at the bottom of the groove (for here we have four cones touching in pairs), and as soon as each point in the surface of those cones has come into contact, the convexity of their surfaces immediately carries it out of the way, and the groove cut by such a V-cutter will be an exact counterpart of that cutter; if with 50° angle of cutting faces, the groove cut will be exactly 50°, neither more nor less, "providing it be measured at right angles to the rake of the threads not parallel to the axis of the screw blank." This I do not doubt has misled several of our correspondents, for if we wish to cut a thread of 50° measured parallel to the lathe centres, we must have a revolving cutter of slightly more than 50° This will depend entirely upon the pitch of the thread, and to do so we must have a separate cutter for every different pitch; but if we measure at right angles to that pitch, the same wheel or rotary-cutter will answer equally well for any pitch, and be in each case strictly accurate.

**Hadah.**

## CUTTING SCREW THREADS—LATHE MATTERS, &c.

[24241.]—I have gone carefully through the recent correspondence, including the Dr.'s last. I have not relied solely on "my mind's eye" for my statement; in fact, Dr. Edmund's will find that organ not too reliable in mechanical matters, though the questions before us are of course mainly theoretical and in statics, and therefore, by the general rule, for the most part competent to be dealt with deductively.

A lawyer would say there was no error in all or any of my letters. Strictly speaking, there is not; though on writing my first note on Mr. Wenham's *fiat*, I had not paid any great attention to Dr. Edmunds's thread in particular, nor exactly understood its more minute or claimed properties.

On page 60 I wrote, "if a *thread* were cut," whereas the question was of a *groove* in ordinary language. It was read over several times before being called a misstatement, which to the general reader it would no doubt appear. The note itself just escaped being recalled.

I like the 50° thread very well; but I am not just at present prepared to give an opinion on the *best* methods of dealing with a nose. If a nose is hard, the hardening should grow lighter towards the shoulder, and not exist for about one turn in advance of centring: otherwise the nose will lack holdfast strength. The sum of the stresses on all the threads is borne by the cylinder area at junction with centring, growing lighter to 0 at outer end of nose.

On a soft nose, taking alone the results obtained by "J. K. P.," there does not seem much fault to be found with fixed edge tools. For a hard nose, a revolving Tanite or other emery grinder seems a likely tool for trueing; but perhaps for the best work Dr. E.'s own process will turn out the best.

There is not much analogy between a square and a V-thread cut by discs. In the former case the question is of surfaces, in the latter of lines; and in this case, also, of lines that can be made easily to any desired form by legitimate processes.

But the case of the cedar pencil, as was also that of the "skew-gear," was correct; and an inclined cutter, normal or abnormal, must be accurately on "lines of centres," as it is generally termed. It reads strangely in par. 7 (24172), the argument against the need of this aligning, as in par. 11 it is pretty clearly explained why it should be on line of centres—i.e., on account of longitudinal component.

Once set in its bearings and frame to proper position—this is not difficult to do, and the angle, instead of adding to trouble, offers a delicate means of adjustment by traversing spindle in its bearings—it is always there, and there is not trouble as with grinding V-points.

A cutter in a frame with a divided head that could set it to various rakes, would cut abnormal non-reversible threads *ad lib.*; but the degrees of departure from the normal would vary with the angles—the more upright, the less. I send a diagram of such a cutter set for a quick screw, but at a maximum off centre—below screw. The angular set goes entirely to deform the thread, and its original purpose is gone, as the cutter has no inclination left to the pitch of the thread, but is at right angles to axis of screw in plan.

Cutters made for one angular inclination (all ways) of a thread, and having their edges or contacts on an axial line as to screw, would only as strict practice be used for such angles; if used, as they might be for slightly more or less angular pitch on reduced diams., such as they would clear, they would still have to keep their position as fixed, or they would produce abnormal threads, their action then being off the axial line. If of small diam. themselves, they would clear slight variations of pitch in larger or the same diams.; but strictly, they would only do for one number of threads on a given diam., and that, I take it, is what "J. K. P." means. On different diams. they would cut accurately any number of threads that required the same angular set: 10 per inch, 20 per ½in., and so on, as in a decimal system.

For a uniform degree of abnormal nature, the inclined-acting cutter or lap would also have to maintain its original angle.

I have gone over par. 8 several times, and am not satisfied on it yet. There is nothing more misleading than to begin reasoning from a plane to a cylinder in screw threads. The reason is this: that when the question of traverse enters the thread, a cutter that cuts grooves of the axial section of the screw thread on a flat will not fit any section whatever on a true cyl. screw; neither the normal nor the axial section, as it cuts *normally* on the flat, or *obliquely* to what becomes the axial section when the plate is wound round a cylinder, and the normal section on a cyl. is bent away and curved in winding the plate round it; the section that becomes axial is of course wider at base than the original cutter working on the flat. To produce the proper groove on both cylinder and flat, the cutter must act on its edges obliquely to its rotation axis, and in the plane of the supposed screw axis.

To proceed as in par. 9 would result in satisfaction and some interesting models for exhibition.

In par. 10 the thread is said to increase in angle as it approaches the axis till it coincides with it, becoming a straight line. A ship's propeller is about the best illustration of this.

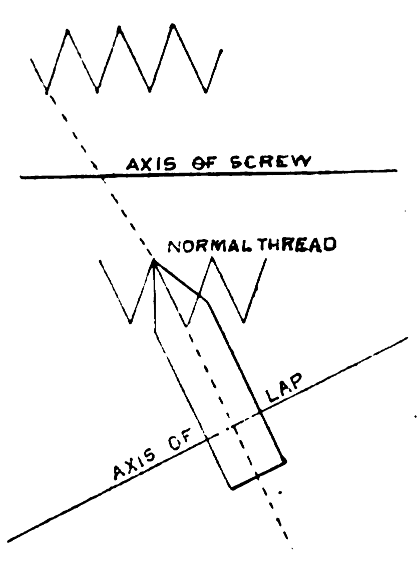
That Mr. Wenham was right so far as saying that an already true thread—i.e., a symmetrical one—would be deformed by a lap of its axial section set angularly and to work upon it, is and has been quite evident; but I should like to say a word on his challenge. He appears to forget, in the first place, his remarks on "self-constituted authorities," and the benefit accruing to any one answering the gage is not conspicuously evident. The trouble and expense involved seem definite enough, as the challenge is carefully worded to include both revolving cutter and grinder as well as the screw.

Nevertheless, a little hunting-up would probably unearth the articles, and in the ordinary way of business it seems very likely that they will at any rate be shortly forthcoming. The quotation of "J. K. P." reads falsely or without meaning. A cutter or grinder made and set to a decimal or other system would do for many numbers per inch on different diams.; in fact, they would work throughout up to the full depth of their cut on systematised screws—ten or other number of turns in their own diams. always needing the same angles.

"J. K. P." is only right as to number of threads on one diam. of screw, and that is not what his sentence, as quoted, implies by any means clearly. The note of mine to which "J. K. P." refers was promiscuous, and only partly for himself.

The writer whose advice heads our columns ended his page with "Que scais-je?" Rather a startling difference between it and the "impressive" announcement. Hence some of my "sarcasm," so called.

My ideas on the cylindered mandrel are clear and decided, and I believe in it. The screw nose must, of course, be true and well finished, hard outwardly; but I am "not going to bother myself" getting up such a *large, complex, worked upon and exposed*, surface to such pitch as I think a centring should be finished to, as I know it would not endure if I did, and that I should be mechanically foolish to attempt it when I know that a *small, simple cylinder, well-protected*, and comparatively quite *free from travel and stress*, is all that is needed.



As for the talk about de-centred noses, it is simply holding up to ridicule, by experience apparently, the degenerate state of general workmanship, and is a re-echo of the "foreign competition" note just restruck alongside.

Returning to stereometry and the normal section, the principal points that strike me in connection therewith, from my own points of view, are that in reversible threads—*i.e.*, threads in which the axial section is bisected throughout by a radius cutting its apex on the centre of its summit—the only tool that can work on the normal line is an edge formed by hacking off a nut-thread that has been cut on top to normal lines, and was made on a list of the exact size of the finished screw. The customary chaser is cut by a hob of larger diameter than the screws cut to give clearance; but their edge is in an axial plane, and they have a false section if edged out of that plane.

Nor yet again can any revolving, inclined tool work upon the normal section truly, as the axial section projects beyond it, and would be cut away thereby. If such a disc is attempted to be fitted to a normal line on a symmetrical screw, it will be found to be only possible to fit it to the axial section; when working, it will, of course, produce a true normal section. An upright parallel disc of sufficiently small diameter to clear might be cut to operate on the normal section of a V-thread; but I would rather be excused from either attempting to make one accurately, or even to define the nature of its curves.

In par. 9 is not "stereotomy" a misprint for stereometry?

What we are writing about seems to me to be something of a "worm that dieth not." Several correspondents have settled it, or scotched it, in their several letters, yet it flourishes apace. I fancy the general reader will now have about lost sight of its two extremities, and will relegate it to the transcendental mathematics, politely speaking.

Vulcan.

---

## THE PRODUCTION OF SCREW-THREADS.

[24242.]—I THINK Dr. Edmunds and Mr. Hines are mistaken in the view they take of one branch of this subject—viz., the trueing up of V-threads by means of revolving lap-wheels. The theory as expounded by the former gentleman (24172) is that, "by the use of a revolving V-cutter, or V-grinding wheel, traversed by means of change-wheel arrangements, and having its axis tilted for the pitch of the thread, the most perfect thread possible can be trued up with ease and certainty" (some may be inclined to doubt the utility of "trueing up" a thread, which is already as perfect as possible).

Fig. 1 represents a double V-threaded screw; a section of the thread made by a plane passing through the axis of the screw, being represented by Fig. 2. Here I may say that in taking this form of thread I have been guided only by convenience. A E B will then represent the position of the revolving lap-wheel, being at the angle which the top of the thread makes with the vertical. C E D, at right angles to A E B, is then the axis of the lap-wheel, the point E being in the same horizontal plane as the lathe centres. Then a section of the thread taken along line C E D, and in such a direction that point E passes through the axis of the screw (that is horizontally), is as shown at Fig. 3. Therefore a lap-wheel with a V edge, the sides of the V being straight, would grind the sides of the thread hollow, the error being smaller the smaller the pitch and the larger the diameter of the screw, but always existing.

FIG. 2.

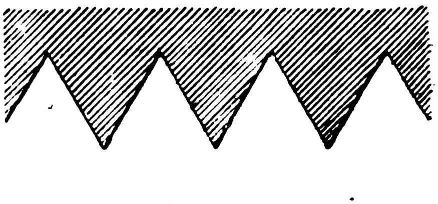


FIG. 1.

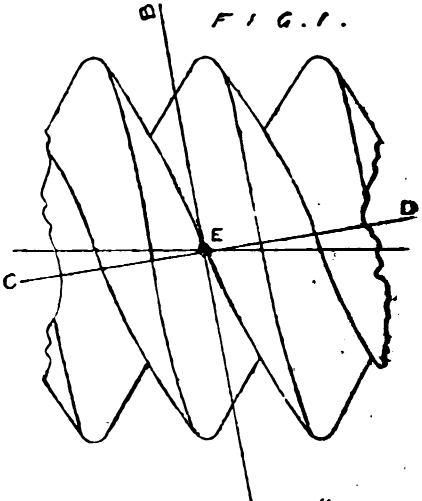

FIG. 3.

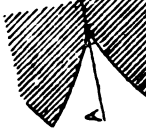

It may be asked: Why not make the sides of the lap hollow? But leaving out of account the difficulty of determining the exact curve *and* maintaining it, each different screw would require a different curve.

I had intended adding a few notes on the inapplicability of the chaser, excellent workshop tool though it be, when screw-threads of a high degree of accuracy are required, as it has several inherent defects besides those mentioned by Dr. Edmunds; but I fear I have already occupied too much of your valuable space.

May 6. Canmore.

---

## LATHE MATTERS.

[24243.]—CIRCUMSTANCES have prevented me replying before to the letter of Mr. Hines (24111), and I have only time to say that if he will turn to letter 24072, col. 2, p. 124, and to the first part of letter 23975, p. 60, he will see that I have taken account of the distance travelled by a chuck over the cylindrical portion of a mandrel; and on p. 83, letter 24027, column 3, line 23, he will see the question of time so occupied has not escaped my notice, though this latter being of less importance than centring properties I did not enlarge on it, and therefore these are not new elements. Mr. Hines, in the same letter, also says: "And I have already said that as we extend our bearing surfaces, so we diminish pressure and lessen abrasion." I have tried to prove this on more than one occasion, but I have failed to find any such words in any letters signed by Mr. H., and it seems to me that he has unwittingly quoted from myself; and how Mr. Hines can reconcile this admission with his statement in letter 23838, to the effect that, "if the cylinder-fit was a long, parallel one, as some have suggested" (myself included, I presume), "the wear upon the front portion of it, combined with the wear on the chuck, would be sufficient after a time to render its centrality imperfect," I should like to hear. First, he says that by employing a long cylinder we introduce sufficient friction to wear the parts out of truth after a time; but by using Dr. E.'s short cylinder there would be no real wear. Then he says that by extending the bearing surfaces we lessen abrasion, implying that there was abrasion in a smaller surface, and which might be advantageously decreased by extending the bearing surfaces, and which an increased length of cylinder accomplishes. I hope this criticism will not tend to make Mr. H. abstain from favouring us with his, in many ways valuable, contributions; and if I am shown to have committed an error, I shall be only too pleased to acknowledge it as politely and straightforwardly as Mr. H. has done in letter 24111.

I am very sorry not to have been able to answer Dr. Edmunds' remarks on p. 148 before, and turning to my Fig. 5, p. 83, I think, as mentioned in my letter 24027, that if we take A as a centre about which angular variation takes place, we should find that the opposing surfaces to motion in an upward direction or the reverse of that represented by the hands of a watch are indicated by the lines A B and A C; and if the centre about which variation in truth took place was removed to a point corresponding with A in the cylindrical surface opposite A C, and the motion was in a downward direction or corresponding to that of the hands of a watch, surfaces of exactly similar dimensions would offer opposition. If, however—returning to A—the motion, as in the last case, instead of in an upward had been in a downward direction, surfaces A B and A C would not act; but the opposite cylindrical surface to A C would resist slightly, and A D would do so fully, and precisely similar parts would act in the same way if the motion was an upward one and the drawing turned upside down.

If the centre of motion was at B or D, the whole of B D would or would not act according to the direction of the motion; but whichever way it was, both A C and its corresponding opposite cylindrical part would resist, but only slightly so. If the centre was at C, A D and A C would oppose an upward motion, same as watch hands, and A B and the opposite cylindrical part to A C would oppose a downward or reverse motion, so that there are six points about which variation can take place, and these are in a pair of three each, and the effect of motion upwards or downwards about either three is truly typical of the effect produced by contrary motion about the opposite three. I fail to see that I am wrong, or that Dr. Edmunds has corrected me; but I beg to thank him for his very scientific letter on "Cutting Screw-Threads."

The Laurels, Westbury-on-Trym, E. J. S.
May 5.

## LATHE MATTERS.

[24244.]—In the middle column of p. 190, there is a paragraph commencing, "In 'J. K. P.'s' valuable contribution (p. 149) it is stated," &c. I beg to say that the sentence, as it stands on p. 149, exactly expresses what I meant at the time, and what I still consider to be correct. A cutter is he or that which cuts, and the portion of a cutter that is out of action cutteth not, and for our purpose need not be considered as a cutter at all. Fig. 1 is an illustration of my meaning; *a*, *b*, *c*, being three different positions of the cutter relatively to level of centre line, or, as I commonly call it, centre line, the first-named only being on that line; in which case my contention is not disputed. I also give a sketch or two in illustration of some things that to me appear to take place when using circular cutters, or their equivalents, for shaping different objects. Take, for instance, the action of a cutter, C, cutting a groove in a flat surface, S (see Fig. 2). It is clearly indifferent to the action of the cutter, whether the material, or, say, the work, is drawn along under it from *b* towards *a*, or the cutter itself is drawn along in its supporting frame (not shown) from *a* towards *b*, and supposing the spindle of the cutter to be at right angles to *a b*, the groove at *g*, as shown in elevation, will be a counterpart of the cutter.

Next (see Fig. 3) let the path of the cutter-frame or of the work be still on the line *a b*, but the cutter be inclined to *a b*, at some small horizontal angle, see what occurs. Examining it in elevation, as before, the edge of the cutter, instead of appearing as a vertical line, is changed into an ellipse, and instead of its cutting a sharp V-groove, a counterpart of itself, is producing one with a curved bottom—anything but its own counterpart. It is plain, too, that the larger the cutter, and also the greater the inclination of the cutter to the line *a b*, the greater will be the width of the groove for any particular depth, and, in fact, going to extremes, if the cutter were placed square with *a b*, and gradually sunk up to its axle, it would eventually remove a complete semi-cylinder.

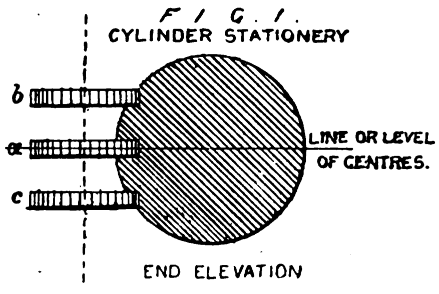

FIG. 1.

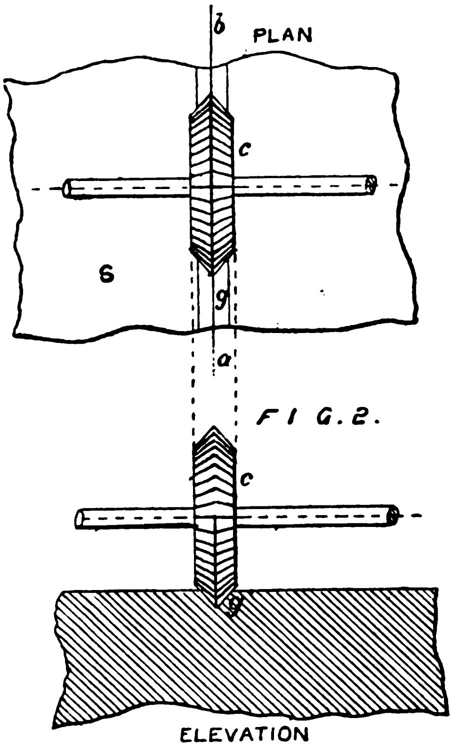

FIG. 2.

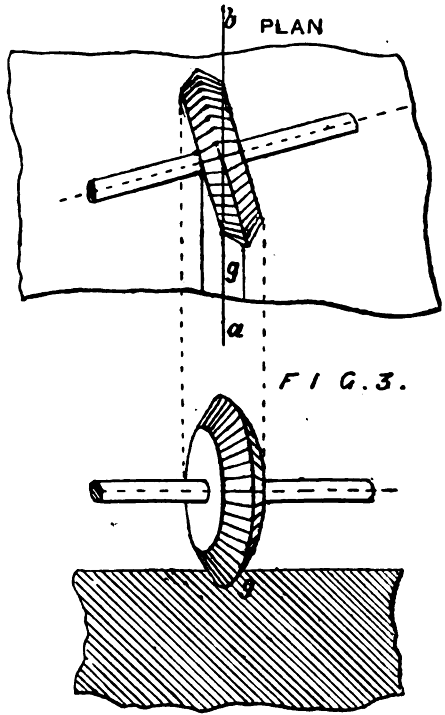

FIG. 3.

In cutting screws by means of circular cutters or grinders of any kind, the above widening of the groove seems to require attention. If you use a V-edged cutter, with its spindle in the plane of the axis of the screw, you will get a groove with its bottom somewhat rounded out, as in Fig. 3, and the section of the thread will be hollowed on the sides. In this case the height of axis of cutter as to centre line needs no attention.

Much less distortion is the result of placing the cutter inclined at the mean angle of the rise of the screw thread, and then I have reason to believe that the diameter of the cutter used is a matter of entire indifference, as to its clearing the cut: that it may not only be made of an infinite diameter, or become a straight cutter, like a file, but may be curved the reverse way, and be as an annulus with internal teeth, and even reduced in diameter, till it assumes the form of a pair of ordinary screw-dies.

In answer to the question on p. 189, near the bottom, "will 'J. K. P.' kindly explain?" Yes, with pleasure, next week. I have got the drawing ready, but it is too rough for engraving, and I could not make a fair copy in time for the present issue.

I think I have already said all required to answer the preceding paragraph, except the last question, to which the answer seems to be this—viz., because the cylindrical fittings are unquestionably better, stronger, and handsomer, and generally more suitable for those particular purposes, whilst it does not appear necessarily a sequitur that they should be the best for all purposes.

In p. 190, half-way down the first column, I can hardly imagine a difference of opinion to exist. Unless I totally misunderstand the subject in dispute, I should say that Mr. Wenham is correct; yet, as I refuse arguing, I am possibly going too far in even expressing my notions on the point.

J. K. P.

[24245.]—I have no desire to maintain a trade squabble with an angry maker of small lathes, as it brings no useful information. Mr. Hines' sense might well remain indicated on the merits of his last letter; but as I am imperatively called upon for some reply, I will answer briefly.

Reverting to the origin of this correspondence as to the circular cutter and grinder for finishing screw-threads, I may say that I have had no reason to deviate from my statement, or "find courage to set myself right." I have consistently stated this cutter to be impracticable and a blunder, and the pertinacity with which it is maintained confirms a doubt of the comprehensive faculty of the proposer. To put the case differently: take a turned rod 1in. in diameter on which a spiral is to be marked, having 8 threads per inch. Now, if a rotary cutter having the width between the threads is set just to scrape the surface, it must be set exactly at the angle, for if either more or less, it will trace a pathway wider than the cutter. Now, if we take another turned cylinder just the diameter reached by the bottom of the V-thread also having 8 threads per inch, a line has to be traced on this with an edge cutter of the same diameter as before. This must be set at a greater angle to the axis; but still it must be exact, or neither more nor less, else, instead of a line, a dimension in width will be the result. It would never make good work to try and give the cutter-edge a twist to meet these two angles, and it is easy to see that every pitch of thread or screw would need a different cutter to get, after all, an imperfect screw-thread. "J. K. P." has pointed this out. It is all very well for Mr. Hines to give him a pat on the back to induce him to see if he cannot alter his statement. As an admirer of his practical sense, I could do this; but I am sure that he has well thought of this before he made the remark, and so the "straw" remains for me to "catch at." Do not be quite so absurd, Mr. Hines; but perhaps your conscience tells you that such remarks are not your own diction.

As to the impracticable and useless mode of grinding up a screw-thread for a finish by a rotary grinder, even if the edge of this is formed so as somewhat to conform to the curved or spiral contour of the thread, we cannot rapidly traverse it to and fro, as is usually done with a free grinder, on account of the backlash of the guide screw of the lathe. The grinder must be entered and readjusted for every run and by the time that it has gone over a thread or so, its line and form will be altered. The admirably terse way in which "Tubal Kain" has put the case in only six lines at the end of his letter in page 215 of last issue, so as to be comprehensible to everyone, leaves but little further to say on this point.

There is no reason why I should not accept the statement that certain makers leave their mandrel-noses soft; I can only remark that I regret that it is so.

To assert that I have "appropriated" a suggestion about tempering mandrels is rather cool. I tempered mandrel-noses this way when this claimant was not out of school, and as mandrels were hardened before I was born, drawing the temper by a hot iron would be on this plan, which any workman would adopt. At the time that I was in business as a maker of machinery, every lathe in my workshop had a hardened mandrel. What kind of lathes? some might say. For screw-cutting lathes I had an 18in. centre, by Smith, Beacock, and Tannett, weighing about 10 tons. A 12in. ditto, by Scriven, and two others for screw-cutting for a 6in. and a 3in. So these were no toys.

I pass over the trade matter in Mr. Hines's letter, and the bounce about the £1,000 challenge, which, having now retired, he is sure I cannot entertain, and for the additional reason that I never made a bet in my life. Diamond-cutting tools act just like any others in the hands of those who know how to use them. As required, I give the names of the lathe-makers who do so. The first is H. Walz, 55, Wallstrasse, Berlin; another is H. Seidel, 158, Linienstrasse. Private inquiry appeared to me to be the proper course; but this was denounced as a "paltry excuse" by a monger in coarse expletives. Further, if any intending purchaser is satisfied with the appearance of these lathes, as shown by the illustrated price lists, I will enable him to see them in use.

And now to "run away" (as they would say) from this peddling drift of the subject. I refer to the letters of "J. K. P." and "Tubal Kain," both evidently practical and familiar with workshop production. I quite agree with their statements, that after all that has been said about the vaunted "model mandrel" (with which we have been so persistently haunted for the past two years) it ends in this, that the angular thread alone, without any cylinder fitting, is the best and truest centring agent, and retains its truth after considerable wear. The threads act as a series of reverse cones, which always bring the chucks in place. The inference is, I suppose, that such screws cannot be cut true: this is a mistake, for with a good screwing lathe they can be made quite as true as any cylinder work. If the finishing cut is taken with a chaser having only three or four teeth kept well sharpened, and used with a very slow speed, even with the back gear on, and fed with oil or suds, the screw will turn out with a brilliant polish, and be made to fit the gauge nut far more accurately than can be effected by any grinding process. At one time I should have made no hesitation in taking the contract for a gross of mandrels, every one of which, when screwed into a test chuck finished in the lathe, should have the free or tail end running absolutely true; as I have said before, there are plenty of light turners who could be trusted with this simple job. Of course, something must depend upon the sort of screw-lathe employed. If this has been unfairly used, and principally for short work close to the mandrel, that part of the leading-screw will have worn progressively, and have an irregular or losing pitch; few old screw-cutting lathes will stand the following test:—Cut a screw on a short piece of metal close to the mandrel end; cut another screw on the end of a rod as long as the lathe will take. If there has been much wear, the threads of these two screws will not fit into each other. My old friend, Andrew Muir, was one of the best screwcutters that I have known; his practice with his own lathe was to have a tie-bar connected with the rest, which enabled him to slip the nut on any part of the screw, and he shifted it periodically, so as to equalise the wear throughout the entire length. **F. H. Wenham.**

### POWERFUL OPERA GLASSES.

[24246.]—Replying to G. Dickson (24217), page 218, I regret to know that he and others have been put to needless trouble and disappointment in the matter of obtaining the powerful glasses provided for them at 117, Victoria-street. It has been caused by the factor so often met with in kindred establishments—popularly known as red tape. The optical department were ready to carry out their part. The secretarial department interposed the law quoted by G. Dickson, not perceiving that I had provided against it by a general order given on behalf of all readers of the "E. M.," to be supplied through my account. I believe, however, that if future orders quote the number 35,462, they will be duly honoured. **Montmartre.**

### THE NEW TIME.

[24247.]—For months and months I have scanned every reference to "new time," as it is called, with the hope of learning the practical utility of the change. At last, we are told, on what I suppose must be confessed to be the sufficient authority of "F.R.A.S.," that the benefit is in the "simplicity of the new mode, and the absolute immunity it affords of all confusion between a.m. and p.m." I do not quite know what "immunity of confusion" may be; but does not that phrase remind you of a well-blown soap-bubble—precious little inside when you have got there? Simplicity! To have 39 figures (Arabic) to look at on a clock-face instead of 15. No one has ventured, so far as I have seen, on Roman figures, always used on account of their plainness. "Immunity from confusion!" (I venture on a correction.) Fancy trying to catch the last train, and wondering whether you had just heard 22 or 23 o'clock striking. Ten or eleven you might have counted and been sure, but with each additional stroke comes increased liability to error. But, oh! dear, to common, ordinary bodies what endless confusion there would be! And all because a special class, whose *forte* is in abstruse calculations, cannot bring themselves down to ordinary life. Didn't Newton sit with his legs in the chest of drawers, and think he had put his trousers away? And is it not on record that he made one hole in the barn-door for the cat and one for the kitten? But we have not thought it necessary to make changes in trousers and barn-doors on account of that little amiable weakness. And can we really think that a man who breakfasts on logarithms and dines on formulas with a little light algebraic refreshment thrown in at intervals during the day, can't find his way about Bradshaw. Surely he must have what he speaks of later in his letter—a craze—to talk like that. Would it be used and sold as it and other railway guides are, if so misleading? By all means, if astronomers find it convenient, let them use their 24 hours; but pray leave us what we consider our sweet simplicity still.

I do hope, Mr. Editor, that you will give me an opportunity of saying so much. I really have waited so patiently to see the advantages of the advocated change, and now I have seen them at last, they seem so very chimerical and unreal, I cannot help expressing an opinion on the other side. **Civicus Olim.**

### MOUNTING BACTERIA.

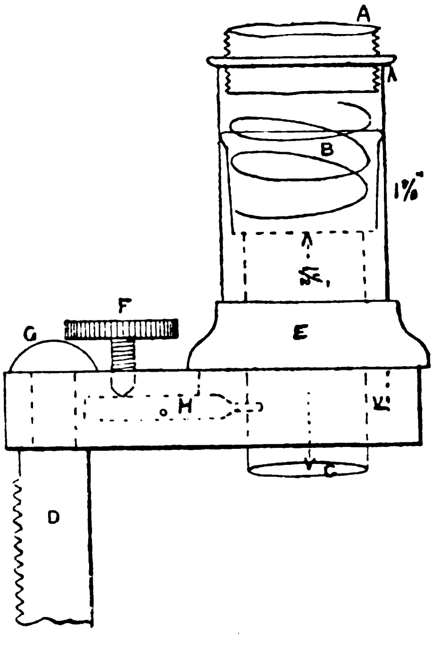
[24248.]—F. Grant, in his very interesting and exhaustive article upon the above subject, appears to assume, as a proved fact, that the B. tuberculosis is contagious. He gives most elaborate instructions for destroying any trace of sputum containing the bacillus upon the instruments used, and to prevent its inoculation upon cuts or the breaking of the cuticle by pricks of needles, &c. Now, I am not one of those who deny that tuberculosis may be contagious; on the contrary, I furnished two cases occurring in my own practice to the Collective Investigation Committee of the British Medical Association, where I believed that the contagion of tubercle had been conveyed to others; but then they were persons who, while in bad health themselves, were for months in constant attendance upon and occupying the same rooms as the invalids, and it must be recollected that out of the large number of replies put in to the query of the Collective Investigation Committee: "Do you believe in the contagiousness of phthisis?" the majority answered "No"; and to the second question asking for particulars of cases proving the affirmative, but a small proportion of the answers could be considered as even approximately conclusive. In fact, any impartial person reading the evidence offered for and against the theory in these replies, must return a verdict of Not Proven. I am aware that tuberculosis can be communicated to some of the lower animals by inoculation, e.g., guinea pigs, but it is not yet a proved fact that the bacillus itself is the *materies morbi*. By many competent observers it is considered that the bacillus will only grow upon a suitable soil, and that no amount of exposure would induce tubercle in a human being who was not, either owing to temporary lowering of the system from other causes, or from a constitutional or hereditary tendency, liable to contract tuberculosis. Whether the bacillus is the cause of the disease or not, the facts hitherto ascertained go to prove that it is invariably associated with it. I should not have troubled the readers of the "E. M." with these observations were it not that it appears to me the precautions suggested by your correspondent, which are right and proper as regards the bacillus of anthrax, and that supposed to cause diphtheria, may convey unnecessary alarm to those of your readers who may have relatives and friends suffering from that dread disease pulmonary consumption, and through them to a larger circle; haunting them while in the presence of the sufferers with the fear of infection, and torturing the minds of the sufferers themselves with the fear that they may communicate the disease to those dear to them. In fine, the balance of evidence at present is to the effect that pulmonary consumption, if communicable at all from one individual to another, is only so under certain combinations of circumstances which rarely occur, and that with proper attention to ventilation and cleanliness, there is no fear of it whatever. Thousands of persons are in daily attendance upon sufferers from consumption, and must, from various causes, both inhale and swallow daily myriads of the bacilli and their spores, and yet of the few hundred medical practitioners who stated they had seen cases where they considered the disease was communicated, hardly any were able to furnish more than one or two such instances out of the many cases they must have attended in the course of their practice. Further on, F. Grant states that the double stain for B tuberculosis with magenta and aniline green is Heneage Gibbes' stain. I shall be glad to be corrected, if in error; but I was always under the impression this was Erlich's, and that Heneage Gibbes recommended solution of chrysoline as a differential stain after first using the magenta. I must say I never found it satisfactory. In conclusion, I must thank F. Grant for the many very valuable suggestions in his paper.

**Medicinæ Doctor.**

## REPLIES TO QUERIES.

**** In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[54721.]—**Micro. Adjustment.**—"Sempervivo" will find the inclosed sketch of a fine adjustment for microscope the simplest and easiest made. The lengths of tube are marked the exact sizes. I shall be pleased to give any other information if he will advertise his address in the "Sale" column.



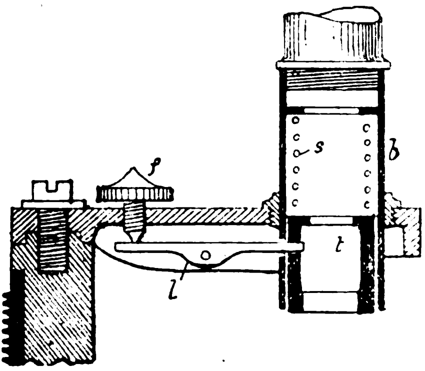
I may say almost any microscope maker will supply the tubes ready screwed if that is a difficulty. A casting screwed both sides, one into body and the other into fine-adjustment tube; B, a tube fitting inside; C, tube for screwing objectives into; F, fine adjustment milled head; E, ornamental base piece; H, lever acted on by F and spiral spring B; D, bar of microscope.—Meniscus.

[54825.]—**Salt, &c.**—"Dens" is surprised why I introduced the "geological strata." Because the lowest forms of men, such as "cave men," river-drift men," the famous "Néanderthal skull," the bones of man recently discovered in the excavations at Milford Haven, &c., are to be found in the "strata." These being, as far as our present knowledge goes, "primitive man," the same strata should show traces of "higher" cultivation or civilisation; while, on the contrary, all we find are "lower" traces—*i.e.*, nothing but chipped flint implements. For if man was created civilised in his primitive state and subsequently deteriorated, became more and more savage, it follows that the tools and implements found along with his remains should be more perfect in the older strata or formations than in the newer. In fact, as we traced up man we should find the scale of cultivation an ascending one, and not as we in fact find it, a descending one. Therefore, it seems to me more in accordance with common sense to believe that all the more perfect forms of life now existing have developed from previously existing lower forms, including man, beast, and plant; in short, that nature's law is uniform.—F. W. H.

[55700.]—**Strength of Shaftings.**—I am glad that the stupidity of the remarks made by "Bacchus," in last week's issue of the "E. M.," has been so neatly exposed by being placed next to the courteous recognition by "Glatton" of my demonstration of the strength of shafting, and my corrections to what I perceive were mere slips of the pen.—G. O. T.

[55700.]—**Strength of Shafting.**—It never occurred to me that the book might be wrong. "That which is in print *must* be true," you know; but I see that it is. Of course, if the strength of the 6in. shaft were nine times that of the 2in. one, they would vary in strength as the squares of their diameter, and not as their cubes, as I have proved they do. It will be noticed that as, before breaking, the outer fibres move through the same distance, *a b* (see Fig. 1, page 174), the smaller shaft moves through a larger angle than the large one, and in designing a long shaft this has to be taken into account, and the shaft made stouter than is required to resist breaking strain, in order to diminish this angular springing.—Glatton.

[55819.]—**Microscope Fine Adjustment.**—I give a rough sketch which will explain the principle of one form: The object-glass screws into the shaft tube *t*; this is made a sliding fit in the body *b* of the microscope, a spiral spring S abutting on a flange in the body pushes *t* downwards. It cannot come out, as a lever *l* holds it up. The screw *f* moves the lever, and with it the object-glass; *c* is the rack for coarse adjustment.—Glatton.



[55835.]—**Workmen's Time Check.**—I cannot find it in my copy of their catalogue; but I believe I have seen the very thing you want in one of Messrs. Bailey's advertisements. Write and ask them. As far as I recollect, a tall clock had a slit in the lower part of its case, through which the men drop their time checks. Beneath this is one of a series of compartments or boxes, which are made on the edge of a small disc or table, which is turned round by the clock. One box is wanted for each period of entry or exit. Of course, when the time is up, the next box is presented to the slit, and receives the "too late" checks.—Glatton.

[55857.]—**Pressure for Stamping.**—Your best plan is to try an experiment. Without that, I can only make a very uncertain estimate. Assuming that the lead crushes with a pressure of three tons per square inch, and that as the die sinks this pressure is increased to, say, four tons, the requisite pressure would be $6 (4 \times 1\frac{1}{2} \times 1\frac{1}{2}) = 54$ tons.—Glatton.

[55875.]—**Cupola Blast.**—To "Invicta."—I have looked in vain for a reply to "Blow Hard's" query. I hope "Invicta" will give the particulars asked for, and, if possible, an estimate of the steam used per ton of iron, as compared with the consumption with a blowing engine. What was the pressure of his steam, and size, and shape of injector?—Glatton.

[56041.]—**Gun-metal.**—Prof. Bloxam, who was lately professor of chemistry in the R.M.A., Woolwich, and in the department of artillery studies, says in his book:—Gun-metal is an alloy of 90·5 parts of copper with 9·5 of tin, especially valuable for its tenacity, hardness, and fusibility. In casting cannon (erroneously called *brass* guns) the mould is placed perpendicularly, &c.—A. R.

[56278.]—**Wood Filler.**—There is nothing better than glue or size, and it must be papered down before applying the varnish.—E. G. M.

[56279.]—**Tennis Grounds.**—Properly laid tar paving will do, but it feels soft in hot weather, and is liable to be broken by the vapour arising underneath unless the ground is well drained and a thick bed of brick or cinder rubbish put under the tar asphalte.—N. E. Child.

[56291.]—**Wheatstone's Bridge.**—To Mr. Barter.—Many thanks for your reply to this query; it has just escaped the U.Q. list. I am afraid I have not made myself understood. What I want to know is this: The least number of Leclanché 7in. cells to measure or balance 500 ohms, having 5 ohms in each left-hand opening of the bridge. Then, how many would do to balance 1,000 ohms, using 10 ohms in each left-hand opening? Not only is it a question of economy, but correctness of result. It is the heating of the coils you mention I wish to avoid.—M.M.I.Sc S.

[56297.]—**Musical Bells.**—How are these bells hung or fixed? That is most likely the place to look for the cause.—F. L. C.

[56309.]—**Parallaxes of Stars,' &c.**—In the reply on p. 197, for "Œltyen" read "Œltzen"; for "ε Eridani" read "e Eridani." The declination of Spica should be − 0° 9'.—H. Sadler.

[56323.]—**Finishing Silver-Plated Goods.**—I was not aware I had promised instructions on this subject. When the articles are removed from the plating bath, they should first be rinsed in clean water, when, if to be left dead white or mat, wash with plain soap and hot water applied with a soft brush, rinse well, and throw into a vessel containing boxwood or other non-resinous sawdust until dry, when beware of fingering the plated parts. There are two other ways of finishing the plated surface—by burnishing with an agate burnisher (made in various shapes and sizes according to requirements), well wetted with soap and water, until quite bright, then finished off with rouge on a leather or wool buff, or on the naked hand. These buffs usually revolve on a lathe. Or the surface may be scratch-brushed, for which I gave full instructions some time since. This produces a bright but dead appearance, and in connection with the bright polished surface looks very well. Or, again, oxydising or gilding may be introduced. If you want any more hints, please state in what direction you require them.—Goldsmith.

[56332.]—**Optical.**—Many thanks to "T. H. L." I think his reply to this, on page 176, answers my query, No. 54318, page 499, Vol. XXXIX., and I conclude that it is impossible to adjust my Abney's level so as to be correct in more than three positions. As the formula is rather a long one, perhaps "T. H. L." could tell me without working it all through, at what angle I should take $\phi$ in his figure in order that $b$ may be about the mean of the position it may assume, while $\phi$ varies from 0° to 45°. Also if it varies from 0° to 90°. It looks as if A $b$ must cut the vertical line between D and Y if it is normal to an ellipse, the minor axis of which lies along D$x$, which, I suppose, it must do if D is the centre and B the focus. Perhaps it is normal to the further side of the ellipse.—Glatton.

[56340.]—**Query Meaning.**—The error is a very common one, and is caused by looking at the figures the wrong way. Thus, if B. makes an article for £50 which A. makes for £100, B. is apt to say that his is 100 per cent. cheaper, because £100 compared with £50 is 100 per cent. advance, whereas of course he should say that £50 is only half of £100, and therefore the article is only 50 per cent. cheaper—or what is more likely, lower priced.—F. C. A.

[56365.]—**Flat Foot.**—I sympathise with "Flat Foot," having myself suffered in the same way for two or three years; but now I may say I am quite well, except when going down a bank or having walked more than usual, but have a good deal of walking every day. The way I got my trouble was by lacing my boots too tight. When the bone-setter got hold of my foot he asked how long I had suffered, and I said about seven months. "Over long," said he. He then said there was a small bone had got out of place, and it would now be bad to get in and keep it so, as it was where a bandage could not well touch it, and his being a cotton cloth one, it would be of little or no use. I had water run on my foot, and other such things, but to no purpose. I at last got some elastic webbing and fastened it round my ankle, which gave me a little benefit, but found the tapes to fasten it round my ankle prevented me getting the use of the elasticity, which I found was what I wanted. I afterwards took off the tapes and put on some hooks and eyes to fasten the bandage, and with a tape stirrup to go underneath the foot. After wearing this out I went to buy more. However, I got this time some "indiarubber band," about 3in. wide, not webbing, about a yard long, for 2s. 6d., which I found to be the best thing I could get or use. When I first put it on I was delighted. I put this bandage on thus: One end on top of the foot, and brought the other part over it and round the ankle twice, then again round the foot, and finishing off on the top of the foot; not too tight, but the weakness being near the under part of the ankle, I used to pad it a little with cotton wool. The elastic band did not require anything to fasten the end, as it was adhesive enough, and I got the full advantage of the elasticity. I wore it daily, and often at night also; at first I could not sleep without it. I used it thus till I was quite freed from pain, &c., and now do without it altogether. I have since worn shoes only, but not made in any extraordinary way. Hope this may be of service.—J. D.

[56379.]—**Bichromate Battery for Lighting.**—If the leakage is of no consequence, why not remove the partitions altogether? In my opinion it is one of the two causes of failure. By uniting the two liquids in the ten cells, it converts the whole into one large cell, the useful elements being the two to which the wires from the lamp are connected; all the rest are wasted. "Accumulator" says we should get more current than one cell would give. Why? By having ten times the thickness of liquid between the plates, we should get ten times the resistance of an ordinary cell, and consequently only one-tenth of the current; but, besides this, the wooden partitions tend to further increase the resistance, as the only useful electrolyte is that passing through the leaks—which I take to be very small—thus reducing the current to a very small fraction. I should like to hear "Accumulator's" reasons for this statement. "In the Dark" asks "whether the carbons, being larger than the zincs, are not sufficient?" &c. It does not matter about the carbon being larger, as only that portion of it which stands exactly opposite the zinc is sensibly acted on; so that by using two carbons he would get double the useful surface. This is advisable; not necessary. There are so many different bichromate solutions, that it is difficult to say which is best. The following, I think, is fairly good:—"To every pint of saturated solution of bichro., add one fluid ounce of sulphuric acid. Assuming that each of your cells will give 1·8 volt E.M.F. (which I question) and that the resistance per cell is ·5 ohm; at the best, you can get 16·2 volt-ampères (watts) useful energy, which would mean, taking 2½ watts per candle, about 6 candle-power. This would be when the resistance of the lamp equalled the resistance of the battery, so that 50 per cent. of the total energy would be expended in the battery.—Frank Broadbent, Cadby Hall Works, Hammersmith.

[56383.]—**The New Station at Birmingham.**—I should be greatly obliged if H. W. Hudson (p. 177) would say how long the platform is at the new station, Birmingham?—A. B.

[56387.]—**Medical Coil.**—Yes, you can charge with the bichromate solution; but you must take out the zincs from the liquid when not in use, as the solution acts upon the metal, whether the cell is at work or not. If your plates are fastened to the cover of the cell, you can easily lift the whole arrangement out without trouble. The solution should be composed of ¼lb. bichromate, ¼lb. sulphuric acid to 1 pint of water, and not as printed in my previous reply. As the surface of the elements is very large, the current may be too great for your purpose. If so, you can dilute with a larger quantity of water.—C. D. R.

[56393.]—**Steam.**—With steam more than 12lb. pressure above the atmosphere, the weight that will escape from an orifice one square inch area in 70 seconds, is just equal to the gross pressure in pounds per square inch. Then for a pressure of 50lb., and an orifice of 2½in. diam., the weight of escape per minute will be—70 : 60 : : 65 = 55·7lb. per square inch area of orifice, and 55·7 × 4·9 = 273lb. escape per minute.—Yama.

[56404.]—**Overflow in Water-waste Preventer.**—The best thing will be to send the waste preventer to the maker, as I fancy the outlet valve has got loose, or that it is improperly fitted; perhaps the ball valve is out of order, or if it is a siphon waste preventer, probably it is air bound—viz., the supply pipe to closet may form a trap below the closet seat, which would have the effect of continual leaking.—P. J. Davies.

[56404.]—**Overflow in Water-waste Preventer.**—I asked for information how to remedy overflow in water-waste preventer which was trying to run cistern dry by perpetual waste. As the w.w.p. is likely to become a necessary institution in every household by Act of Parliament, I will (in the absence of reply from any expert) answer my own query myself. The reported overflow not only continued, but was supplemented, first, by a constant waste-stream through the pan as well, and finally by a third unascertained manner of overflow, which came down through the house in spite of the overflow pipe. At this stage, I forced down the feed ball cock about half an inch, so lessening at same time the power of the flush-charge by decreasing its quantity, but effectually curing all three forms of overflow. Our readers may possibly think it natural that the maker should be applied to to remedy the defect. It is, therefore, well they should know that by the rules of the trade the wholesale maker is forbidden either to remedy a defect himself, or to supply the name of a plumber who understands the instrument! Messrs. Bolding, the makers in this case, are my authority for this curious fact. Householders are thus forced, as I was, to send to promiscuous plumbers, who will "send a man to see." I tried three firms in succession, and paid three bills for unsuccessful services, before I wrote to the "E. M." for relief. I presume there is a regulator to effect what in my ignorance I attained by force. This answer is, therefore, unsatisfactory, though it is better than silence.—Montmartre.

[56461.]—**Pressure on Sides of Tank.**—The pressure on the sides or ends of a tank or vessel is equal to the area in feet multiplied by the height of the centre of gravity in feet, then multiplied by the weight of a cubic foot of water. For example: Find the pressure on the sides of a tank 10ft. deep and 12ft. long.

Area of side 10 × 12 = 120 sq. ft.

Now, since the centre of gravity is half the height (5ft.), and a cubic foot of water weighs 62·5lb.—

$$\therefore \text{ Pressure on sides} = 120 \times 5 \times 62{\cdot}5 = 37{,}500\text{lb.}$$

$$\therefore \text{ Average pressure on the square foot of side} = \frac{37{,}500}{120} = 312{\cdot}5\text{lb.}$$

If it be 8ft. wide, the pressure on the end is—

$$= 8 \times 10 \times 5 \times 62{\cdot}5 = 25{,}000\text{lb.}$$

—C. E., jr.

[56446.]—**Cement for Rainwater Pipe.**—Paint the pipe and get a piece of zinc two or three inches longer than the crack in the pipe, and also paint that, then with some red lead putty, bed the piece of zinc closely on to the cracked pipe and tie it on with string or wire, after which paint the zinc to match colour of pipe. This, if properly done, will last a long time, and not look unsightly.—P. J. DAVIES.

[56464.]—**Ammeter.**—By tapping the key before permanently closing the circuit, the violent swing is avoided. A little practice only is necessary.—F. BROADBENT, Cadby Hall Works, Hammersmith.

[56476.]—**Incandescent Lamps.**—The reason that the carbon filament is consumed is that the carbon combines with the oxygen of the atmosphere to form a gas, carbonic dioxide (carbonic acid).—FABER FABRUM ADJUVET.

[56476.]—**Incandescent Lamps.**—The filament being only about the thickness of thread, would naturally be consumed almost immediately in air. This is why the lamp is exhausted.—FRANK BROADBENT, Cadby Hall Works, Hammersmith.

[56479.]—**Surface Condenser.**—The proper temperature at which to keep the condenser is as near as possible 100° Fahr., or 38° C. At this temperature the steam is sufficiently condensed, while the air-pump has relatively the least quantity of water to raise, or with a maximum amount of useful condensation we have a minimum amount of water to lift. The condenser being maintained at the above temperature, and the condensing water at 10° C., we get the amount of water required for condensation by the following calculation: The total amount of heat in a given unit of steam is 637·2 units C. The amount imported to each unit of water is $38 - 10 = 28$ units C. of the 637·2 units of heat in each unit of steam, it must give up $637{\cdot}2 - 38 = 599{\cdot}2$ units. ∴ The units of water required—

$$= \frac{599{\cdot}2}{28} = 21{\cdot}4,$$

or a cubic foot of steam, as it is produced (very nearly) by a cubic inch of water, will require 21·4 cubic inches of water to condense it. More, however, is always allowed, because it is impossible so to arrange the condenser that every drop of water shall at once consume its allotted amount of heat. The area of the condensing surface per I.H.P. is from ·2 to ·25 square feet.—C. E., jr.

[56483.]—**Linkwork for Slide-Valve.**—I inclose a sketch of Webb's patent link-reversing motion (L. and N. W. R.) The peculiarity of this motion is in the link, which is straight instead of being in concave or convex curves to the driving shaft, like the Stephenson and Gooch links respectively. On moving the lever A (see Fig. 1) in th direction indicated by the arrow, the lever B moves forward, turning about the fulcrum C, and this motion given to D causes it to move another lever E, to which the arms G and F are rigidly fixed; the whole of E moving about the fulcrum H. Thus, when E moves forward, the arm F is lowered and G raised, causing the rods K and L respectively to fall and rise. Now, L is attached to the link M, and K to the connecting rod N, which is hinged to the valve rod, and, therefore, when K and L are lowered and raised respectively, the link M is raised while the connecting rod N is lowered. Locomotives can be reversed when in motion; but when this is attempted, the framing of the engine is subjected to very great strains; for an engine, going at even the lowest speed, will have a certain amount of inertia, and will not, therefore, "pull up short" by itself directly steam is cut off. But now, if steam be not cut off, and the engine be reversed, steam is admitted into that end of the cylinder towards which the piston is being forced, due to the inertia of the engine (see Fig. 2); *a*, *a* is the steam entering the cylinder, and *b* is the force which is pushing the piston back, due to the inertia of the engine. Therefore, it is evident that the whole frame, and especially the piston-rod, is being subjected to very heavy strains; in fact, the engine may be said "to be working against itself," and, therefore, it is not advisable to resort to this mode of stopping the engine, except under the most pressing circumstances. With regard to "Linkwork's" observation of the driver pulling the reversing lever while the engine is in motion, it is quite possible, and very probable, that he would do so if the engine were going at full speed, because less steam is then required to keep up that speed than was required to start the engine and get up such speed; he would, therefore, move the link into mid-gear, so that the travel of the valve should not be so great, and, therefore, less steam would be admitted. In other words, he would be economising his steam. I think, too, that in this case "Linkwork" would have observed that the driver did not move the reversing lever from one extremity of the quadrant to the other extremity, but only moved it about half-way. But, on the other hand, if the engine were only being used for shunting, the driver might already have shut off steam when "Linkwork" observed him to reverse his engine; in which case there would be no strains whatever acting upon the piston-rod, &c —W. J. A. W.

FIG. 1.

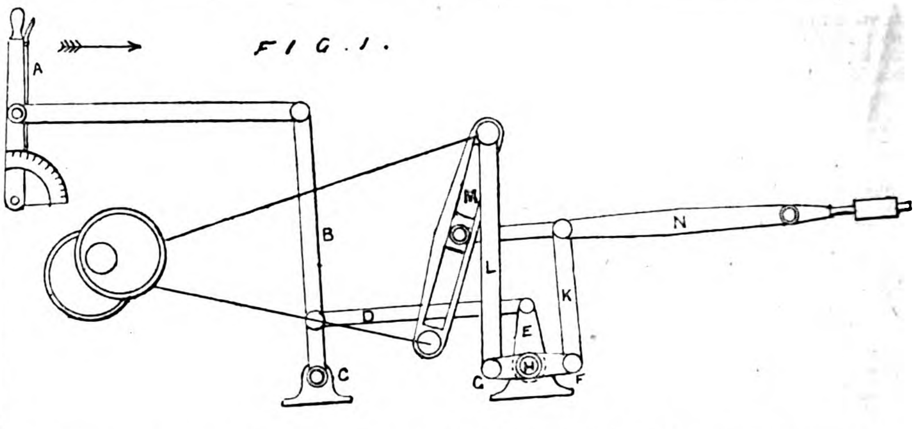


FIG. 2.

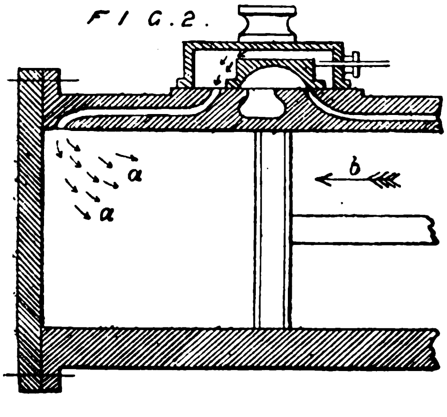


[56484.]—**Varnished Wall Paper.**—To endeavour to clean "dirty, smoky wall paper" with a rag and paraffin oil is simply nonsense. "Nun. Dor." should read queries before he attempts to reply. Wash well with strong soap-and-water, rinse with clean, and wipe off with a wash-leather, and avoid all streaky marks. You might as well clean dirty windows with paraffin oil as dirty wall paper.—C. D. R.

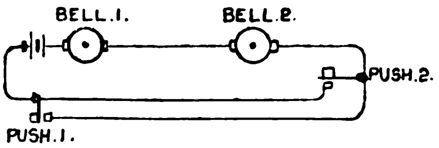
[56485.] —**Model Boat.** — Many thanks to "Invicta" for answer, which told me the very thing I wanted. I may state that the boat must be rather strong than elegant. Some "notion," assisted by spring and clockwork, is expected to make it go at the rate of eight miles an hour. I shall be glad if it does.—VIRAGO.

[56488.]—**Zinc Battery.**—Using zinc cylinders instead of rods would decrease the resistance of the cells, and they would, therefore, give you more current.—FRANK BROADBENT, Cadby Hall Works, Hammersmith.

[56488.]—**Zinc Battery.**—What do you mean by chloride of zinc battery? Is it the cell with chloride of zinc as the excitant, and bichromate of potash and hydrochloric acid as the depolariser? No matter what cell you construct, the negative element should be of larger dimensions than the positive. If, therefore, your carbons are small, the increase in the surface of zinc over and above them is simply waste.—C. D. R.

[56491.]—**Long Distance Electro-Magnet.**—The query is very ambiguous. Explain what you require the magnet for.—G. D. R.

[56499.] —**Electrical.** —The simplest (and I think the only) way would be to connect the bells as in the diagram. Two wires are necessary, unless you can put one to earth. Both bells will ring together.—FRANK BROADBENT, Cadby Hall Works, Hammersmith.



[56500.]—**Gravity Leclanche.**—I think this would be an excellent cell, both as regards cheapness and efficiency. I do not think the carbon wants insulating at all—in fact, the more exposed the better. Look at it for a moment as a zinc carbon element: the carbon in this case produces (so to speak) current; insulate it, and the cell would be useless. The carbon, mind you, must not touch the zinc, or it would be short-circuited. It would be very easy to clean (this cell) by upsetting the peroxide of manganese and crushed carbon into a jar, well washing, and repacking; new surfaces would be exposed. I never saw cells of this pattern, but shall make some shortly. Meantime, I hope we shall have the opinion of an authority—such as "Sigma."—M.M.I.Sc S.

[56502.]—**Faulty Dynamo.**—To MR. BOTTONE.—Will this correspondent kindly explain the last sentence of his reply to this query on page 222? What do M and A represent? If they are the resistances of field magnets and armature, what is R?—WM. JOHN GREY, F.C.S., Analytical Chemist, Newcastle-upon-Tyne.

[56510.] —**Extra Strong Magnets.** —The formula for finding the lifting power *p* of a magnet whose weight is *w*, is given by Ganot and Guthrie as—

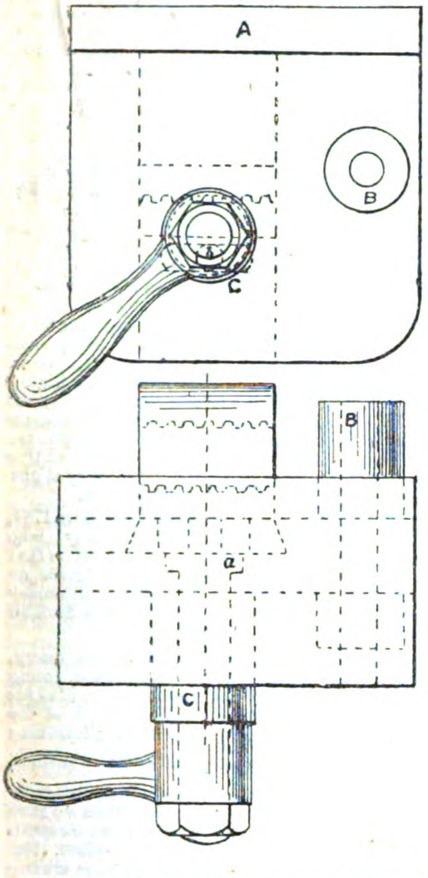
$$p = a \times \sqrt[3]{w^2}.$$

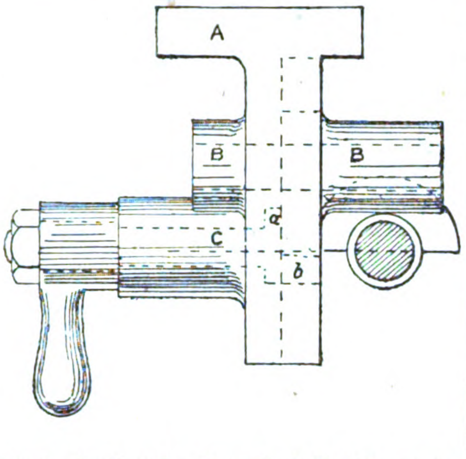
Where *a* is some constant whose value varies considerably for different kinds of steel. It may be as high as 23, so a magnet which lifts only ten or fifteen times its own weight would not be anything extra. Guthrie remarks that this formula requires confirmation, and Silvanus Thompson reverses the indices, which alters the expression entirely. The last-named scientist states that the pull of an electro-magnet on its armature may amount to 200lb. per square inch.—WM. JOHN GREY, F.C.S., Analytical Chemist, Newcastle-upon-Tyne.

[56512.]—**Diamond Tools.**—"T. W." asks for particulars of a machine wherein to use a little piece of carbonado to dress a millstone. The expired patent of Young, A.D. 1868, Feb. 12, No. 475, carried this out. Young described his tool as "what is ordinarily called the black diamond, or carbon, and is met with in Brazil, Siberia, and elsewhere in the form of small rough, dark or 'dull-coloured' stones." I know that many machines were worked, but whether used now or not I do not know.—R. S. T.

[56512.]—**Diamond Tools.**—The dividing frame used for traversing the diamond for refacing or "cracking" the surface of millstones consisted of a dividing and traversing slide at right angles, worked by screws like a slide-rest; this was clamped in place by a cross-bar extending over the stone; the rest did not have to stand much stress from the work done by the diamond, as this acted by the momentum of rotation, just in the same way that a fly-cutter turning on hardened centres is used for grooving. The way in which the diamond was securely held in order to perform the enormous amount of work that it had to do was peculiar. Want of time prevents me from going into the particulars of this just at present, but in my promised article on the use and means of setting diamond turning tools accurately I will explain fully. In the mean time I see by the leading article in the last issue of this journal, on "The International Inventions' Exhibition," that the Waltham Watch Co. use sapphire cutters for making the teeth of their escape wheels. This, though inferior in hardness to diamond, would still maintain an almost everlasting keen edge on steelwork, and a great advantage in both diamond and sapphire tools is that they do not get softened and lose temper at quick cutting speeds, like hardened steel does.—F. H. WENHAM.

[56506.] —**Pattern Making.** —The annexed figures illustrate a plate adapted for use with your slide rest; but the centres and depth will be regulated by the position of your leading screw and rack in reference to each other, and to the bed, and not knowing the section of your bed, I forbear to give dimensions. The flange A affords the means of attachment to the under part of the saddle. The





boss B is for the spindle of the rack pinion. The boss C is for the spindle which moves the half-nut. The spindle is prevented from slipping out by the collar *a*, and the pin *b*, set eccentrically with the spindle, slides in a slot in the plate which is attached to the half-nut, and moves it up sufficiently to clear the screw. The rack should be 7-16in. or $\frac{1}{2}$in. pitch, and screwed under the front bed vee with stove or cheese-headed screws. You can reduce the shape of their teeth from Fig. 59, on p. 161 of of the present volume. The usual set of engineers' change wheels runs from 20 to 120, advancing by fives, which, with one duplicate, makes 22 in all.—J. H.

[56513.]—**Chemical.**—I should imagine that the sample of hydrogen peroxide which jellifies on the addition of ammonia, contains barium chloride in solution, derived from the barium peroxide from which it has been made, and which ought to have been removed from it by the maker.—G. H. HURST, Salford.

[56515.]—**Lead Burning.**—I cannot understand your chamber being full of acid. I generally stop my leakages with china-clay putty, or to stop the fume leakages I take some stiff brown paper covered with pitch. See page 70, Davies's "Plumbing Work."—P. J. D.

[56516.]—**Disabled Marine Engine.**—If one engine was damaged, the disabled one should be disconnected, and proceed with the other. But it sometimes happens where there is much lead upon the slide-valve, that the single engine on being started cannot be got to turn the centre if there be a strong opposing wind and sea; the piston going up to very near the end of stroke, and return again without clearing, or being able to turn the centre. In such cases it is necessary to turn vessel's head sufficiently from the wind to enable some sail to be set, and if once there is way got upon the vessel, the engine will begin to work properly, and will continue to do so, though the vessel be put head to wind as before. If the crank-pin breaks in a paddle vessel with two engines, the other engine must be made to work one wheel. In a screw vessel the same course may be pursued provided the broken crank is not the one through which the force of the other engine is communicated to the screw. A very good book on the marine engine can be had for 6s. by Ainsley: it is called "Ainsley's Engineers' Manual of the Local Marine Board Examinations."—I. H. E.

[56520.]—**Gasoline Generator.**—In reply to "E. C.," the quantity of gasoline taken up by air varies according to the temperature of the air, and also of the gasoline. Under ordinary average conditions, about 250 cubic feet of air will take up one gallon of gasoline. I have no data at hand which will enable me to give the required quantity of air to make this into a perfectly explosive mixture, but should think that the quantity of air will be nearer ten than five times the bulk of the vapour.—T. F.

[56521.]—**Jupiter's Transits with 3in. O.G.**—With a 3in. achromatic telescope, power 200, I have witnessed the transit of Satellite III. and its shadow; my eye was kept at the telescope the whole of the time the Satellite was crossing the disc of the planet, but not quite to the end of the shadow. Satellite and shadow were perfectly visible and sharply defined during the course of their transit. The most satisfactory answer to this query is for "E. P. B." to try for himself what can be done in this respect with his $2\frac{3}{4}$ o.g. My own experience is that a moderately low power is better for these details than a high power.—S. S., Southampton.

[56530.]—**Pallet Holes for Harmoniums**—If this querist had stated what sized reeds he intended to use, a more definite answer could be given; but as a rule two-thirds the length of the vibrator and just clear in width will do. In practice, of course, the smaller reed holes are cut much wider than they need be, because it is too much trouble to change the bits. Here are the usual dimensions for 16ft. and 8ft. reeds. For 16ft., 1st C $1\frac{3}{4}$in., 2nd C $1\frac{1}{2}$in., 3rd C $1\frac{1}{2}$in., 4th $1\frac{1}{8}$in., 5th 1in., 6th $\frac{7}{8}$in. Drill all the bass holes with $\frac{1}{4}$in. bit, and clear out for lowest notes; drill treble with $\frac{3}{16}$in. bit. For 8ft. 1st C $1\frac{1}{2}$, 2nd $1\frac{5}{16}$, 3rd $1\frac{1}{8}$, 4th 1, 5th $\frac{3}{4}$, 6th $\frac{5}{8}$in. Pallet apertures for 16ft. set may be from $\frac{1}{2}$in. to $\frac{1}{8}$in. shorter, ranging from lowest note to top; for 8ft. about $\frac{3}{8}$in. to nothing shorter, all graduating in between. Reeds should be screwed firmly to pan with the tip of vibrator just clearing the end of hole. The American organ valve action was illustrated in No. 1027, and in many other back numbers.—N. E. CHILD.

[56534.]—**Powers of Opera Glasses.**—"Devoniensis" asks how the powers are ascertained. By putting one barrel only to one eye and comparing the size of the image shown through it with the size of the same object as seen by the other eye at the same moment. Thus a ten-power glass will show through one barrel directed upon a thermometer across a room, one degree of its scale, in exactly the same space as ten of the same degrees occupy as seen by the other eye at the same moment. By a little care and practice the two pictures may be brought side by side at once, or one may be superposed on the other, so that if the power of the glass happened to be either $9\frac{1}{2}$ or $10\frac{1}{2}$ instead of 10 exactly, the difference would be at once observed. In the same way different opera-glasses should be compared with each other for power by placing one barrel of each opera glass to the two eyes simultaneously, when the great difference between the powerful and ordinary glasses will be appreciated as the two different-sized resulting pictures appear side by side. I once walked from St. Paul's to Charing-cross and compared the 4, 7, and 10 power glasses with the stocks of the opticians on both sides of the road without finding one single glass to approach them in power.—MONTMARTRE.

[56537.]—**Railway Distance.**—The actual distance between Lime-street and Euston (viâ Crewe and Runcorn) is 193 miles 49 chains.—H. H. B.

[56541.]—**Experiments with Magnetic Machine.**—The only experiment to try with this machine now you are tired of it is to endeavour to convert it into something else through the medium of the Sixpenny Sale and Exchange Column.—C. D. R.

[56541.]—**Experiments with Magnetic Machine.**—These machines, as usually made, cannot be used for any other purpose than giving shocks. They will neither fire gunpowder, nor light the smallest lamp, nor work models. They won't even ring an ordinary bell. Of course, we can hardly blame the machine, as these are purposes for which it is never made. If you are anxious to show your friends a few beautiful experiments, use an induction coil or an ordinary plate-glass machine.—BOBADIL.

[56543.]—**Carpenter Brake.**—The Carpenter brake is practically the Westinghouse *without* the triple valve. This absence of triple valve renders the movement of a large quantity of air necessary, and causes it to be slower in its action.—BRAKE.

[56544.]—**Coulomb or Weber.**—There is no difference: the Weber is the old name for Coulomb, and equals $10^{-1}$ C.G S. units.—F. L. T.

[56544.]—**Coulomb or Weber.**—A coulomb is a unit of quantity, and a weber is (or at least was) a unit of current. A unit current is now called an ampère, and transmits a coulomb of electricity per second. It is the current yielded by a potential of one volt through a total resistance of one ohm.—WM. JOHN GREY, F.C.S., Newcastle-upon-Tyne.

[56544.]—**Coulomb or Weber.**—The weber is an absolute unit, and has been supplanted by the coulomb, the unit of quantity of electricity passed in one second by one volt through one ohm, and the ampère the unit of current at a rate of flow of one coulomb per second. Each is equal to $10^{-1}$ or $\frac{1}{10}$ of an absolute C.G.S. electro-magnetic unit.—EUGENE BROWN.

[56544.]—**Coulomb or Weber.**—There has been some confusion in the use of the term "weber." Sometimes it stands for one-tenth the absolute unit of quantity, and sometimes for one-tenth the absolute unit of current on the electro-magnetic system of units. It is best to keep to the terms "coulomb" and "ampère," as is now generally the practice.—L. EDMUNDS.

[56545.]—**Real Name.**—The baptismal name is the legal name. I say this because a form is supplied to effect the alteration of the entry in the registrar's books when a mistake has been made or a change is desired. A name given at baptism in the Church of England cannot be altered except by the Bishop at Confirmation.—VICAR.

[56545.]—**Legal.**—So far as the legality of the registered name and the christened name of a child (when they differ) is concerned, the registered name is the legal one, and parents should call the child by the latter to avoid future trouble; but suppose the child has grown up, and is and has been all along known by the christened or any other name, that will be now the legal name. If for the purpose of insurance or legal documents it is necessary to connect the registered name and the now "habit and repute" name, affidavits will require to be got from parties who can testify that both names apply to the same person.—B.Sc., Plymouth.

[56546.]—**Magnetic Moment.**—Everett's definition is perfectly right, and means this: The magnetic moment is equal to the product of the intensity or strength of either pole into the distance between the poles. The strength is measured in dynes, and the line in centimetres. So we have, Moment = 3 × 10 × 10 = 300 c.g.s. units.—F. L. T.

[56546.]—**Magnetic Moment.**—G. Park will find a complete and clear explanation of the terms that puzzle him in the supplement of the new edition of Guthrie's "Electricity and Magnetism." The supplement is written by C. V. Boys. S. P. Thompson's "Elementary Lessons in Electricity and Magnetism" may be mentioned as another good book to consult.—T. JONES.

[56546.]—**Magnetic Moment.**—The magnetic moment of a magnet is expressed by $m\,l$, $m$ being the strength of one of the poles, and $l$ length of magnet. In the formula $m\,l\,H$, $m\,l$ is the moment of a couple tending to turn the magnet into the magnetic meridian, H being the horizontal component of the earth's magnetism. The answer 300 would be obtained thus: 1 decimètre = 10 centimètres; 3 × 10 × 10 = 300. The units being dynes and centimètres.—EUGENE BROWN.

[56546.]—**Magnetic Moment.**—Maxwell says, "The product of the length of a uniformly and longitudinally magnetised bar magnet into the strength of its positive pole is called its magnetic moment." As a matter of fact, it is only in the limiting case of a very long and thin bar of iron that a near approximation to uniform and longitudinal magnetisation is made. The magnetic moment of a magnetised bar of iron is, however, a quantity independent of the strength of the poles, which we scarcely ever know or are able to determine with much accuracy. It may be found by experiment. The magnetic moment we then find is the couple which a uniform field of unit intensity would call into play when the bar magnet is placed perpendicular to the lines of force in the field. There is some mistake in the question which relates to a magnet of which the pole strength and distance between the poles is supposed given. The magnetic moment is 3 × 10 = 30; but the couple acting on the magnet when at right angles to the uniform field of force of strength 10 is thus 30 multiplied by 10.—L. EDMUNDS.

[56546.]—**Magnetic Moment.**—The moment of a magnet is very much the same thing as the moment of a "couple" in mechanics, and is the product of the strength of a pole by the length of the magnet. According to the C.G.S. system of units, the length is measured in centimètres, and the strength of the pole is given with reference to the unit pole, which is of such a strength that when placed one centimètre from an equal pole it repels it with a force of one dyne. A dyne is the force which, by acting on a mass of 1 gramme for 1 second, would impart to it a velocity of 1 centimetre per second. A gramme is equal to about 981 dynes. In the question given, the magnet is 100cm. long, and its poles being 3 units, its moment is of course, 300. The field intensity has nothing to do with the matter. Moreover, the intensity of a field cannot be expressed in dynes, because the dimensions are different. A dyne is a unit of force, and its dimensions are $M L T^{-2}$; but a field intensity is equal to a force divided by the strength of a pole, and its dimensions are $M^{\frac{1}{2}} L^{-\frac{1}{2}} T^{-1}$.—Wm. John Grey, F.C.S., Analytical Chemist, Newcastle-upon-Tyne.

[56547.]—**Geometrical.**—Call the four lines *a*, *b*, *c*, *d*, respectively; then, taking them three at a time, we get the four triangles formed by *a*, *b*, *c*; *a*, *b*, *d*; *a*, *c*, *d*; *b*, *c*, *d*. There are no other triangles possible.—L. Edmunds.

[56547.]—**Geometrical.**—"J. C.'s" difficulty will vanish if he regards the sides of any quadrilateral plane as being the bases of four triangles formed by four lines drawn from any point in that plane. Of course, he will now at once see that Todhunter's enunciation amounts to this: If in any quadrilateral plane four triangles be drawn having a common apex and the sides of the plane for their respective bases, then show that the circumscribing circles of these four triangles will pass through the common apex. This, from the construction, is self-evident; but may be proved by the method of "reductio ad absurdum." — Ex-Blacksmith, Gorton Brook.

[56548.]—**Ferro-Prussiate Copies.**—In reply to "W. T. B.," I have used the above process to copy various articles, such as lace, leaves, flowers, &c. I have never noticed anything of the kind with my blue photos. After exposure I simply wash the prints in cold water for about five minutes, and then dry between blotting paper.—Prussiate.

[56548.] — **Ferro - Prussiatic Copies.** — "W. T. B." probably stops the printing too soon; if so, he will obtain a light blue print, pleasing, but fugitive. After exposure to light the paper should have a greenish-blue tint, then a light brown, afterwards a darker brown, changing to olive. If stopped at the greenish-blue or light brown the colour will fade; but I have not found it do so when washed from the dark brown or olive tint.—Acier.

[56549.]—**Bronzing Iron.** — Why not paint them with varnish, and then dust on some bronze powder when the varnish is all but dry.—Lustre.

[56550.]—**Sawing.**—To "Alabama."—"Alabama" does not mention what kind of sawing it is that he has been trying to do; but what I can see of it it must be pit sawing, according to the way he asks his query. He is very likely a wheelwright by asking the other query on repairing old wheels. If he is, and he thinks of starting to cut his own stuff, he will find his mistake out, and be at a loss. For instance, suppose you have a log of ash 20ft. long, and 2ft. through it, and you plank it, and there is 480ft. of sawing in the log at 6s. per 100ft., and that is a very good price, as I have known my father cut it at 3s. 6d. and upwards, and I myself have cut thousands of feet at 4s. 6d. per hundred, and that would amount to £1 2s., so that if your ash was worth 9d. per foot for 2in. plank, and you spoiled only one plank at 2ft. deep, that would be £1 10s., that would be 8s. more than paying a good price for someone to do it well, so that if "Alabama" will take my advice he will let it alone, as it is no amateur's job. There requires more skill in pit sawing than any trade I know of. If a good machine sawyer takes to it he would not manage it unless he has done some before, because he would find that the sharping would not do, and it would not do for the vertical frame only, for being cottered up tight, and an engine to do the labour, and yet some of them will say the engine has not enough power. What I want to know is—how is it that two men have enough power? as I have worked where there has not been enough power till I have gone, and then it would drive an extra bench. But, as "Alabama" says, we get on all right for about 12in., and then hollows ½in.; he is wrong, for it will be inclined to go from the start, and if he will pull the saw back, so that he can see down the cut, he will see that it starts from the beginning, and it is sure to twist as long as it hollows, and it is no fault of the saw, unless the saw is buckled, nor yet the men; but it is the man's fault that is on the top, as he does not put the saw to work proper, and that is a difficult job for an amateur, and a great many professional workmen. I don't wonder at it being hard work when it hollows ½in., when it is hard work if it is hollowing only $\frac{1}{16}$in. If it hollows only $\frac{1}{16}$in. a man cannot do a day's work, which is from 100ft. to 200ft. per day. As I am cutting, and have cut, some of the largest English timber that has grown, and will give some information to "Alabama" if he will state what he is cutting, and what depth of top, length of saw, gauge of saw, and space of teeth. Please advertise your address, and I will do what I can for "Alabama."—J. M., a Sawyer.

[56558.]—**Lincoln Cathedral.**—The beam referred to is a long, slightly-arched, slender beam of stone, which transmits the thrust from one of the arches to a part which can take the thrust. The astonishing part is this: if you walk upon it, it gives under the foot almost like a board, so great is its elasticity, yet it continually withstands a thrust equal, I suppose, to many tons.—T. Jones.

[56560.]—**Eight-Inch Spark Induction Coil.**—1. If the secondary wire is wound in about 36 sections, each section being of the depth and width named in my letter of Jan. 4th, 1884, one disc of No. 24 ebonite, of good quality, will be enough in each place. 2. Yes; the spark is prevented from passing beneath the partitions, at those points where such a tendency exists, by the interposition of layers of paraffin. The melted wax may be applied with a camel's-hair brush, and, if necessary, the film may be rendered uniform by treatment with a heated iron wire, as I have before described. It is important that this insulating of the bottom of each section should be well done. The thickness of paraffin in each of the central divisions should be about ⅛in., increasing to about $\frac{3}{16}$in., as the ends are neared; and in the last few divisions at each end of the coil, the thickness may be fully ¼in. A narrow strip of wood makes a useful and simple gauge for measuring the depth of wax in any section. The employment of paraffin in this way is somewhat troublesome, and ebonite rings or washers cemented with shellac, are preferred by the principal instrument makers; but the washers are expensive, and the wax, if carefully handled, is a thoroughly efficient substitute, as was first pointed out in these columns by Mr. Brown, of Belfast, to whom we are all indebted. 3. "About 7s. per pound" was stated as the price of the uncut ebonite. The discs would be rather costly if made to order. On page 339 of Vol. XXXVII. of this journal, under the heading of "Cutting Round Holes in Tin-plate," is a sketch and description of the convenient tool which I have used in preparing my own discs. 4. A continuous-current dynamo capable of delivering at the primary terminals the precise equivalent (in E. M. F. and Current) of five Grove cells of the quart size, would, no doubt, work the coil satisfactorily; there is, however, reason to suppose that the character of the spark would be to some extent changed by this alteration of the source of power. I have had no opportunity of making the experiment.—Ernest Baugh, Haverfordwest, Pem.

[56561.]—**Electric Pen Battery.**—You say that you are using a 4-cell Fuller, and then ask, Would it be advisable to use bichromate salt? What do you charge it with if not with bichromate? You cannot expect the cells to last for ever. Perhaps you require too much from it. It should be changed as follows: Inner porous cell, zinc rod in mercury, excitant sulphuric acid 1 in 12 of water; outer carbon in solution of bichromate potash.—C. D. R.

[56562.]—**Medical Battery.**—Do you want to take the current direct from the battery, or through the medium of a coil? If through a coil, one Fuller will give you all you require.—C. D. R.

[56563.]—**Medical Coil.**—A great many books on this subject do not explain what is meant, because the writers themselves do not know, and it would puzzle them to tell you.—C. D. R.

[56563.]—**Medical Coil.**—The terms "positive and negative" as applied to currents are often confusing. A current is described as a current of positive electricity which leaves the battery by the wire connected with the carbon or copper plate; while the current which leaves the battery by the wire connected with the zinc plate is called the negative current. The former is called positive, because, in a feeble degree, its qualities are the same as the positive electricity of the glass plate in an electrical machine: the latter is called negative electricity, because it feebly resembles the electricity of rubbed sealing-wax. The zinc, though the positive plate or element, is the negative pole; and the carbon, though the negative plate, is the positive pole. When your book refers to the negative current, it will likely mean the current from the wire connected to the zinc of the battery.—Bobadil.

[56564.]—**Wooden Sink for Dark Room.**—Soak the wood of which you propose making your table or sink in melted paraffin wax; it will then resist both water and acid.—S. Bottone.

[56565.]—**Dynamo.**—1st. Yes. It takes nearly twice as much current to charge a "made" accumulator, as you will be able to get out of it. 2nd. It is not absolutely necessary to have inside cogs. See illustrations at p. 220 of this volume, for details as to mode of joining to commutator. The covering of the wire on the armature is an insulation; the hub of the driving shaft is of boxwood, or other hard wood, soaked in paraffin wax, and is also insulating. See also No. 1007 of "E. M."—S. Bottone.

[56567.]—**Wooden Sink for Dark Room.**—I should advise "Hereward" to line his sink with, say, 5lb. sheet lead, and have the angles "or joints" burnt up. This, however, he will perhaps find a difficult job to do himself, and if he will advertise his address, I will put him in the way of getting one at comparatively a small cost.—A. B. C.

[56567.]—**Dark Room.**—A table and sink to be impervious to chemicals cannot be fitted up with wood. I would recommend "Hereward" to be at the expense of a fireclay or stoneware sink highly glazed (I have bought the former for 10s.). For the table, he should look out among the plate-glass dealers for a second-hand piece the size he wants; the more scratched it is the cheaper, and bed this on plaster of Paris on his table with a very slight slope towards the sink.—B. Sc., Plymouth.

[56568.]—**Violin.**—Thomas Kennedy, born 1784, died 1870, was the son of John Kennedy, who wrought from 1730 to 1816. Davidson states that they were very prolific makers, but gives no opinion of the quality of their work. Alexander Kennedy, London, 1750, he states was a Scottish maker of good repute.—T. Lisle.

[56569.]—**Pressure in Boiler.**—This query, in its present form, is somewhat vague; but, seeing it has been addressed to me, I will answer it as far as it is practical to do so. The strength of the shell will be expressed in the following formula: $\frac{2 T \times C}{D} = B P$, T equals thickness in inches, C = 44,800lb. as strength of plate per square inch, and D = diameter of boiler in inches; then we have 2 × ·437 × 44,800 = 3,915·52, which represents the strength of a strip of the boiler-plate, 1in. wide (·437 being multiplied by two, as there are two sides of the boiler), therefore the strength of the plate divided by diameter will give pressure per square inch necessary to burst plate, and 39,155·2 divided by 85in. = 460lb. pressure to burst the shell-plate. But here we are minus an important item, viz., riveting of longitudinal seams, which "Sammy" does not give. Single riveting is only equal to 56 per cent. of solid plate, and double riveting 70 per cent. of solid plate. We will, therefore, assume it is single riveted, and multiply 460 × ·56, which gives bursting pressure as 257lb. per square inch, double riveting would give 460 × ·70 = 322lb.; these, divided by the margin of safety, will give the safe working pressure. No doubt other correspondents may answer the other queries; but I think it safest not to attempt, as I assure "Sammy" answering boiler queries without full particulars, is only misleading. If he will give following particulars, I will tell him something reliable about his boiler: Age, maker, what kind of seams in furnace, distance of first cone tube, number of cone tubes, how are ends stayed, &c.; or, better still, give me sketch of boiler. The amount of deterioration can only be assumed after an inspection.—Boswell.

[56569.]—**Pressure of Boiler.**—"Sammy" omits some important elements in his data. He does not say whether his boiler is a single or double-riveted one; nor does he say at what pressure it has been working during the last 15 years. Now, I think that a boiler that has been working during that time should be carefully examined to see if *channelling* has not taken place along the joints of the plates, and that no part of the shell or firebox has become thinned through scaling, &c. "Sammy" may take the following for what it is worth:—Cut with a hollow drill, say ¾in. in diameter, two or three discs from the shell and firebox. Of course, these discs will give the present thickness of the metal at the places from which they were taken. Now place one of the discs in a strong vice, and a sharp blow on the projecting part will determine whether the iron has become crystalline; if so, the sooner the boiler finds its way into the scrap heap the better. "Sammy," judging from his name, is doubtless a young man; if so, it is a pity that he will not spend half a dozen hours (and more is not necessary) in mastering algebraic formulæ. Now, for the boiler in question, suppose it to have single-riveted joints, the diameters of the rivets being ¾in., and the pitch, as stated, 2in., then it is clear that every inch run of the boiler shell would have an amount of metal resisting rupture equal "in plain figures" to (1in. − ⅜in.) × $\frac{7}{16}$ × 2 = $\frac{35}{64}$ inches; then taking the strength of best Bowling plate at 25 tons per square inch section, this would give for every inch run of boiler $\frac{35}{64}$ × 25 = $13\frac{43}{64}$ tons = 30,625lb. Now, as the bursting pressure on 1in. long of boiler must be equal to 30,625lb., and as the boiler is 85in. in diameter, therefore 30625 ÷ 85 = 360⅜lb. nearly = pressure on each square inch of safety-valve, when boiler would be at bursting point; but for safe working the pressure should not exceed ⅛th of this, or 60lb. Molesworth's formulæ would give about 63½lb., and for double-riveted joints the working pressure would be 80lb. per square inch.—EX-BLACKSMITH, Gorton Brook.

[56570.]—**Brazing.**—"W. J." will find it no easy matter to braze ¼-thick copper plate with gas. He will probably need a Root's blower driven by power, a 1½in. gas supply, and a blowpipe in proportion. When work of this kind is done by gas, it is usually supported on a bed of burning coke, the greater part of the heat being obtained from the coke, and the gas is used only to finish melting the spelter, and to lead the greatest heat just to the point required. The fuel value of coal-gas is so small in proportion to its bulk, that an enormous supply is required, with an efficient blower to concentrate the heat when any large work is to be done at a high temperature. If the bulk of the work is heated to dull redness with coke, a comparatively small blowpipe will then finish the brazing in first-rate style, with much less trouble and risk than if the fire is depended on alone.—T. F.

[56571.]—**Electrical.**—In decomposing a given quantity of water, two volumes of hydrogen gas are obtained for every volume of oxygen.—BOBADIL.

[56571.] — **Electrical.** — Four cells, Bunsen 1·75 volt E.M.F. ÷ by the resistance in ohms gives the amount of current in ampères. This multiplied by ·0000896 the weight of a cubic centimètre of hydrogen at 0° C. in grammes; two volumes of hydrogen are given off for one of oxygen; by weight one of hydrogen to eight of oxygen.—J. H. E. D.

[56571.]—**Electrical.**—The current given by four or five Groves or Bunsens depends on their condition and on the size and distance of the electrodes in the water. But supposing that you placed your electrodes at such a distance as to get 1 ampère of current, then in 25½ hours nearly you could decompose 9 grammes of water and produce 11 litres of hydrogen and 89 litres of oxygen.—S. BOTTONE.

[56571.]—**Electrical.**—The quantity of water decomposed by a current of one ampère per second is ·0000945 gramme = ·1764 cubic centimètre, setting free ·0000105 gramme of hydrogen, ·1176 cubic centimètre, and ·000084 gramme oxygen = ·0588cc. The volumes being at the standard pressure of 760mm., and temperature of 0° C. The internal resistance, and consequently the current from a cell, depends upon its size. Four Bunsen cells coupled up, two in series and two parallel, would probably, taking into account the counter E.M.F. and resistance of electrolyte, send about 2 ampères through the circuit, and set free about 838 cubic centimètres per hour.—EUGENE BROWN.

[56571.]—**Electrical.**—The time in which a given quantity of water will be decomposed may be calculated from this formula: $t = \frac{Q}{C \times \cdot 000094}$, where $t$ = time in seconds, $Q$ = quantity of water in grms., and $C$ = current in ampères. And the current produced by, say, five Grove cells, may be obtained from this: $C = \frac{E}{R + r}$, where $E = 5 \times 1\cdot 97$, $r = 5 \times \cdot 3$, and $R$ = resistance of voltameter. Then, having got C, you can obtain values of $t$ for any value of Q. One gramme of water, when decomposed, yields 1·24 litre of hydrogen, and ·62 litre of oxygen, or 1·86 litre of mixed gases.—X. Y. Z.

[56573.]—**Chronic Rheumatism.**—To "B.Sc., Plymouth."—If he can, I would recommend "A Many Years' Subscriber" to go to Buxton for a month, and take a course of warm bathing. If this is not available, he should take warm salt-water baths at about 100°; but what I would rely on most to effect a cure would be electricity, using the induced or Faradic current, and brushing the skin with the electric brush at the parts where the pain and cold clamminess are felt. He having been so long afflicted, will probably have tried many medicines. The only prescription I would recommend is the following: R.—Potassii iodide, 30gr.; potassæ bicarbonatis, 60gr.; tincturæ hyoscyami, 3 fl. drs.; infusi cinchonæ flavæ, ad 8 fl. oz. Mix; one sixth part three times a day. Another thing I have seen of great service in cases like his, is to keep the parts which ache and are covered with cold clamminess always covered with cotton-wool (medicated with iodine, if he can obtain it).—B.Sc., Plymouth.

[56577.]—**Soap.**—Hard soap can be made from cotton-seed oil which has not been deprived of its stearine. A great deal of the cotton-seed oil now sold has had the stearine extracted so as to make it more fluid and less liable to solidify in winter. It is largely used in America for soapmaking, both alone and in conjunction with tallow and other solid fats.—G. H. HURST, Salford.

# UNANSWERED QUERIES.

*The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.*

# QUERIES.

[56580.]—**Tricycle Pedals.**—Can any cyclist, who is a mechanic, tell me the best way to prevent my tricycle pedals from rattling? They are simply plain ones in cast iron halves, and having worn at the ends they slip sideways when working and make a very nasty clacking noise. I have tried packing them with collars made of leather boot-laces, but they soon push them aside, and I cannot tell what plan to adopt. I can easily tighten them to revolve stiffly, but it is lengthwise where the mischief occurs. Is there any plan of putting spring washers on?—C. CALVERT.

[56581.]—**Warming Room.**—Some few months ago you inserted diagrams and a description of an apparatus for warming a room with some sort of oil. Can any of your readers, who have tried the plan, tell me how it acts? I have a room without a fireplace, which I wish to make sufficiently warm to read in. It is a second-floor room, and has a chimney running through it from the room below. I should be very glad of any information as to the best way of attaining my object. Oil, if it can be managed, is perhaps the most preferable way.—T.

[56582.]—**Safety Couplings.**—Would some kind reader please give sketches of the safety couplings for railway waggons, now exhibiting at the Inventions Exhibition, with, perhaps, a short description? I am sure it will interest others as well as—A SHUNTER.

[56583.]—**Chloride of Zinc Solution.**—How can I make a solution of the above, free from lead, as nearly neutral as possible, and of 20deg. strength? To make it from pure fused chloride of zinc is too expensive: it is the solution used in the Gaiffe Clamond cells.—OLD READER.

[56584.]—**Silvering Solution.**—Will some obliging fellow reader tell me how to make the above that only requires gently rubbing on the articles of brass, German silver or copper, with a little fine whiting, to give a bright silver surface? Tome twenty years since it used to be sold by a Mr. Smith, in the narrow part of the Strand—it is an odourless and clear solution. I have tried cyanide solutions, but they do not give such good results.—OLD READER.

[56585.]—**Boring for Water.**—Will someone who knows kindly give the approximate depth and cost of boring to water, and fixing pump, &c., in red sandstone rock where water lies on the surface all the year round, at about 400 yards off and, say, 20ft. lower level? Any information will oblige one who is—ENTIRELY IGNORANT OF THE SUBJECT.

[56586.]—**Brick Setting.**—Will someone who knows kindly say the difference in cost (per 1,000) of bricks set in Portland cement and ordinary mortar?—IGNORANT.

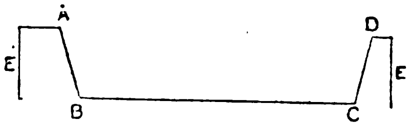
[56587.]—**Telephone System.**—I see in your issue of the 24th ult., in Replies to Queries (56361), Telephone System, there appears a diagram showing how a number of telephones can be fixed with only one wire running into an intermediate office, and there using earth (according to diagram), instead of a return wire. I should esteem it a favour if "R. F. S." would enlighten me how the current passes from A. through the intermediate office to B.—T. J.

[56588.]—**Generator Gas Explosive Force.**—Will anyone please send results given by gas-engine when generator gas (such as gasoline, benzoline, &c.) was used? Particulars required are, (1) Length of stroke and diameter of cylinder? (2) Proportion of ordinary air mixed with the gas before ignition? (3) If a compression engine, number of pounds pressure before ignition? (4) Maximum pressure of explosion, and (5) mean average pressure? These results will no doubt interest many in the gas-engine world besides—E. C.

[56589.]—**Cost of Cottage.**—I am thinking of joining a building society, but have been persuaded to save money enough to buy a piece of building land before doing so. Would someone kindly tell me what I should be likely to have to pay a building society to build me a cottage of four rooms about 12ft. square and 9ft. high, with small washhouse at back about 8ft. square, closet, well, &c.; bricks are in the neighbourhood, no drains to lay or gas to fit, being in the country?—O.

[56590.]—**Soap for Hard Water**—Wanted a soap or preparation able to easily produce a good lather in very hard water, from a limestone source? Ordinary soap is almost useless for ablution.—M. C. H.

[56591.]—**Lee Boards to Boats.**—I have a boat 15ft. long, flat bottomed and double ended; I want to



fit lee boards on each side. Will any one tell me what the dimensions of each should be? A, B, C, D, represent a section of the boat, E E position of lee boards.—O. A.

[56592.]—**Electro-Motor.**—I have made a small electro-motor, in which the armature (a plain bar of iron) revolves above the pole of the electro magnet; but when the armature gets at right angles to the poles of the magnet, it stops. Would it be better if, instead of a plain bar of iron, I had one in the form of a cross? If so, how many contacts should I have on the spindle; and also, which is the best way to connect up so as to get the greatest power out of the electro-magnet?—M

[56593.]—**Roofing.**—I shall be much obliged if some one will tell me how to calculate the number of slates (say slates 20in. by 10in.) required to cover a roof of given dimensions; also, what will be the average weight on each square foot of surface when ordinary N. Wales slates of that size are used?—RAFTER.

[56594.]—**Lime-Light.**—Would "Excelsior," reply 56045, kindly explain how limelight can be produced for lantern purposes "at less cost than the four-wick refulgent lamp," by bringing "a small amount of ingenuity and patience to bear upon it"? I would be glad to apply my entire stock of both to secure so desirable an end; and have no doubt the lime-light would be far more extensively used if brought within the means of lanternists whose purses are not very plethoric.—TYRO.

[56595.]—**Spectroscope.**—I shall be very thankful to anybody who will tell me how to make "a spectroscope out of paper tubes, cheap lenses, a few pieces of glass, and a little bisulphide of carbon at a total cost of 5s., which will divide the D sodium line," see p. 182, present volume of "E.M."? My spectroscope cost six times the sum stated, and will not divide the D line. An efficient spectroscope is one of the most engaging instruments a person of scientific mind can have; but the high prices of good instruments too often prevent their use, at least by English or Irish mechanics.—E. B. FENNESSY.

[56596.]—**Leaky Dark Slide.**—I have a double dark slide which lets light in through a crack in the sliding shutter; the slide is otherwise perfect. What is the best way to fill up the crack to prevent it leaking?—A. R. F.

[56597.]—**New Midland Engines.**—Will someone kindly tell me in what number of the *Engineer* illustrations of the new Midland engines (No. 1675 class) appeared?—IRON HORSE.

[56598.]—**M. S. and L. Single Engines.**—Will W. H. Thurlow kindly give dimensions and particulars respecting the M. S. and L. 7ft. 6in. single engines, as he kindly offered? Also, how many have been built of them?—IRON HORSE.

[56599.]—**Photographic Plates.**—Have any of our amateur photographers used the Archer dry plates, as I have, and cannot obtain good negatives at all? I have tried long and short exposures, besides weak and strong developers. Hints as to the above will oblige—PERSEVERING.

[56600.]—**Focal Distances of Images.**—Will one of our optical contributors oblige by giving the rule, not by algebra, for calculating the focal distances of concave and convex mirrors, also for double convex lenses? Supposing a lamp is placed 20ft. from a concave mirror of 3ft. focal length, I want to find the image.—A. H. K.

[56601.]—**Building Construction.**—I am very desirous to pass the elementary stage of the Government exam. on the above subject. Can the subject be learnt well enough by private study? Are any other books of use besides the first vol. of Rivington, or are any diagrams published that would be of assistance? Any information regarding a course of study would be greatly esteemed by—A STUDENT.

[56602.]—**Cassegrain Telescope.**—To DR. ROYSTON PIGGOT.—I feel greatly interested in your articles on the Cassegrain; they are invaluable, and I hope will be continued. In the No. 3 paper, you speak of the convex being of the exact size of the hole in great mirror. Does this apply to all the convexes of different focus? If so, then the shorter focus will be of larger diameter than the cone of rays from the large mirror, will they not? Can a Cassegrain be constructed of 26in. aperture with as low a power as 30 diameters? If so, will you please give the foci of large and small mirrors? I care not how short it is, the telescope being designed for comet work. —CASS.

[56603.]—**Spinning Wheel—Loom.**—Would some one tell me how to make a spinning wheel, and also how to spin with it? Could any of the readers of the "E.M." tell me how to make and work a loom?—R. MECHANIC.

[56604.]—**Differential Equation.**—Will some one oblige me by giving a solution to the equation $\frac{d^2y}{dx^2} - a\frac{dy}{dz} = 0$, or in what book a solution may be found?—H. H.

[56605.]—**Waggon Wheels.**—I have two waggons, the frame of one being (inside) 6ft., and the other, 5ft. 11in. I am breaking up the latter. Can I use the wheels under the former?—i.e., will the wheels that come from under the 5ft. 11in. waggon, answer for running under the 6ft. frame, and what alterations will be necessary to enable me to do this?—COAL MERCHANT.

[56606.]—**Ink for Rubber Stamps.**—I wish to make some preservative ink for use with a rubber stamp, and should be much obliged for directions for making it in small quantities, and red or blue in colour.—Faber Fabrum Adjuvet.

[56607.]—**Lighting with Battery.**—Will Mr. Bottone, or some other kind correspondent, please answer the following? I have four cells of a bichromate battery, plates, 5in. by 8in., a zinc in porous pot, and two carbons to each cell. I wish to be able to light a small incandescent lamp with this. What solutions ought I to use to get the best result, and what sort of lamp should be employed?—Faber Fabrum Adjuvet.

[56608.]—**Legal.**—On taking over a house from a present occupier, could any kind reader inform me at what time of the coming quarter day I am legally allowed to take possession? What I require is, whether 12 o'clock at noon, or 12 o'clock at night?—A Tenant.

[56609.]—**Analysis of Asbestos.**—What is the composition of asbestos? Do different kinds differ in analysis? Where is it found? How is it the Italian asbestos, usually sold at 4s. a pound, cannot be had now? Would Mr. Allen or Colonel Ross kindly say if it would be possible for anyone possessing but a slight knowledge of chemistry, to make a reliable analysis of such a material, starting with the assumption of entire ignorance of the chemical composition of such material?—Murano.

[56610.]—**Alloy for Watch Bearings.**—In the *Mechanics' Magazine*, for Nov. 13th, 1830, is an account of an alloy made by Sir (then Mr.) John Bennett, for watch pivot holes. It is gold, 3dwt.; silver, 1dwt. 20gr.; copper, 8dwt. 20gr., and palladium, 1dwt.; in colour, reddish brown, and takes a good polish, and is not affected by nitric acid. It fuses below temperature required for gold; it is nearly as hard as wrought iron, but could be drawn into wire; rather brittle; fracture finer than steel. The *M.M.* editor said of it "it seems to us that there can be but little doubt of the general adoption of this alloy, in preference to any substance which has yet been employed for pivot holes." Diamonds and rubies are shown in the same article to be "perfectly awful" things to put in a watch, as they grind the end of the pivot away. Are not the latter now used in watches, in preference to anything else? Had the alloy in question any real merit over phosphor bronze or Babbitt's metal, and is it ever used now?—Murano.

[56611.]—**Junket.**—Will any reader inform me how to make a junket, such as eaten in Devonshire?—Akreophagist.

[56612.]—**Copper Band.**—Will some kind reader oblige by informing me how the two halves of a copper band are worked up, so that the seams are at the sides, and what tools are used for hammering on? A sketch of band would oblige.—Plate Worker.

[56613.]—**Apparent Enlargement of Celestial Objects.**—To "A Fellow of the Royal Astronomical Society."—May I ask where the pamphlet by M. Paul Stroobant, on "The Apparent Enlargement of Celestial Objects, as they Approach the Horizon" is published, and by whom?—and if the above is not the title, what is? It is spoken of in letter 23918, on page 30 of this volume.—James W. Fraser.

[56614.]—**Trespass.**—Will any of our legal friends kindly say if a trespass is committed by walking in estates in the pursuit of entomology, botany, and microscopy? I have seen this question repeatedly asked in various papers; but have never noticed a satisfactory reply, with reference to penalties incurred, &c.—Ento.

[56615.]—**Air Pressure at High Temperatures.**—I wish to find what the pressure of, say, a cubic foot of air would be, if heated to different temperatures, from 100° Fahr., to 1,000° Fahr. (or Centigrade equivalents). Air having been confined hermetically at any temperature, though 60° Fahr. or Zero Fahr. or Centigrade would be most convenient. I am aware that the confining substance would include more at a high temperature, than the cubic foot of a lower temperature, but that would not affect my purpose; expansion of the internal capacity could be allowed for. Is there any guage for ascertaining hot air pressure?—how do hot air engines manage?—Murano.

[56616.]—**Greek.**—Will some Greek scholar kindly say how the diphthong ωυ is to be pronounced in Greek words as εωυτου for εαυτου, and ωυτος for ο αυτος in Herodotus, and Ionic Greek?—L. C.

[56617.]—**Stained Skin from Wearing Black Stockings.**—Will someone tell me of some soap or other means of removing the objectionable stain? Ordinary soap and hot water avail but little; please help.—Bunthorne's Bride.

[56618.]—**Salicylic Acid.**—I bought some salicylic acid. It is fine and feathery in appearance, and always crystallises in fine needles after solution, it is very sparingly soluble in water. "Haydon's Scientific Dic." says, sal. ac. is soluble in water, and crystallises in large four-sided prisms. Can anyone show why there is such a difference in what I read of, and what I buy?—Rob Caus.

[56619.]—**Oxy-hydrogen Blowpipe.—Steel Furnace.**—Could I use this for melting experimental lots of metal, say half a pound (or double) of iron?—if so, how should one be made? A sketch would no doubt be valued by others than myself. Would an oxy-hydrogen blowpipe be expensive to use? Any information welcome. How also could I construct a convenient furnace to melt 1cwt. of steel? How should I produce the blast, and what materials should I use, and what sort of crucible would be required only for experiments?—Murano.

[56620.]—**Steam Carriage.**—I am desirous of having a small steam carriage for use instead of a horse, on the public road; but am told the restrictions under which they are allowed to run, are practically prohibitive. I shall be very much obliged for any information on the subject? Also what sort of machine is best to have, and the probable cost of one strong enough to carry two people up a stiff hill? Of course it must be silent, and show neither smoke nor steam, and be as little like a steam-engine as possible. I have thought it should have rubber tires, and the general outline something after the style of a brougham.—Steam Roadster.

[56621.]—**Electric Light for the Optical Lantern.**—Would Mr. Wright, or any of "Ours," who have had practical experience, kindly advise as to the best arrangement for using an arc light of from 2,000 to 3,000 candle-power, as I have been experimenting with the same, and find the heat so great as to crack the transparency or negative? Would an alum cell placed between the light and condenser be best for cutting off the heat rays? A rough sketch of best arrangement would be esteemed.—Arc Light.

[56622.]—**Lightning Conductors.**—What precautions are necessary, or the things to be guarded against, in erecting a lightning conductor on a building? Is it best to insulate the conductor with glass, or to allow the conductor to rest in contact with the iron supports or holdfasts? What are the best forms to use—the tape or the solid round wire, or the round hollow tube form? What area will a conductor 80ft. high protect? Assuming that a conductor protects a circular area around its base, what would be the radius of the circle in this base, when its height from the ground is 80ft.?—R. S. B. H. B.

[56623.]—**Polishing Steel.**—I have a lathe and a 4in. by 1in. emery wheel; but when I grind flat steel it comes off in waves, and requires draw-filing and much labour to flatten it again. Can someone kindly explain how to grind a flat surface, say 12in. by 1in.? Also what sort of polishing wheel and powder I should use, to follow the emery wheel, in order to produce a fine even polish on such surfaces?—Acier.

[56624.]—**Newmarket Direct Railway.**—Can any reader give me any information respecting the railway from Chesterford to near Six Mile Bottom? The earthworks seem to be complete, and some bridges are built. When was it started, and why given up?—East Anglian.

[56625.]—**Steam.**—Will some kind reader show the working of the following problems:—A pound of steam is led into 11lb. of ice-cold water, what is the temperature of the mixture? Also ½lb. of steam is led into 12lb. of water at 20° C.—what is the temperature of the mixture?—Hot Water.

[56626.]—**Fermentation in Horehound and Hop Beers.**—Would any of our kind readers help me out of my difficulty? Being in a small way of making horehound and hop beers, I find that in, say, three or four weeks after bottling there is a kind of mildew on some of the bottles, and others with a dark brown substance adhering to bottle neck, which makes it look very unpleasant to the eye, and unpleasant to drink. Anyone showing how to remedy the above, would confer a great boon on a—Poor Brewer.

[56627.]—**Thoma Microtome.**—I should be obliged if any reader will give a description of this microtome which is said in your Scientific News column, of May 1st, to be able to cut sections of 12,500 to the inch?—R.G. L.

[56628.]—**Heliograph.**—I should feel obliged if any of "ours" would explain the mode of working the heliograph? The point I find a difficulty about is to understand how the flash of reflected sunlight is thrown with certainty upon a spot miles away from the operator. I should also like to know if the signals are dashes and dots as in telegraphy?—Magister Artibus.

[56629.]—**Hydraulic Ram.**—Will any of our kind practical mechanics tell me how I can make a small hydraulic ram? I want it to force a jet of water 5 or 6ft. high. A rough sketch, with dimensions, will greatly oblige—A. L.

[56630.]—**Brake Failures.**—What number of actual failures, under Class 2, are recorded in the Return, and is any information given as to the number of times any brake has been applied on any one day?—Brake.

[56631.]—**Photographic.**—To Mr. Lancaster or Others.—Can I use with the ¼-plate camera, Le Meritoire, one of Dallmeyer's ½-plate W.A. lens, also, will the camera require any alteration? I should like to be able to use either lens if possible, and should be glad to hear of a simple and effective method of fitting the lens.—C. F. G.

[56632.]—**Water Line.**—In draughting the hull of a vessel of 3,000 tons, or, say the *Himalaya* for instance, which is about 3,440, how shall I calculate for placing the water line? Should be glad if any kind reader can inform me?—Verax.

[56633.]—**Hay and Corn.**—Would some kind and able reader of "Ours," acquainted with the hay and corn business, kindly give me a few hints in the same? How to tell the weight of a hay rick by measurement. I shall be retailing it in small quantities? Any information will thankfully be received by—Perseverance.

[56634.]—**Piccolo.**—Will any reader be kind enough to give me particulars relating to a Boehm piccolo? 1st, The length of each part of it; 2nd, the size and position of every hole; 3rd, the width of bore throughout?—S. R. P.

[56635.]—**Clamp Burning.**—Will some of our London readers help me with burning clamps? Having a lot of bricks made and clay mixed on the above system, the man slipped off, and I am left to do the best I can? Should breeze or cinders be put in the scintles underneath the three layers or strata? and when they are burning should the clamp be plastered at the sides and earthed in tight on the top as it burns?—One in a Fix.

[56636.]—**Australia.**—What are the prospects for electrical engineer, telegraph, telephone, or electric light going out from this country to Melbourne? What things are dear there, and what should one take—tools, clothes, books, are they dearer than here? Any advice will oblige—A.

[56637.]—**Electric Lighting by Batteries.**—I intend lighting up a house with two or three Swan 10-c.p. lamps of 10 volts each. Would any of our readers tell me how many cells of the Daniell or Bunsen form I should require to keep the lamps burning brightly for four or five hours per night, and what kind of solution to charge them with, and how many volts will a quart Daniell give off? I have five cells of the Daniell form which, when not in use I remove zincs and coppers, and when I leave them for a day or two the tops of the porous pots are covered with a kind of a metallic salt. Will any of "Ours" tell me how to remedy this?—Young Beginner.

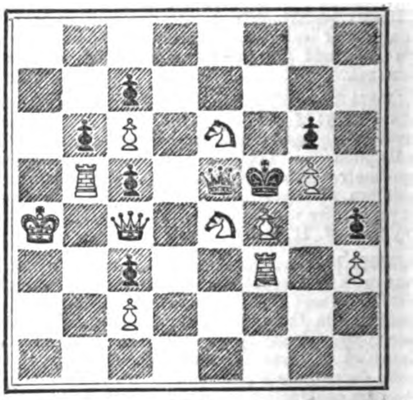
[56638.]—**Cleaning Glass.**—Would someone inform me, through the medium of your valuable paper, the best thing to clean glass negatives, windows, &c.? I have some shop windows, and have so far been using whiting and now and again water; but somehow I cannot clean them without leaving them, more or less, cloudy and dull looking. I think somehow there must be some composition or something that I could buy, that would make them look bright after cleaning. I was told some time ago that photographers used something for cleaning their negatives called clouding; have asked for it in several places but cannot procure it; perhaps I am wrong in the name.—W. J. Blakemore.

## CHESS.

All Communications for this department must be addressed to J. Pierce, Langley House, Dorking.

### PROBLEM DCCCCXXXIX.—By Idem.

*Black.*



*White.* [11+8

White to play and mate in two moves.

Solution to 937.

| *White.* | *Black.* |
|---|---|
| 1. R-Q 4 | 1. Anything. |
| 3. Q or R mates. | |

(Five variations.)

### NOTICES TO CORRESPONDENTS.

Correct solutions to 936 by Exon (a real beauty), A. S. Olver, V. S. Pochin (Black too confined, consequently very easy), G. J. Slater, T. L. Robins, and F. O'N. H.

To 937, by A. W. Orr, Rev. W. Anderson (Old Romney), F. A. Vincent, A. A. E. Leoluse, F. B. Webb, G. J. Stingfellow, R. A. Bennett, E. Stanley Follwell (neat, pretty, and easy), A. S. Olver (very good), V. S. Pochin, G. J. Slater, T. L. Robins. That by Exon is wrong, as 1. K-B 5.

Correct solutions to 938 by Streetgate (first move a little puzzling) and E. S.

Raymond.—We are sorry you are unable to go on with the competition.

G. R. W.—We do not know to what problem you refer. Please send the number with the two solutions.

J. Russell.—Thanks for game.

**Resistance on Railway Curves.**—What the precise effect is of a difference of gauge on curve resistance—and in fact, of all other modifying conditions—is still a matter of doubt, but theory and experience combine to indicate that, all other conditions remaining the same, the curve resistance is directly as $\sqrt{\text{gauge}^2 + \text{length of wheel-base}^2}$; from which it follows that a reduction of either the gauge or length of wheel-base alone will not materially modify the resistance; but if both be reduced together, so that the rectangle of the wheel base remains always "similar," the curve resistance may vary very nearly as the gauge. Approximately this condition obtains with standard and narrow-gauge rolling stock as now designed, but whether or not practical conditions make it necessary or expedient that it should be so, so that it is a legitimate, instead of merely accidental, advantage of the narrow-gauge rolling stock, it is profitless to inquire, because the *Railroad Gazette* says the direct loss of power and wear and tear from curve resistance is comparatively a trifling matter, and any assumed difference in hauling capacity—which is not often a very serious consideration, however, for light traffic roads—may be easily compensated for by a slight increase in the rate of compensation for curvature—an increase which will have far too trifling an effect on the average gradient to make any measurable difference in the location or profile.

## ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

### HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, May 13th, and unacknowledged elsewhere :—

J. ROBERTS.—W. F. Stanley.—W. H. B. and Co.—F. W. Greene.—Gilford Mills Reading Room.—J. Gillott and Son.—Pfeil and Co.—H. Murphy.—Sanitas Co.—J. and H. Grace.—Camera.—T. H. L.—Sammy.—Sand Rat.—An English Mechanic.—Hemisus.—Rob. Crusoe.—B.—Edward M. Nelson.—S. Stokes.—A Fellow of the Royal Astronomical Society.—An Amateur.—W. Hardie.—Upholsterer.—S. Beeching.—W. D.—Telegraphist.—Theo.—Quantum Libet.—Millwright Apprentice.—Albert Turner.

A. DOBER. (For methods of treating sciatica, see pp. 412, 436, Vol. XXXVI.; for syrup of phosphates, you must apply to the maker; but you will find something about it under the head of Chemical Food in back numbers. See p. 73, Vol. XXXIV., for instance.)—OLD SUBSCRIBER. (They must be bleached either by careful washing over with weak solution of chloride of lime or peroxide of hydrogen, or by exposing to the fumes of burning sulphur.)—MECHANIC. (Rather doubtful if ringworm. You should consult a medical man, who will be in a position to form an opinion when he sees them.)—A. G., Putney. (Geometry and mathematics, mechanics, electricity, steam, heat, &c. We cannot say about "taking you for a time without a premium." You will have to enter as an apprentice in the ordinary way, or as a "gentleman apprentice," and in the latter case a premium will certainly be asked.)—S. GREENWOOD. (We have frequently stated that entrance is obtained by ballot on the recommendation of a certain number of Fellows; but you can obtain all information on application to the secretaries of the societies.)—AKENAWAKA. (Possibly the portions specked were not thoroughly covered. 2. Varnish black or japan black. See advertisements of dealers in such materials.)—S. T. KLEIN. (If the query was received it was noticed in some way. We do not remember the book mentioned; but if there is a work under that title you might find it in the British Museum Library.)—TRITON. (We do not know that it has reached a second edition, but the English publishers, Messrs. Macmillan, could probably tell you. The query is scarcely of sufficient interest to occupy space in our columns.)—C. M. HOWARD. (We know of no work of the kind; but as you will see by the advertisement columns, you can now procure the membrane telephones. All the information needed is to be found in the back volumes.)—GRAPHO. (Messrs. Trübner, Ludgate-hill, supply any American paper to subscribers—not single copies. We dot know where the photographs can be obtained.)—R. S. T. (Scarcely worth while repeating the statement. The Britannia Company's stand is at the West-end of the Middle Court. 2. No, we should call them more or less impure alumina.)—J. G. HODGSON. (G. Bower, St. Neot's, Huntingdonshire.)—AMATEUR. (See the indices; the stopping depends on the kind of wood used, but as a rule, it is "size" after the staining. See p. 371, Vol. XXXVIII.; pp. 16, 64, 186, Vol. XXXVII.)—APPRENTICE. (Glatton's letters on the Slide-Valve Diagram were in Nos. 995, 999, 1039, 1041.)—J. STOKER. (See Hints No. 5. It is a Railway Sub-office in Somersetshire, and appears as such in the Postal Guide.)—T. MAC. (Black's "Treatise on Brewing," Longmans; that is the work recommended by the correspondent named. Herbert's "Art of Brewing," published by the author at Burton-on-Trent, is a useful work. There is also a treatise by Levesque, and another by Tizard.)—W. HOWELL. (What engine do you mean? Surely the dimensions have been given.)—F. G. T. (See Hints No. 4. Asbestos can be obtained, as a rule, of those who sell gas-stoves.)—EDWIN HOLMES. (There is no doubt the man is a rascal. We do our best to weed out swindlers; but from time to time they evade us, and by change of name and address, succeed in again defrauding readers. We are glad you had sufficient sense not to be caught. Readers should in no case part with money to unknown correspondents before they get their goods, and should in all cases remit by P.O.O. made payable ten days after date, and then, if the goods do not arrive, stop payment of the order.)—AN ENGLISH MECHANIC. (No good is done by detailing the defects of the brakes, and then asserting in general terms that a brake exists which avoids them all, and that if Mr. Stretton likes you can give particulars. You can do this privately if you like—he appends his address to many of his letters; but it is probable he knows it already; or you can send us a sketch and description, and if there is really any good in it, we will publish them.)—E. T. B. (Your only course is to patent the invention, and then seek the aid of some capitalist through our advertisement columns or those of some other newspaper.)—G. R. POSTLETHWAITE. (In type.)

## USEFUL AND SCIENTIFIC NOTES.

**Shrinkage of Paper.**—At a meeting of the North of England Institute of Mining and mechanical Engineers, a paper "On the Shrinkage of Paper," was read by Mr. C. C. Leach. It contained an account of experiments upon the shrinkage of different kinds of drawing paper made under various conditions, and shows how very capricious is the behaviour of this material under the ordinary conditions to which it is subjected as a medium of plotting and mapping. The mode employed by the writer in showing the variations was to mark off accurately upon the paper experimented upon distances from a scale representing 120 chains, a wooden scale being chosen as much less liable to alter in length than an ivory one. The following are the conclusions arrived at by the writer:—That machine-made papers vary less, and less unequally, than hand-made sheets. That mounted paper varies much more than unmounted. That new paper, and especially new mounted paper, varies more, and more unequally, than older, and older mounted plans. That papers, mounted or not, and irrespective of age, continually vary. No two plans vary alike. Daily and yearly variations are similar for all plans. Making a scale on the paper, as an accurate standard of measurement, is all but useless, as different parts of the same plan vary in size so differently at most times. The very uneven and changing alterations in the sizes of plans, which twist the base lines and otherwise affect their general accuracy, are of sufficient importance for the extent to be ascertained, and, if practicable, for some means to be devised for obviating these variations.

THE contract for the supply of telegraph instruments and batteries for the next twelve months to the Manchester, Sheffield and Lincolnshire Railway Company, has been secured by Messrs. Blakey, Emmott and Co., of the Northern Telegraph Works, Halifax. This firm have just issued an illustrated catalogue in three parts, Part I. containing list of railway-signal apparatus, resistance coils, and general testing apparatus; Part II. electric bells, &c., and part III. electric-light machinery.

**Every Workman connected with the Building** Trades requiring a Situation should advertise in "THE BUILDING NEWS," published every FRIDAY, price Fourpence, at 332, Strand, London, W.C.

"THE BUILDING NEWS" is the Principal Journal representing Architects and Builders, and has the largest circulation of any Professional Journal in the kingdom.

Every Workman should insist on seeing "THE BUILDING NEWS" every week at his Club or Coffee House. He will find more "Lists of Tenders" for new work in it every week than in any similar paper, and can thus judge where work is likely to be had. He is also specially invited to make use of "Intercommunication" if he wants to know anything about his trade; to write to the Editor if he has any suggestions to make, and to advertise in the paper when he wants work.

The charge for Advertisements for Situations is On Shilling for Twenty-four Words, and Sixpence for every Eight Words after

## TERMS OF SUBSCRIPTION.

### PAYABLE IN ADVANCE.

6s. 6d. for Six Months and 11s. for Twelve Months, Post-free to any part of the United Kingdom. For the United States, 13s., or 3 dols. 26c. gold; to France or Belgium, 13s., or 16f. 50c.; to India (via Brindisi), 15s. 2d.; to New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-office order. Back numbers cannot be sent out of the United Kingdom by the ordinary newspaper post, but must be remitted for at the rate of 1d. each to cover extra postage.

Messrs. JAMES W. QUEEN and Co., of 924, Chestnut-street, Philadelphia, are authorised to receive subscriptions for the United States for the ENGLISH MECHANIC, at the rate of 3 dols. 26c. gold, or Thirteen Shillings per annum, post-free. The copies will be forwarded direct by mail from the publishing office in London. All subscriptions will commence with the number first issued after the receipt of the subscription. If back numbers are required to complete volumes, they must be paid for at the rate of 1d. each copy, to cover extra postage.

Vols. IV., VII., XXVI., XXVIII., XXX., XXXII., XXXIII XXXIV., XXXV., XXXVI., XXXVII., XXXVIII., XXXIX. bound in cloth, 7s. each. Post free, 7s. 9d.
Vol. XL. now ready, price 7s. Post free 7s. 9d.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each, post-free from the office (except index numbers, which are 3d. each, or post-free 3½d.)

Indexes for Vols. I., VI., VII., VIII., and IX., 2d. each. Post free 2½d. each. Indexes to Vol. XI. and to subsequent vols., 3d. each, or post free, 3½d. Cases for binding, 1s. 6d. each.

## NOTICE TO SUBSCRIBERS.

Subscribers receiving their copies direct from the office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary, if it is desired to continue the Subscription.

**Epps's Cocoa.**—Grateful and Comforting:—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided our breakfast tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—*Civil Service Gazette.*—Made simply with boiling water or milk. Sold only in packets, labelled—"JAMES EPPS and CO., Homœopathic Chemists London."—Also makers of Epps's Chocolate Essence

## CHARGES FOR ADVERTISING.

| | s. | d. |
|---|---|---|
| Thirty Words | 2 | 6 |
| Every additional eight words | 0 | 6 |

Front Page Advertisements Five Shillings for the first 40 words, afterwards 3d. per line. Paragraph Advertisements One Shilling per line. No front page or paragraph advertisement inserted for less than Five Shillings. Reduced terms for series of more than 6 insertions may be ascertained on application to the Publisher.

ADVERTISEMENTS in EXCHANGE COLUMN—for

| | s. | d. |
|---|---|---|
| Twenty-four words | 0 | 3 |
| For every succeeding Eight words | 0 | 3 |

ADVERTISEMENTS in the SIXPENNY SALE COLUMN.

| | s. | d. |
|---|---|---|
| Sixteen words | 0 | 6 |
| For every succeeding Eight Words | 0 | 6 |

*** It must be borne in mind that no Displayed advertisements can appear in the "Sixpenny Sale Column." All advertisements must be prepaid; no reduction is made on repeated insertions; and in cases where the amount sent exceeds One Shilling, the publisher would be grateful if a P.O.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.O's.

The address is included as part of the advertisement, and charged for.

Advertisements must reach the office by 1 p.m. on Wednesday to insure insertion in the following Friday's number.

**Holloway's Pills** are particularly recommended to persons of studious and sedentary habits, who gradually fall into a nervous and irritable state unless some such alterative and restorative be occasionally taken. Nausea, headache, giddiness, and mental apathy quickly yield to them, and they regulate alike capricious appetites and all bowel irregularity.

## OUR EXCHANGE COLUMN.

*The charge for Exchange Notices is 3d. for the first 24 words and 3d. for every succeeding 8 words.*

**Good Value Offered** (cash or instruments) for all kinds of sound or repairable Scientific Appliances.—CAPLATZI, Science Depot, Chenies-street, near British Museum. Established 1862.

Wanted, set **Dynamo Castings**, about 150 c.-p., in exchange for Pint Bunsen Cells.—E. THORNTON, Hindpool-road, Barrow-in-Furness.

"**Flute Music**," in exchange for C. Nicholson's Pot-pourri and Weidner's Portuguese Air, flute and piano. One or both.—Particulars, J. DICKSON, Atlantic Avenue, Belfast.

Double **Dark Slides** (2), quarter-plate, nearly new Exchange turning tools, or offers.—J. T. SKINNER, Turner, Chase-road, Southgate, London, N.

Wanted, **52in. Club**, Humber, or Invincible BICYCLE in exchange for Lathe by Milnes.—F. UNDERWOOD, Beverley.

What offers in exchange for **Orguinette**, almost new, cost £2 15s.; and round Brass Clock, cost 10s. 6d.?—HARDING, 196, Holloway-road.

Good **Stereoscope**, cost about 30s., with slides. Will exchange for Opera Glasses, Microscope, &c.—HARDING, 196, Holloway.

Any offers for Dolly Varden **Sewing Machine**, a few parts missing; also set of 12 Bells on rod, best bell metal?—HARDING, 196, Holloway-road.

**Tricycle** wanted; can repair same. Exchange Singer's Sewing Machine, new, cost 80s.; "Cyclopædia Machinery," 50s.; 100 ENGLISH MECHANICS, 56 "Engineering Review."—T. PALMER, Keston, Kent.

"**English Mechanic**," Vols. XXXIV., XXXV., XXXVIII., XXXIX., XL., unbound, complete. Exchange.—H. COLLINS, Canterbury.

**Bichromate Batteries**, 20 cells, with filtering arrangements. Price £1.—S. COOPER, Brookfield, Heaton, Bolton.

Wanted, "**Knowledge**," unbound, to date, in exexchange for "Popular Educator," 6 vols., cloth, or 7 vols, Charles Dickens.—T. B. B., St. Chad's Parsonage, Derby.

**Tricycle Wheels**, Bicycle Wheels, and Fittings Wonderfully cheap. Also for Safety Bicycles.—W. Gwinnett and Co., Wolverhampton.

**Lathes**, Lathes. Cheapest and best. List, 2 stamps Nothing equal at price.—Robinson, Somerset-road, Sheffield.

100 **Foreign Stamps**, including Brunswick, Ceylon Tasmania, Egypt, Greece, Luxemburg, free 7d.—Hely, Foley street, London.

Patent Spiral Grip **Letter Racks**. "An invaluable invention." Parcels post, 1s. 3d.—Iles, Highgate-street, Birmingham.

Pumphrey's **Pocket Tripod**, for cyclists, professional and amateur photographers. Perfectly rigid. May be had on approval. Illustrations and testimonials free.—Pumphrey, Stanhope-street, Birmingham.

The **Camera and Lantern**, with three instantaneous photographs; gives full instructions in their production; 6d. post.

**Camera and Lantern Apparatus**, dispenses with multiplicity of slides, 36 plates carried, changed anywhere.—Pumphrey, Birmingham.

Pumphrey's **Hydrostatic Shutter** gives instantaneous or timed exposures; 10s. Illustrations post free.—Pumphrey, Stanhope-street, Birmingham.

Col. Ross's Patent **Filter Pipe**, price 1s. 6d., post free 1s. 8d.—G. Deal, 7, Holborn Viaduct, London, E.C.

The **Pipe of all Pipes**. Price 1s. 6d., post free, 1s. 8d.—See above.

Patronised by the **Prince of Wales**. Price 1s. 6d., post free 1s. 8d., at above address.

**Recommended** by the English Mechanic. Price 1s. 6d., post free 1s. 8d.—G. Deal, 7, Holborn Viaduct, London, E.C.

A **Sure Cure** for Dyspepsia and Heartburn. Col. Ross's Patent Filter Pipe.—See above.

**Selling by Thousands.**—Try one if you have not seen it. Price 1s. 6d., post free 1s. 8d.—G. Deal, 7, Holborn Viaduct, E.C.

Smoked all the World ever.—**Col. Ross's Patent** Filter Pipe. Price 1s. 6d., post free 1s. 8d.—See above.

**Beware of Imitations**, useless and fraudulent. We sell only Col. Ross's Patent. Price 1s. 6d., post free, 1s. 8d.—G. Deal, 7, Holborn Viaduct, London, E.C.

**Col. Ross's Patent Filter Pipe.**—Look out for it at the "Inventories" Exhibition; meanwhile buy one of us.—G. Deal, 7, Holborn Viaduct, London, E.C.

**The Kinetic Engineering Company**, 36 and 37, Brooke-street, Holborn, London. Circulars and list post free

**Dynamo Wire**, 1s. 2d. per lb. Line Wire, 29s. 6d per mile. Pushes, 4s. per dozen.—Kinetic Company.

**Leclanche Cells**, best. No. 1, 16s.; No. 2, 19s.; No. 3, 22s. 6d. per dozen.—Kinetic Company.

**Electric Bells.**—Best quality, workmanship, appearance and value in market, 40s. per dozen.—Kinetic Engineering Company.

**Maiche Patent Battery.**—Best yet produced. Circulars and Scientific Reports post free.—Kinetic Engineering Company.

**Electrical Supplies**. Wholesale only.—Kinetic Engineering Company, 36 and 37, Brooke-street, Holborn, London, E.C.

**Devonshire Cream**, delicious, by improved centrifugal process. Parcels Post, lb., 1s. 6d.—G. Bull, Manor Farm, Martock, Somerset.

**Planing**, not exceeding 10in. by 10in. by 8in.—B. W. Clegg, 18, Belinda-street, Hunslet, Leeds.

For **Model Work** (wheel-cutting in brass only); also Boring, Turning, and Screw-Cutting.—Clegg, as above.

**Piles cured at once** by using Dr. Farquharson's Remedy. Free by post for 2s.—2, Standish-street, Burnley.

**Electric Bell**, Battery, Push, and 30 yards of Wire, carriage free, 9s.—A. Shafto, Urmston, Manchester.

**Electric Bell**, 4s. Leclanché Battery, 2s. Bichromate, 3s. Coil, 6s. Wire ½d. per yard.—As above.

All **Parts and Fittings** of the above cheap, with instructions for amateurs to construct.—As above.

3¼in. Wray **Telescope**, excellent definition, good as new, objects and full particulars.—T. Clapham, Austwick Hall, Lancaster.

**Copying Ink Pencil**, new patent indelible, Cam action; best ever introduced. Warranted to wear well. Post free 7 stamps.—Purkess, 37, Huntingdon-street, Kingsland.

Profitable pursuits in Leisure Hours!—**Blowpipe** and Lamp combined, handy little instrument for blowing joints; every requisite; book of plain instructions; in box, free 2s. 6d.

**Soldering Apparatus.**—Soldering Iron, Heating Lamp, Solder, every requisite, book of instructions, packed in box, 3s. 9d. free.—J. Irving, 14, Queen-street, Gravesend.

**Boiled Oil** quick dryer, something new, full working instructions, 5s.—J. Murray, 6, Hamlet-street, Bootle, Liverpool.

**Desmometer**, giving at sight weights of rivets and bolts of any size and length. Useful formulæ, 1s. 6d.—W. Stephen, 76, DeGrey-street, Newcastle-on-Tyne.

**Oxygen Gas**, compressed in cylinders, handiest and safest for limelight.—Clarkson, Compressed Gas Chemist, Bartlett's-buildings, E.C.

**Oxygen Gas**, compressed into iron bottles, liquid nitrous oxide and carbonic acid.—Clarkson, Compressed Gas Chemist.

**Oxygen Gas**, compressed into iron bottles; prices on application.—Clarkson, 28, Bartlett's-buildings, Holborn, E.C.

Astronomical **Telescopes** of all kinds and Apparatus or Fittings made by A. Clarkson, 28, Bartlett's-buildings.

**Eyepieces.**—Huyghenian of any power to fit any telescope, 15s. each. Sun Diagonals, £1. Star Diagonals, 30s.

Astronomical **Telescopes**, second-hand, by best makers.—Clarkson, 28, Bartlett's-buildings, Holborn, E.C.

Model **Steam Engines** made or repaired. Separate parts fitted up, boilers made to order.—Lucas and Davies, 21, Charles-street, Hatton-garden, London.

**Tricycle House**, full size, portable, hold two bicycles, £5 10s., carriage paid.—X., 7, Clarence-street, Liverpool.

A few Gramme **Dynamos** for sale, cheap.—Walker and Olliver, 195, Severn-road, Cardiff.

**Electro-Motors** from 25s. No dead point. Battery equal Bunsen's. No fumes.—Walker and Olliver.

Leclanché **Cells**, Manganese, Sal-ammoniac, Bichromate Bells, Wire, Pushes. Wholesale and retail.—Walker and Olliver.

**Dynamos** repaired or rewound. Advice given. Competent men sent to all parts.—Walker and Olliver.

Send for **List** of Switches, Indicators, Telegraph Instruments, Parts, &c., for sale, cheap.—Walker and Olliver.

**Lamps**, 42 and 59 volt, Swan, £3 15s.—H. Hewitt, 21, Westbourne Park-crescent, Paddington, W.

**Leclanche Batteries.**—No. 1, 15s. 6d.; 2, 18s. 6d.; 3, 22s. Cash.—Address as above.

**Coca Leaves.**—The Bolivian Consul-General has sent a splendid testimonial this week in favour of their stimulating properties.

**Coca or Cuca Leaves.**—Many M.P.'s and Clergymen take them constantly. To Cyclists they are a positive necessity.

Persons afflicted with **Indigestion** should chew Coca instead of eating a hearty dinner, and they would soon be cured.

**Water Motors**, for sewing machines, organettes, window advertisements, 32s., 42s. List one stamp.—Wheeler.

**Fan Castings.**—Improved Registered Designs; sets 5in., 3s.; 6in., 4s.; 8in., 5s. Drawings, 4d.—Wheeler, Engineer.

**Water Motors.**—Complete one horse-power, £9. Half, £6. Quarter, £4. Eighth, £3.—Thomas Wheeler, Preston.

**Dynamo.**—S. Bottone has one second-hand, price £1. Lights a lamp, drives motor, works coil. Warranted.

**Standard Ohms.**—S. Bottone has a few of these on hand, price 2s. 6d.—Stanley-road, Carshalton.

**Wheatstone's Bridges.**—S. Bottone can also supply a few of these, price 5s., post free.

**Lathe**, 5½in. centre, self-acting, with change wheels, £9. Boiler, vertical, about 1½-horse, £6. Combined Engine and Boiler, 2-horse, £15. Slide-rest Lathe, 5in., £6.—79, Dudley-road, West Bromwich.

**Pianofortes** by all makers at 25 to 35 per cent. discount.—Dauncey, Stroud.

**Pianoforte.**—A good Pianette, walnut, warranted, 14 guineas.—Dauncey, Stroud.

"**See-Saw**" **Waltz**, post free, 1s. 4d. All music at one-third marked price, post free.—T. W. Dauncey and Son, Music Sellers, Stroud, Gloucestershire.

**Dynamos**, 5 and 10-light, warranted, to be sold at cost price.—Letters, Warne, 39, St. John's-street-road, E.C.

Halse's 12-guinea **Galvanic Battery**, complete, price 45s.—S., 20, Montpelier-road, N.W.

Dollond 4in. **Telescope**, finder, steadying rods, 4 powers, &c., cost £75, price £25.—S., 20, Montpelier-road, N.W.

Hardy **British Ferns**, including Polypodium, Semilacareum, Lastrea Æmula, Regida, Oreopteris, Thelyopteris, Colina, Athyrium, Lobatum. Aspleniums. Marinum, Viride, Ceterach Crenatum. Parsley. Beech, Oak, Calcareum. Veneris, &c. 15 Assorted Varieties. 1s. 6d.; 20 large Rockery Roots, 2s., 50, 4s 6d., 100, 8s.; botanically named, carriage paid.—John Burns, Fellside, Kendal.

2¼in. Astronomical **Achromatic Eyepieces**, garden stand, &c., perfect, 35s.; Bateman's 42s. microscope, 18s.—As below.

Half-plate bellows **Camera** (Ross), portable stand, double back. Stamp.—Fuller, 228, Grays Inn-road, London.

Genuine bargain.—Splendid **Beam Engine**, with large cylinders, governing balls, throttle valve, fly wheel, and hot air chamber, cost £9, will take 70s., or exchange for anything useful.—E. Wagstaff, 6 Hale-street, Islington, London.

**Dynamos**, Jones's Patent, 2,122, working at 12, Old London, in International Inventions Exhibition. Motor Castings, 3s. a set.—H. Jones.

**Formulas Worked Out** for winding Dynamos from 10 c.-p. to 500 c.-p., 6 stamps each.—H. Jones.

**Dynamo Castings**, Jones's patent H: 8 c.-p., 5s.; 16, 5s. 6d.; 20, 6s. 6d.; 30, 7s.; 70, 16s. a set.—H. Jones.

**Dynamos**, finished: 8 c.-p., 30s.; 16, 36s.; 20, 40s.; 30, 50s.; 70, 100s. each.—H. Jones.

**Dynamo Armatures** of above wired after fitted up 1s. each, own make, warranted.—H. Jones.

**Dynamos** for house lighting.—Jones's Patent Laminated Fields and Armatures, 5, 6, and 7 lights, £6, £7, and £8 each.—H. Jones.

**Dynamo Machines Repaired.** Motors, with wire, 5s. 6d.—H. Jones, 48, High-street, Lambeth, S.E.

**Euphonium**, 4 valves, by Antoin Courtois, C and B flat, in good order, in lockup case, complete, price 3 guineas.—S. Griffin, Lambourn, Berks.

**Instructions** in Tallow Melting, Refining, Lubricating Greases, Oils, Belting Grease. Hot Neck Grease, Heald Varnish.—G. D., Walter-street, Clayton, Manchester.

**Instructions** to make Gilders' Glue, Papermakers' New Glue Size, Glue Size Substitute.—G. D., Walter-street Clayton, Manchester.

**Instructions** in Refining Oleic Acid, Alizarine Oil. Turkey Red Oil for Dyeing, Soluble Oil.—G. D., Walter-street, Clayton, Manchester.

**Arc Lamp** for small dynamo, warranted to work with low power, free 6s.—Address below.

**Arc Lamp.**—Working Drawings for above, free, 8d.—Habgood, Hazelbrook, Buccleuch-road, West Dulwich, S.E.

Hand **Drilling Machines**, drill ¾in. holes 6in. from edge, from 25s.—S. Beeching, Mareham-le-Fen, Boston.

**Stylographic Pens!** Stylographic Pens!! Stylographic Pens!!! Only few left at 2s., postage, 1d. Each pen warranted. Post free, 2s. 1d.—H. Jones and Co., Viaduct-street, London, E.

**Dynamo**, new, laminated armature, lights 7 tens, 55s. Great bargain—J., South-cottage, Thurlow-park-road, Dulwich.

"**Electrician**," last four volumes, unbound, 14s. 6d.—Above.

**Microscopes** (Binocular and other). All kinds of Apparatus. Double, Triple, and Quadruple Nosepieces to the trade. Stamp for list.—R. G. Mason, from J. Swift, 24, Park-road, Clapham, London, S.W.

Model **Boilers** of copper. Low prices. All sorts. Send requirements for price.—Montgomery, Stanners-street, Greenock.

Howe treadle **Sewing Machine**, warranted in perfect working order. Price 30s.—E. Goodyear, New-road, Spalding.

**Batteries** (Leclanche).—No. 1, 12s.; No. 2, 15s.; No. 3, 18s. per dozen. Carbons, No. 1, 3s.; No. 2, 5s.

Single fluid **Bichromate Stone Jar**, 5 by 4, 2 carbons, 5 by 3, with screws, zinc amalg, with screw, 5 by 3 by ½, 1s. each.

**Bunsen's** from 1s. 3d. each; No. 2 Bichromate, 1s. 3d. stone cell, 6 by 4. Carbons, 6 by 3 by ½, 3s. dozen. List, 1d.

**Carbons Cut** any size or shape; zinc at 4d. per lb.: Pebble Carbon, 1d.—Geo. Reading and Co., Electricians, Lansdown-street, Birmingham.

**Thought-Reading**, Mesmerism, Ventriloquism, and Clairvoyance, complete instructions, 8d. each. All four, 14d. post free. Success certain. Never fails.—G. Marquis, Allhallowgate, Ripon.

**C. Pilkington**, 32, Sackville-street, Piccadilly, W., Magic Lantern Artist and Photographic Colourist.

Magic Lantern **Photograph Colouring**, finely and artistically done, 12s. per dozen. Special terms to the trade on application.—C. Pilkington, 32, Sackville-street, W.

**Chemical Apparatus**, wholesale and retail, for colleges, schools, and chemical works. New catalogue of 90 pages and 500 clear illustrations, post free, 2d.—William Hume, 1, Lothian-street, Edinburgh.

**Chemical Apparatus.** — Catalogue, 90pp., 500 illustrations, posted 2d.—W. Hume, Lothian-street, Edinburgh.

**Photographic Apparatus and Chemicals** for professionals and amateurs. See new illustrated catalogue, post free.—Hume, Lothian-street, Edinburgh.

Brazilian Pebble **Spectacle Glasses**, rough slabs or polished.—Richard Baker and Co., 9, Mincing-lane, London.

Brazilian **Pebbles and Crystals**.—RICHARD Baker and Co., 9, Mincing-lane, London.

**Mica**, otherwise Talc.—RICHARD BAKER & CO., 9, Mincing-lane, London.

Jocot **Pivoting Tool**, in case, for sale, nearly new; only 15s. 6d.—Hirst, 34, Union-street, Oldham.

The "**Spohr**" **Adjustable Chin-Holder for** the Violin. An important invention which is indespensable to every player.

The "**Spohr**" **Holder** can be fixed over the tail piece, as advocated in Spohr's School.

The "**Spohr**" **Holder** can be adjusted to any height or set to any angle to suit each individual performer; the head being always erect, and the instrument perfectly under control.

**Mons. P. Sainton**, the eminent violinist and professor at the Royal Academy of Music, writes:—

"I never used any **Chin-Holder** in playing, but after careful examination of the one you sent me, I am certain it must be a great help and comfort to violin players.

**Prices**:—Brass and mahogany, 6s. Nickel and ebony, 7s. 6d. Silver-plated, or gilt and ebony, 10s. 6d.

The "**Spohr**" **Violin Holder.**—JENOUR BROS., Sole Manufacturers, 213, Regent-street, London, W.

**Herr Polonaski** writes:—"I have applied it to the violin I usually play, and am very well pleased with the result. I consider it a most practical, ingenious invention, fully possessing all the advantages claimed for it in your circular, and I can therefore confidently recommend it to the attention of amateurs as well as professional players.

**Signor Erba**, Professor of the Violin at the London Academy of Music, writes:—"Signor Erba thinks it a great improvement on the others, and will recommend it."

**Price**:—Brass and mahogany, 6s.; nickel and ebony or velvet, 7s. 6d. Silver or gold plated, 10s. 6d.

The "**Spohr**" **Holder.** — JENOUR BROS., Sole Manufacturers, 213, Regent-street, London, W.

Revised and enlarged **Price List**, 1 stamp.—W. R. Smelt, Engineer and Tool Maker, 7, Goldsmith's-row, Gough-square, E.C.

Large Astronomical **Telescope**, 4¼ o.-g., 5 eyepieces' massive mahogany stand, £20.—3, Essex Villas, Fillebrooke, Leytonstone.

Also Ayrton and Perry's **Voltmeter**; Paterson and Cooper's Am-meter, and Elliott's Reflecting Galvanometer for £13.

Model Horizoztal **Engine**, 1½ stroke, on 10in. riveted boiler, 20s. Marine ditto, 37s. 6d.—99, City-road.

Dallmeyer's Stereo **Camera and Portrait Lenses**, £6 10s. Large Camera Portrait Lens and Tripod, 50s.—99, City-road.

**Violoncellos**, 2 fine old, 35s. and 65s. each; excellent condition.—37, Tyneham-road, Lavender Hill, Battersea.

**Incandescent Lamp**, 8d. post free. Send for one.—New and Co., 24, Dean-street, Soho.

**Incandescent Lamp** in Gilt Scarf Pin, 20 stamps.—New and Co., 24, Dean-street, Soho.

Pocket 2-volt **Batteries**, complete, 20 stamps.—NEW and Co., 24, Dean-street, Soho.

**Incandescent Lamp** set in spray of flowers, 20 stamps.—New and Co., 24, Dean-street, Soho.

**Incandescent Lamp**, Battery, Wire, Chemicals, Instructions, &c., in box, 2s. 6d.; free.—New and Co., 24, Dean-street, Soho.

**Electro Motors**, highly finished, work small models, 2s. 9d., free. Battery, 9d.—Cook, Little East-street, Brighton.

A model **Schooner Yacht**, 32 inches long, rigged complete, £1.—C. Weaver, Enniskillen.

**Recipes! Recipes!!** Stanley! Stanley!! Poplar!!! Poplar!!! (This column last week.) Add "Hop Bitters." More to follow.

**Lenses** to form negative astro eyepieces of high power, 4s. Ditto, for Pancratic Astro, 2s. 6d.—Wm. Nicholl, Roslea, Clones.

**Launch Engines** for sale, various sizes. Please state requirements.—John Middleton, 16, Hope-street, Glasgow.

**Lathes.**—Several Screw-cutting; also some back-geared Lathes for Sale.—John Middleton, 16, Hope-street, Glasgow.

Bisschop **Gas Engine**, 1½ man-power, also 3-man.—Smith, Higginshaw Post Office, Oldham.

4½in. back-geared **Lathe Heads**, Rests, &c., bargain, £35, and Copying Press. 15in. by 8½d., as new, 13s.—Williams, Willow House, Coval-road, Chelmsford.

Small **Dynamo** (Jones's), quite new, £2. Also Battery for running as motor, 7s.—H. E. Smallbone, 23, Clyde-street, Leicester.

**Steam Launches and Engines**, Boilers and Propellers for same, all sizes; state requirements.—Chennell, Eastville, Bristol.

**Tricycle Parts.**—Complete sets of Work for Front Steering, central geared, double driving, plain or ball bearings. Send for price list. Cabinet Photos of finished machines, 6d. each.—E. Edwards, 162, Kennington Park-road, London.

**Dynamo** (shunt), Siemens type, Jones's patent, laminated armature, will light brilliantly two 20 c.p. lamps from lathe wheel. Price £3.—A. H., 25, Orde Hall-street, Great Ormond-street, W.C.

**Inventors and Amateurs Assisted** in making Instruments, Models, and Patterns, &c., &c.—E. Chick.

**Scientific and Electrical Instruments** made for the trade.—E. Chick, 24, Woodbridge-street, E.C.

The Amateur's and Dentist's **Gas Engine.** Castings, 42s. Drawing, 5s. Litho, 3 stamps.—A. Dorrington, West Gorton, Manchester.

The Amateur's **Gas Engine**, fitted up in working order, £7 10s. Bargain. References.—A. Dorrington, West Gorton, Manchester.

Great Reduction.—50 Amateur **Drilling Machines**, Castings and Drawing only 3s. Drawing separate, 8 stamps.—Dorrington.

**List** of Castings and Working Drawings, 1 stamp.—A. Dorrington, West Gorton, Manchester.

**Lathe Heads**, Slide-rests, Beds, Standards, Chucks, Appliances, finished, machined only, or rough. See list.—W. R. Smelt.

**Models of Machinery** and Patentees' Models accurately made to scale or sketch. Moderate prices. Estimates free.—W. R. Smelt.

**Turning**, Boring, Planing, Screw-cutting, Patterns and Forgings. Moderate prices. Good workmanship. Estimates free.—W. R. Smelt.

**Incandescent Carbon Lamps**, low resistance, 3s. each. Fairy Lamps, 3s. 6d. Platinum Lamps, 1s. 3d., post free.—Todd, 14, Wentworth-road, Manor Park, Essex.

**Incandescent Lamp Holders**, new pattern, best in the Trade, 12s. dozen. Sample, post free, 1s. 3d.—Todd, as above.

**Patent.**—Five Shares of £50 each for sale.—Messrs. Snelgrove and Co., Wardrobe Chambers, Queen Victoria-street.

**Bichromate**, perfectly soluble in cold water, 10 per cent. higher electrical efficiency than potash. 7lb. sample, 7d. lb.

**Battery**, Bichromate, new, double salt. No crystallisation in cells. 56lb. lots, 5½d. per lb.—R. A. Lee.

Chaster's **Electro-Motor Castings**, 2s. 6d. set. As described in "E.M.," 1026, 1027, 1029, and 1041.—R. A. Lee.

Patent Primary **Battery** for above, or 5 incandescent lamps. £3 10s.—R. A. Lee, 76, High Holborn, London, W.C.

## Wanted.

Old **Microscopes**, by Adams, Amici, Baker, Dollond B. Martin, Pritchard (Goring's "Engiscope"), Varley, and other old makers.—J. Mayall, Junior, 224, Regent-street, London, W.

Agents Wanted on commission to sell a new Invention to users of steam power.—Apply Salford Injector and Ejector Co., Salford.

Agents Wanted.—Morgan's celebrated Improved Scale Preventing Compound. Nothing better or cheaper.—W. H. Morgan, Engineer, Gloucester.

Birmingham Goods, Jewellery, Watches, Furniture, &c. Agents wanted. Illustrated Book and Perambulator Price List, post free.—Henry May, Birmingham.

Wanted, the Index to 1st Vol. of "Knowledge." Good price given.—P. Watkins, Hoylake Cheshire.

Wanted, good Working Model Condensing Beam Engine with Boiler; also good sound Boiler, about 24 by 9in., with fittings complete; copper preferred.—Address, B. H. Blackwell, 50, Broad-street, Oxford.

Wanted, Constant Galvanic Battery, about twenty cells; must be in perfect order. Also Books on Medical Application of Galvanism.—Mail, Deacon's, Leadenhall-street, London.

Wanted, responsible District Agents (Commission) for new Cream Extractor.—Snelgrove and Co., Wardrobe Chambers, Doctors' Commons, London.

Wanted, a Half-horse Boiler; must be cheap and in good condition.—Apply, A. E. Sharp, Lockwood.

Wanted, good second-hand Machinery for Manufacturing Electric Apparatus. Also good second-hand Gas Engine, about 4 H. P.—Apply, Bruckelbers, Rue St. Michel, Antwerp.

Lathe wanted, about 4½in., screw-cutting, second-hand; must be cheap.—Thos. Ford, 66, Rosamond-street, E., Oxford-street, Manchester.

## Addresses.

Wanted, address of W. Wakefield, and name and publishers of a book of Recipes on "Glazes," advertised in E. M. some months since.—Please address, Thos. Plunkett, Portmarnock, Baldoyle, Ireland.

Wanted, addresses of Manufacturers of Tricycle Fittings and Parts.—Thos. J. Hopkins, Cradle Bridge Scouring and Dye Works, Trowbridge.

## Situations.

Wanted, intelligent Young Man with Mechanical ability to fit up Electrical instruments. State wages required.—Cornbrook Telegraph Works, Manchester.

Scientific Instrument Maker seeks Situation in Laboratory, or any place of trust; at present engaged at one of the first opticians in London.—Address, 99, Northcote-road, Wandsworth-common, S.W.

ESTABLISHED 1851

**BIRKBECK BANK.—**

Southampton-buildings, Chancery-lane.

THREE per CENT. INTEREST allowed on DEPOSITS, repayable on demand.

TWO per CENT. INTEREST on CURRENT ACCOUNTS calculated on the minimum monthly balances, when not drawn below £50.

The Bank undertakes for its Customers, free of charge, the custody of Deeds, Writings, and other Securities and Valuables, the collection of Bills of Exchange, Dividends, and Coupons; and the purchase and Sale of Stocks, Shares, and Annuities.

Letters of Credit and Circular Notes issued.

THE BIRKBECK ALMANACK, with full particulars, post free, on application.

FRANCIS RAVENSCROFT, Manager.

---

**The Birkbeck Building Society's Annual Receipts exceed Five Millions.**

HOW TO PURCHASE A HOUSE FOR TWO GUINEAS PER MONTH, with immediate Possession, and no Rent to pay. Apply at the Office of the BIRKBECK BUILDING SOCIETY, 29, Southampton Buildings, Chancery-lane.

HOW TO PURCHASE A PLOT OF LAND FOR FIVE SHILLINGS PER MONTH, with immediate possession, either for Building or Gardening purposes. Apply at the Office of the BIRKBECK FREEHOLD LAND SOCIETY, as above.

THE BIRKBECK ALMANACK, with full particulars, on application.

FRANCIS RAVENSCROFT, Manager.

OF THE

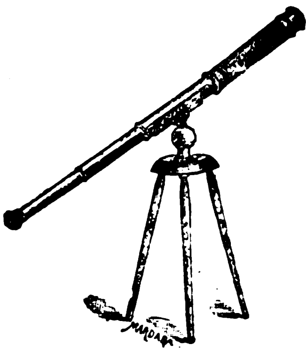
**BUILDING NEWS,**

PRICE TWELVE SHILLINGS.

Order at once of any bookseller, as only a limited number are bound up.

# J. THEOBALD & COMPANY'S

# SPECIALITIES.



THE COMBINATION consists in the instrument being a day telescope, night or astronomical telescope, and a sun telescope, all in one instrument. Over 25,000 are now in use all over the world. Very splendid astronomical observations can now be made.

The Combination Telescope has six very powerful lenses, of such remarkable strength that hills can be seen at twenty-five miles distant, flags at twenty, windows at ten, and time by church clocks at four to five miles off. In addition to this there is a powerful astronomical eyepiece, with two extra lenses, enabling the owner to examine the stars, Jupiter and his four moons, &c., &c. There is also a sun-glass, which will show distinctly the spots on the sun.

The following sizes can be had carriage free :—

No. 1, with three brass drawers and black morocco body, closing from 17 to 6 inches, packed in two neat cases, 12s. 6d. Magnifying power superficial, 784 times.

No. 2 ditto ditto, closing from 24 inches to 8½, with 16-line object-glasses, giving much more extended view, far clearer and longer definition, with also more powerful astro. eyepieces, 22s. 6d. Magnifies 1,521 times.

No. 3 ditto, ditto, 27 inches when opened, 10 inches when closed, far greater power and larger view, with nineteen-line object-glasses, 29s. Magnifies 2,500 times.

No. 4, with four drawers, twenty-two line object-glasses, a very popular size, and extremely powerful, 42s. Magnifies 4,225 times.

We have also made, in answer to many inquiries for such, a far more powerful class of instruments, called the Tourists' Combination Telescopes. These are made of the very best and clearest lenses that can be selected, and have a 30 to 35 mile range, and very superior astro-eyepieces. Each telescope has three or four brass drawers oxidised a dead black, with morocco-covered body, sling case and sunshade, complete, with nineteen-line object-glasses, £3 6s. ; or twenty-two line ditto, £3 18s.

The above telescopes are only made by us, and cannot be obtained elsewhere.

TELESCOPE STANDS.—We make a special gutter-shaped Telescope Stand (with movable legs) to take any size Telescope ; price, blacked wood, polished, 5s. ; or polished maple, 6s. 6d. Garden Stands, 5ft. high, 18s. and 35s.

Hundreds of testimonials, which it would cost too much to publish here ; but see our Illustrated Catalogue, post free, one stamp.

R. A. Proctor, Esq., the great astronomer, says of our Telescopes :—" Singularly cheap, excellent ; a perfect marvel for the price."

" Equal to any we have."—ENGLISH MECHANIC.

" An opportunity never before offered to the public." —*Christian Age.*

" A wonderful power of range."—*Pictorial World.*

Carriage to India, Ceylon, or the Continent 3s. extra ; to all foreign parts, 5s. ; to Canada or America, 8s.

## THE "ACME" FIELD GLASS NO. 1.

There are no glasses so highly recommended for power and cheapness as those sold by us. Why is this ? Simply because we lay ourselves out specially for this line of business ; we determine that we will get glasses of a quality so high, and a price so low, as to defy competition. The consequence is, we sell thousands where an ordinary optician would sell 10 or 20. Any person calling at our establishment can have over 3,000 glasses to select from, while to keep a stock like this would ruin half-a-dozen ordinary shopkeepers. Our glasses were used on board the ships bombarding Alexandria, and are used daily by large numbers of the officers in the Indian army. Travellers, tourists, and sailors alike speak loud in their praise. They are taken out by enterprising ship captains, and sold for double and treble our prices to passengers on board, and travellers across the water.

The Acme Field Glass will give a splendid view of 20 miles, will shew clearly the movements of birds that are but mere specks of dirt against the sky to the naked eye, the flags of a ship when only its topmasts can be seen on the horizon, a church clock three to four miles distant, and, in fact, for tourists, pleasure parties, sea voyagers, &c., it is an indispensable instrument—one which they cannot afford to be without. The object-glasses measure over one and a half inches across, and these, together with the other lenses, are of the clearest definition, and great power. To persons who cannot stand the fatigue of holding a telescope, we specially recommend it. In a neat black leather case, silk lined, spring snap, and strap, so that it can be slung across the shoulders. This wonderfully powerful instrument we offer for 15s. 6d., carriage free.

## THE "ACME" FIELD GLASS NO. 2.

Specially made in answer to many inquiries. The same size as the 15s. 6d. glass, but with 12 lenses. Gives a much larger view, and far greater magnifying power. An intensely powerful and clear glass. Price 37s. carriage free. Carriage to India on any of these glasses, 2s. extra ; all other Foreign places, 5s. Only an immense sale for these glasses will pay us at these prices.

"Exceedingly cheap."—*Christian World.*

" A thoroughly well made and powerful glass."—*The Baptist.*

"Gave us every satisfaction. Wonderfully cheap."—*Church Times.*

" Nothing better can be bought for the same money."—*Amateur Work.*

" I can thoroughly recommend them."—*Sylvia's Journal.*

Carlton Club, Pall Mall.

GENTLEMEN,—I am much pleased with your Acme Field Glass No. 2. It is marvellous to me how so perfect a glass can be made at such a small price as 37s., possessing such very high powers through its splendid lenses.

Yours obediently,

R. A. H. HIRST (Major).

As an inducement to persons to purchase at once, we have arranged a Grand Distribution of Prizes, which will be fairly distributed amongst those persons buying our Telescopes within the next few weeks. For these

## VALUABLE PRIZES

no charge whatever is made. Every person sending for an instrument before June 15 will receive a free ticket. The Prizes are nearly 300 in number, and are of the value of five guineas, three guineas, one guinea, &c., &c. For further particulars, see Catalogue. Tickets will be given as follows :— With every No. 1 Combination, one ticket ; No. 2, two tickets ; No. 3, three tickets ; No. 4 Tourist Combination, four tickets. No. 1 Acme Field Glass, one ticket ; No. 2, two tickets.

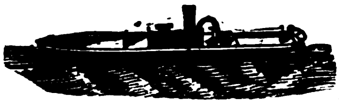
All persons must cut out the Coupon below, or mention the name of this paper, and send it with their order ; otherwise no ticket can be procured.

COUPON—ENGLISH MECHANIC.
This Coupon entitles holder to Glasses at above prices, and to Prize Ticket free.
(Signed) J. THEOBALD & CO.

**THE KENSINGTON AMATEUR PRINTING APPARATUS.** — For cards, note-paper, bill-heads, &c. Strong wooden press, assortment of ink, type, dabber, and instructions complete. Carriage free, 2s. 9d. Much larger sizes, 3s. 9d., 5s., 6s. 6d., 8s. 6d., 10s. 6d., 15s., 17s. 6d., 21s., and 25s.

**THE KENSINGTON SECRET SWORD CANES.**—Invaluable for self-defence. Have the appearance of an ordinary walking stick, but each contains secret steel sword. Carriage free, 1s. 9d., 2s. 3d., 2s. 9d., 3s. 6d. Better quality, 4s. 6d. Very superior, with secret spring, 5s. 6d., 7s. 9d., 9s. 9d., 12s. 6d., 15s.

**THE KENSINGTON SCREW STEAMER.**—Entirely of metal. Propelled through the water by steam for half-an-hour at each operation.

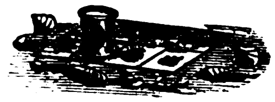


9½ inches long. Painted in two colours, and with boiler, lamp, steam-pipe, fan-wheel, screw, and rudder complete. Post free 1s. 9d. Larger sizes, 5s. 6d., 6s. 6d., 11s., and 13s.

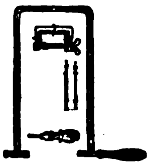
**THE KENSINGTON MUSICAL TOP.**—A most wonderful novelty. Directly this top is spun it commences playing music, owing to musical notes inside. Post free, 15 stamps. Larger size, 20 stamps.

**THE KENSINGTON MODEL STEAM ENGINE.**—Works by steam for one hour at each operation. Strong metal boiler, brass flywheel, lubricator, brass supports, tripod stand, and furnace, complete. Post free, 15d. Larger and better models, 3s. 3d., 4s., 7s. 6d., and 10s. 6d.

**THE STUDENT'S MICROSCOPE and 200 Objects.** Has obtained high-class awards at various Exhibitions. A strong, powerful microscope, magnifying many thousands of times, with 200 beautiful objects, shells, stones, insects, &c. Carriage free 20d.



**THE PARISIAN RAT TOBACCO POUCH.**—Ladies scream on seeing it. Life-size and life-like Rat, of best flexible indiarubber, coloured exact, forms tobacco pouch. Post free 18 stamps. Will fold up into any compass. Oyster Shell ditto, 1s. 6d. Bloater ditto, 1s. 6d. Revolver ditto, 2s. 2d.



**THE AMATEUR'S FRET-SAW OUTFIT,** comprising good steel fret-saw, frame, assortment of saws, iron cramp, files, bradawl, and patterns, complete. Carriage free, 3s. Nickel-plated, 4s. Better quality, with drill and bits, 4s. 6d.

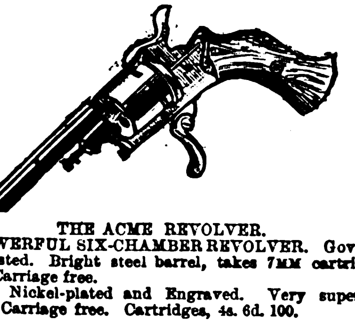
**THE ARTIST'S COPYING APPARATUS,** for enlarging drawings, photographs, &c., to life size, or any size required, by a very simple process, which can be managed by any child. Post free 14 stamps.

**THE PHOTOGRAPHIC CABINET.**—With this apparatus any person can take Photographs of their friends equal to a professional photographer. The apparatus consists of drying frame, sensitised paper, chemicals, bottle of gold solution, glass rod, elastic bands, cards for mounting, and full instructions. Carriage free, 2s. 3d.

**THE CHAMPION AMERICAN WRESTLERS.**—Selling by thousands. These amusing figures jump about and start up and down with life-like reality, first one gaining the ascendency and then the other. Endless fun. Post free, 10 stamps. Best quality, 20 stamps.

A VERY SPECIAL OFFER.

**THE ACME REVOLVER.**—We offer the following powerful Revolver for 14 days only at a clearance price. Each Revolver guaranteed.



THE ACME REVOLVER.

A POWERFUL SIX-CHAMBER REVOLVER. Government tested. Bright steel barrel, takes 7MM cartridge. 8s. 6d., Carriage free.

Ditto, Nickel-plated and Engraved. Very superior, 10s. 6d., Carriage free. Cartridges, 4s. 6d. 100.

**GRAND ILLUSTRATED CATALOGUE, 400 ENGRAVINGS, AND SPECIALITIES OF EVERY DESCRIPTION, POST FREE, ONE STAMP.**

**Established in Kensington over 50 years. Telephone 3218.**

# THE TERRESTRIAL TELESCOPE.

By Edward M. Nelson.

HARDLY a week passes without a reference in these columns to celestial telescopes; but somehow or other the terrestrial telescope has been left out in the cold. Perhaps it will be urged that they are identical, excepting only the inversion of the image, and that if they will stand the tests for the higher work it will be unnecessary to test them for terrestrial purposes. Another reason for the want of attention given to this subject may arise from the greater popularity of binocular Galilean field glasses.

It is true that in the navy one still sees a 2ft. telescope of 1¼ aperture freely used; but from the merchant service the telescope has quite disappeared. It is not easy to account for the decided partiality the public have for the binocular Galilean glass to the monocular four-lens eyepiece telescope. The cost can have nothing to do with it, for in this respect they are on a par. As far as weight and bulk go, the telescope has the advantage. Can it be that the binocular glass is more useful than the telescope? It is true that a telescope would be out of place in a theatre, neither is it of much use on a racecourse. On a steamer the vibration from the engine renders the use of a telescope impracticable; and for making land on a dark night the telescope must give way to its double rival; but for every other purpose the monocular telescope, with the four-lens eyepiece, is undoubtedly the better instrument of the two. One very often hears of a pair of binoculars being given as a present, or a prize, quite regardless of the fact that a pair of binoculars is like a pair of boots—to be of use they must fit. So important is it that the centres of binoculars should exactly correspond with the centres of the eyes of the person using them, that a slight divergence of even $\frac{1}{16}$in. is, in my own experience, quite sufficient to detract from the pleasure of using them. The field of binoculars is unsatisfactory. There is a central disc, scarcely as bright as the rest of the field, where the image is at its best (such as that is), the picture in the remaining annulus being chromatic and woolly. If my memory is correct, "A Fellow of the Royal Astronomical Society" has stated that the nearest approach to optical perfection must be sought for in a lens whose focus = 15 times its aperture. What shall we say, then, of the binocular field glass, the focus of whose objectives does not exceed 3 times their apertures.

The popularity of field glasses may be accounted for, I think, by the ease with which they are held and adjusted, the general public being better pleased with powers of 4 to 8 without trouble, than with higher powers and more critical pictures with trouble. It is a sad fact that at the present day the terrestrial telescope is only to be found in the hands of scorers for rifle shooting, and of a few infatuated individuals who still persist in carrying about these antiquated instruments. To pass on to the legitimate part of our subject, we shall have to consider what are the different classes of terrestrial telescopes, and what the most useful apertures and powers, and then how to test them.

1st. The different classes of terrestrial telescopes. It will be said that if we want to find out what are the different classes of terrestrial telescopes, we ought to consult the makers' catalogues. If we did that we should find every kind of monstrosity, from a 1in. equatorially mounted to a 3in. with ten draws, shutting up to 6in. for the pocket!

There are in reality four classes of terrestrial telescopes, viz.—1, Pocket hand-glasses; 2, Look-out hand-glasses; 3, Portable telescopes on a stand; 4, Non-portable telescopes on a stand.

1. Pocket hand-glasses should have an aperture of 1in. to 1¼in., and four to six draws, so that they may be shut up into a small compass. For my own part, I dispense with the slings and straps, preferring to carry it in my pocket. I have carried one of these telescopes for some years, and should now, if I went without it, miss it as much as my watch.

2. Look-out hand glasses are those such as are used by coastguards, or what you would keep on a rack in the house ready for any emergency. Aperture from 1½in. to 2in.; they should only have one draw. They should be fitted with a long sunshade, at least 1½ times the aperture, as it is an excellent protection from rain and dust. A look-out glass, for use in all weathers, and in every direction with regard to the sun's rays, should have a brilliant image, and be consequently of low power.

3. Portable telescopes on a stand. The aperture for these should be 2in., and this is, I think, the largest aperture that ought to be made portable, and the smallest that is worth putting on a stand. A telescope of this calibre should not have more than three draws, for fear that the optic axis of the eyepiece may not coincide with the centre of the object-glass. The stand should be a small tripod pillar and claw, with a compass joint movement in altitude, and with a movement in azimuth as well. The compass joint should have a clamping screw.

4. Non-portable telescopes on a stand.—The apertures for these may range from 2in. to? We will leave the consideration of the limiting aperture of these instruments until we have discussed the size of emergent pencils. The object-glass should be mounted like a celestial telescope in a single tube, with a rack and pinion tail-piece. The stand may be either a pillar and claw or tall wooden tripod. If the former is used the telescope should be fixed to one side of the pillar by a cone bearing, and not by a compass joint to the top of the pillar. There ought to be a screw and washer for tightening up the cone bearing. The telescope should be fixed at its centre of gravity (the cap being taken off); steadying rods may be dispensed with.

If the tall wooden tripod is chosen, it may have a metal top similar to the pillar-and-claw stand; or if with the common top, the telescope should be mounted on trunnions, at its centre of gravity, and have draw-tube steadying rods. A very good telescope stand (non-portable) may be made as follows: A stout board, about as long as the telescope, forms a kind of table; the board should be 6in. wide at the object-glass end, and 2ft. wide at the eyepiece end. The board should slope down from the object-glass end to the eyepiece end about 1 in 4. At the object-glass end there is a leg, with no caster on it, and on the board a boat's row-lock to take the telescope; at the other end there should be two legs, both with casters, and on the board a movable block of wood, with a V cut in it, to put under the telescope, on the object-glass side of the rack-and-pinion tailpiece.

## The Power of Terrestrial Telescopes.

It must be remembered that in observing terrestrial objects one is looking along the densest part of the atmosphere, which is usually very unsteady in the heat of the day. With celestial objects the case is different, because in looking upwards the atmosphere is always getting clearer and less dense. If one considers how clear the air is, even at the top of a mountain only 5,000ft. above sea-level, the enormous difference between looking in a horizontal direction through five miles of dense atmosphere, and looking vertically up through it, will be easily understood.

Another point is this: that the scientific method of arranging powers, both for celestial and terrestrial telescopes, is, and has been, according to their emergent pencils; in other words, so much per inch of aperture. Example: An emergent pencil of ·033 means a power of 30 per inch of aperture. This, I think, as far as terrestrial telescopes are concerned, is an erroneous method altogether. About terrestrial telescopes I can speak definitely, as I have made the necessary experiments; but not so with celestial telescopes. The conclusion I have come to is, that there is imposed by our atmosphere a limit to power, no matter how large the aperture of the telescope may be.

In determining what this power was, I had recourse to actual experiment on objects distant from 3 to 5 miles, and in these experiments I disallowed all pictures that resembled the appearance of a white stone when seen beneath a clear rippling stream. In former days the method employed was to put up a logarithm table about 60 yards off, and then increase the power until it could be read. By this it was found that an emergent pencil of ·025, on a power of 40 per inch, could be used with advantage on a bright day. This may be very true; but it eliminates the interference of the atmosphere altogether.

The conclusion I came to was that on average fine days a power of 30 was as bright as you could go to with advantage. On extraordinarily fine days this might be increased to 40. I have never used a power of 50 on any aperture which does not make the presence of the atmosphere unpleasantly conspicuous. It must be remembered that it is not the telescope we are testing, but the atmosphere. A few hints may be useful as to the object which should be chosen for these experiments. Do not choose an object such as the vane on a church steeple, standing out black against a bright sky. Neither a bright white house, which, as you stand with your back to the sun, you see in front of you lighted up as a conspicuous object. Choose rather a railway semaphore under the shade of a hill as you look in the teeth of the sun's rays. The power that will best show you the colour of the arm is the most suitable for the telescope. My remarks are, of course, not addressed to those who have an eyepiece for every emergency; such as one power for looking into the sun's rays, another for looking away from the sun's rays, &c., but to those whose telescope has only one eyepiece—my aim being to give them a few hints as to the power that eyepiece should have.

## Emergent Pencils.

In a properly constructed telescope the diameter of the emergent pencil is equal to $\frac{a}{p}$, aperture divided by power. Now it will be easily understood that if you have a very small emergent pencil, say ·02, the pupil of the eye will not be filled with light, and in consequence the image will be darkened. Again, if you have a very large emergent pencil, say ·4, it will be larger than the pupil, and therefore the eye will not be able to take it all in. Hence, it appears that light is increased with the increasing size of the emergent pencil, but only up to a certain point, when any further increase is useless. The question now to be decided is, what is that point. By experiment I have found on an ordinary bright sunny day, when not looking into the sun's rays, that if an emergent pencil of ·1 be increased to ·11 the increase of light will be perceptible, but if it be further increased to ·12 there will be no increase in the amount of light—*e.g.*, while, with a power of 25, there will be a perceptible increase of light in a 2¾in. over a 2½in., the difference between a 2¾in. and 3in. will be imperceptible.

We are now in a position to answer the question about the limit of aperture for terrestrial telescopes. We have found the maximum power to be 40, and if with that power the emergent pencil is to equal ·11, it follows that the limit of aperture will be 4·4in.

### Tests for Telescopes.

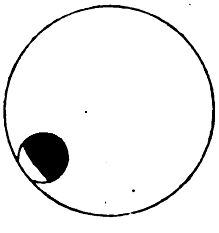
This subject is a difficult one, as it is not possible to state definitely what object ought to be seen by a certain telescope. It is not difficult to find which is the better of two telescopes of the same aperture and power, by trying them on the same object at the same time. But it is difficult to say if a certain telescope is a good one, as it necessitates the knowledge of the picture a similar telescope of known excellence would give under similar circumstances. Some will say: Why not treat them like celestial telescopes, and test them on celestial objects? To which I reply, that the method is a very good one, especially for the larger instruments, but it requires a whole battery of eyepieces. Tests for telescopes, as well as microscopes, are comparative, and require, therefore, much knowledge and experience.

A very good test for the uninitiated is to ascertain how far a logarithm table can be read by the naked eye; then measure the power of the telescope; then see if you can read the figures at a distance equal to the product of the distance they were read by the naked eye and the magnifying power. By carefully attending to the following directions a few unsuspected and important defects may be detected and rectified. Unscrew the cap from the eyepiece of the telescope and focus at some distant object; turn the telescope round, and look through the object-glass end at the disc of light seen at the eyepiece, keeping the eye some distance from the object-glass. Move the telescope so that this disc of light comes to the margin of the object-glass. If the margin of the object glass (*i.e.*, the edge of the cell) eclipses this disc of light, all is well; but if this disc of light goes out before it gets to the edge of the cell, or a blue-black, dark patch comes on it before it is eclipsed, then it shows that either the hole in the diaphragm of the erector of the eypiece is too small, or that the diaphragm is not in its right place (Fig. 1). The first thing to be done is to put the diaphragm in its right place, and that is in focus of the lens which is nearest to the object-glass of the telescope. Having done that, place the eyepiece back in the telescope, and go through the test again. If that blue-black patch still comes on before the disc is eclipsed by the cell of the object-glass, it shows that the hole in the diaphragm is too small. The remedy is to broach the hole out little by little until you get it right. The test should be constantly resorted to during the operation, so that the hole may not be made larger than necessary. This fault is one which can only be met with in terrestrial telescopes, as celestial telescopes have no erector in the eyepiece. The action of the too-small hole in the diaphragm of the erector is curious. It merely darkens the picture. It does not act in the same way as a diaphragm between the object-glass and eyepiece which cut off aperture would. That diaphragm is put into a telescope to sharpen up the image from an object-glass, which is defective from spherical aberration, and it also darkens the image by the contraction of the aperture. Not so, however, the diaphragm in the erector, that merely darkens the image without sharpening it at all. The rays from the object-glass have come to a focus, and the image, good, bad, or indifferent, has been formed. Any diaphragm in the microscope, which magnifies and inverts that image, can have no effect in improving its quality.

Reverting to our test, if the disc of light is eclipsed by a diaphragm concentric to the cell of the object-glass, before it comes to the margin of object-glass it shows that there is a diaphragm, cutting off aperture, between the object-glass and the eyepiece (Fig. 2).

Another test to discover if any aperture is cut off is to focus the telescope on a distant object, then point it to the clear sky. Put a small piece of paper over the top of the cell of the object-glass, in such a way that a small piece of it projects 1-16in. on to the object-glass over the margin of the cell. Now examine the spot of light at the eyepiece end (the emergent pencil) with a lens, and see if you can perceive the piece of paper projecting on the disc. If you cannot see the paper, it shows that the aperture is cut down by a stop. Having put the telescope through these tests, the magnifying power may be measured in the usual way, by dividing the diameter of the object-glass by the diameter of the emergent pencil. Great accuracy is required in the measurement of the emergent pencil; an error of ·004 would make a difference of one diameter in a power of 27 on a 3in. object-glass—e.g., a power of 27 would have an emergent pencil on a 3in. of ·111, and a power of 28 one of ·107.

F I G. 1.



F I G 2

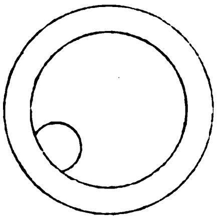


Fig. 1 shows the blue-black patch coming over the disc of light before it is eclipsed by the margin of the object-glass.

Fig. 2 illustrates how the disc of light is eclipsed by a diaphragm between the object-glass and the eyepiece.

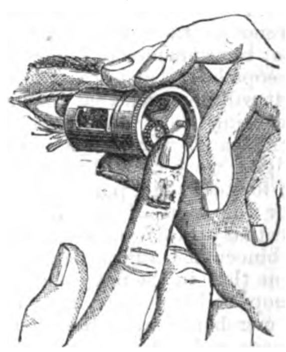
It is of no use attempting to measure the magnifying power of a telescope until you have applied the tests mentioned above to it, for this very good reason: that the disc of light at the eyepiece end may not be the image of the whole of the object-glass; but it may be either the image of a stop between the object-glass and eyepiece, or the stop in the erector of the eyepiece. In either case it would make the diameter of the emergent pencil less than it really was, and so falsify the magnifying power by making it too high.

I broached out the hole in diaphragm in the erector of a telescope by a very eminent maker, who had engraved the power of 50 in the eyepiece; I measured the power after the operation, and found it to be 40. This is only one instance among many.

I was surprised to find, on trial the other day, that my binocular glasses, aperture 2¼, power 8, and my 1½ telescope, power 15, had the same extent of field. In conclusion, a small piece of advice: Prefer a small, bright image, to a large and darker one. Practise yourself in the interpretation of small images. It will soon become a habit, and then you will easily walk to windward of your high-power critics.

## THE LABBEZ TELEMETER.

THE Labbez telemeter is a portable range-finder and surveying instrument, by means of which distances can be found with great rapidity and approximate accuracy, as a single observer can make an estimate in about 30 seconds, or, with the assistance of some one to "dress" the observer with the object, in from 15 to 20 seconds. The instrument consists of a cylinder 1¾in. long by 1in. in diameter, containing two reflecting planes set at an angle of 45° and giving by reflection 90°. These planes can be moved through a certain arc by revolving the cam-piece at the end, which acts upon a pin fixed to one of the mirrors. An adjustment for the other mirror is provided in a cogged-head screw. This cogged wheel and the scale being set at zero, the observer who wishes to find the distance of an object looks about for something which will serve as a "mark," and be as nearly as possible at right angles to the object. Holding the instrument as shown in the figure the observer looks through the small hole and turns the cogged wheel until the image of the object is superimposed on that of the mark. The observer now walks in a straight line 30 yards towards the mark, and having been "dressed" into line with that, again looks through the instrument and rotates the end of the cylinder until the object is reflected over the mark. The line opposite the fixed zero on the scale will then indicate the reading of the distance of the object in yards without any calculation. The advantages claimed for this instrument are no necessity for pickets; an exact right angle triangle need not be plotted; and any base can be used proportionate to 30, providing the result, as shown by the scale, is corrected in same ratio. When employed for small objects or long distances an opera-glass or telescope attachment is fitted. Specimens of this telemeter are shown by the sole agent for this country, Mr. J. H. Steward, 406, Strand, in Group 25 at the International Inventions Exhibition. The instrument can be used for finding the breadths of rivers, lakes, channels, &c., and, as instances of the approximate accuracy with which it works, it may be mentioned that at the School of Musketry, Hythe, estimated distances of 1,890, 790, and 300 yards were found on measurement to be 1,900, 800, and 300 yards respectively; while in some experiments made by Col. Edgcombe, R.E., on Runnymead, estimated distances of 1,950, 1,200, and 500 yards were found by actual measurements to be 1,930, 1,200, and 500 respectively. Obviously, much depends on the observer; but a little practice will enable any one to estimate distances with all the accuracy needed in practical work.

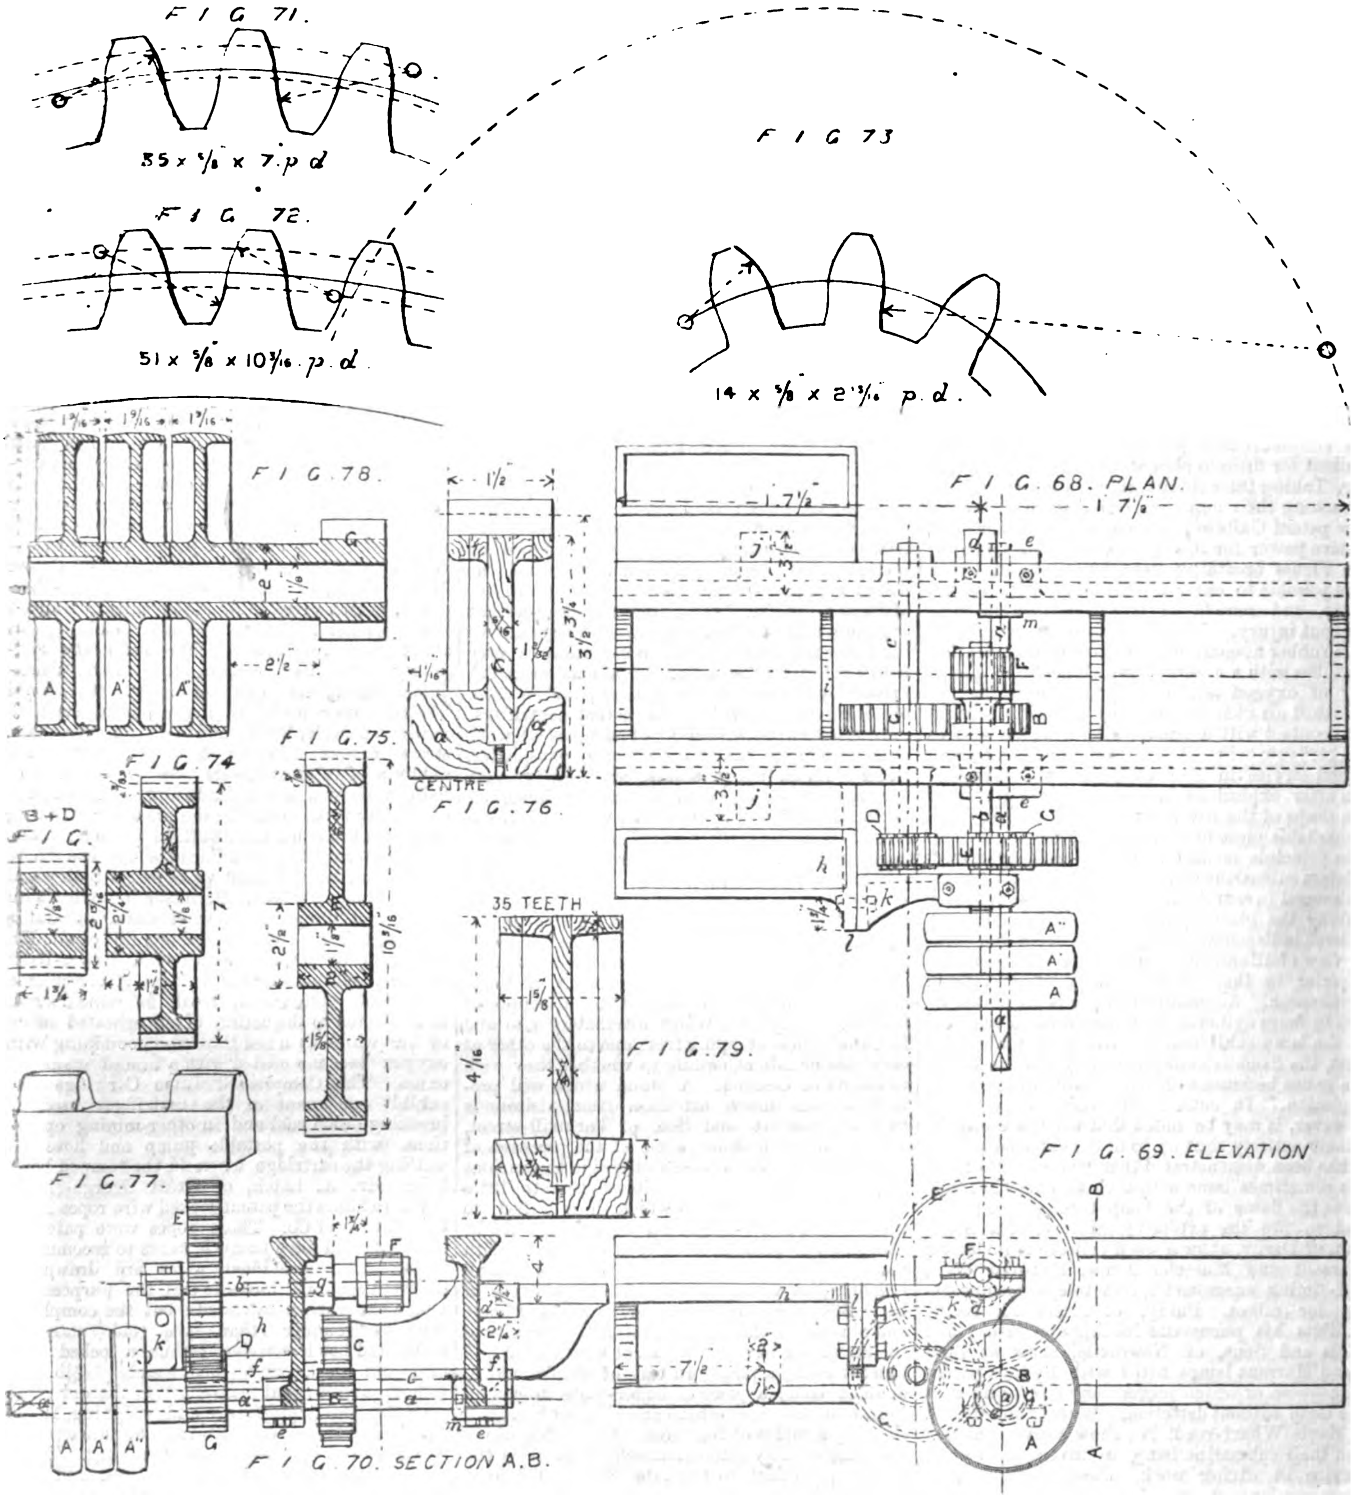


## THE INTERNATIONAL INVENTIONS EXHIBITION.—III.

### Mining and Metallurgy.

THE division of the exhibits into groups is not quite so satisfactory as it might have been, for some of the groups contain objects which do not properly belong to the class, while exhibits which do have been relegated in some cases to other groups. For instance, one of the most attractive exhibits in Group II., Mining and Metallurgy, North Court, South Gallery, is found at Stand 150, where Messrs. J. Rhodes and Sons, of Wakefield, show several of their ingenious machines for working sheet metals. So far as the general body of visitors are concerned this is probably the most interesting exhibit in the group, but it has very little connection with mining and metallurgy. Here the visitor can see with what ease and simplicity tin-plate boxes and pans are stamped out of the sheet metal and embossed with inscriptions; for at one machine the body of the box is stamped out perfect at a blow, and at another the lid, ornamented with a device and lettered, is also produced with a single stroke. Pans, pie-dishes, &c., require a little more work; but in this case one machine is employed to cut the metal from the sheet and shape it roughly into form, and another of rather more complicated design is used to finish the article. A small pan or pie-dish, for instance, stamped into shape is put upon a form in a machine which has some resemblance to a lathe; the back support is run up to hold it in position, and a tool then trims the edge, doubles it, and rubs or burnishes the article into a finished condition. It is fitting that an exhibit of this kind should be placed where the greatest number can witness the operations performed, and we presume that accounts for its position; but it should properly have been in the group devoted to metal-working machinery. On the other hand, mine surveying apparatus has been placed in the group devoted to philosophical instruments, especially when exhibited in company with other apparatus, for the simple reason probably that it is not convenient for firms to have stands all over the building. Taking the exhibits, then, in something approaching their numerical order, we find near the new patent Galloway engine, which provides the motive power for this group, some specimens of the Fleuss breathing dress, by means of which it is possible to enter a mine filled with choke-damp, and remain in it a considerable time without injury. The dress consists principally of a rubber nose-and-mouth piece communicating by tubes with a reservoir which contains a supply of oxygen and a receptacle in which the breathed air can be revivified by being brought into contact with a caustic alkali, which absorbs the carbonic acid. The Fleuss dress has been of signal service in connection with the saving of life after explosions in coal-mines, and also, in the shape of the diver's helmet, in performing a remarkable piece of work at the Severn tunnel. The principle is also utilised in making an oxy-calcium submarine lamp. Safety-lamps are shown by several inventors and exhibitors, the majority having the glass cylinder which is now considered indispensable, and which, from the point of view of illuminating power, is immeasurably superior to the old gauze type of Davy and Stephenson. Access to the flame is prevented by two or more cylinders of gauze, and in the case of the lamp exhibited by Evan Evans, of Llanrwst, the flame is extinguished by the gas before the gauze becomes sufficiently heated to cause an explosion. In connection with safety-lamps, however, it may be noted that what is wanted is a lamp entirely shut up from the external air, for it has been demonstrated that "blowers" of foul gas sometimes issue with such velocity that they force the flame of the lamp through the gauze, and so fire the explosive mixture. Davis and Son, of Derby, show a good collection, including Marsaut and Mueseler lamps, improved dials, self-timing anemometer, and telephonic apparatus for mines. Purdy, of Eastwood, Notts, exhibits his pneumatic locking apparatus; and Mills and Sons, of Newcastle, show at their stand Marsaut lamps fitted with Ryder's patent lock—both of which prevent any tampering with the lamp without detection. Barnett and Foster, of Eagle Wharf-road, N., show a diver's helmet and their submarine lamp, an invention of great service in diving work. Justice and Co., of Chancery-lane, show a large-size model, partly in section, of the Casson-Bicheroux direct-acting gas furnace and producers for heating and smelting metals; and Henry Simon, of Manchester, exhibits in diagrams and model the Simon-Corvés coke ovens, which formed the subject of an interesting discussion at the recent meeting of the Iron and Steel Institute. The object of these ovens is, while producing coke suitable for all the purposes of the metallurgist, to secure the products of distillation. From the experiments of Mr. I. Lowthian Bell, as detailed in his paper, it would appear that coke so made is inferior to that produced in the ordinary ovens; but on this point there is much diversity of opinion, Prof. Armstrong, for instance, holding that, from a chemist's point of view, the method of coking at a high temperature is irrational. It is certain, however, that coke produced in the Simon-Carvés ovens is in demand for many purposes.

Head, Wrightson, and Co., of Stockton-on-Tees, exhibit a large-size model of a centre crane for Bessemer plant, as used at the works of the North-Eastern Steel Company, Middlesbrough. The object of this crane is to obtain automatic balancing with a variable weight in the ladle. It is of the hydraulic type and carries 15 tons at a rake of 25ft., and the maximum horizontal strain at top of post does not exceed 4½ tons. Rock drills of all patterns, worked by steam, air, water, or hand power, are shown in great variety, many of them at work; and in Group III., Engineering Construction, the Beaumont boring-machine is shown by the South-Eastern Railway Company, with large models of the Channel in the course of the proposed tunnel. The Aqueous Works and Diamond Rock-boring Company exhibit their improvements in rock-boring apparatus in the shape of a portable prospecting diamond boring tool, with a number of cores extracted from different bore-holes. This arrangement differs from rock drills, which merely make holes for blasting purposes, as the cores are extracted in the solid, being cut out by an annular bit set with diamond tools. Hayward, Tyler, and Co., of Whitecross-street, have a good exhibit of their steam pumps specially adapted for mining purposes; and Rebey and Co., of Lincoln, have in this group a 12 h.p. winding engine with locomotive boiler mounted on patent wrought-iron tank foundations, into which the parts can be packed for transport. Crushing machines are shown by several firms, among which may be noted the patent knapping-motion ore and stone crusher of Baxter and Co., Leeds, and the dead-weight crushing mill of Chas. Sheppard, Bridgend. In the latter the material is carried under a very heavy roller by the action of a smaller roller driven by power. Askham, Bros., and Wilson, of Sheffield, show Lucop's patent centrifugal pulverisers, with a number of samples of work done by them in the shape of ores, phosphates, fuller's earth, sugar, spices, &c. Safety gear for mining cages, with automatic detaching hooks, is exhibited by several firms, and Lewis and Massey, of Aberdare and Twyford, show the application of their apparatus for preventing over-winding to the steam valve and reversing lever of an ordinary winding engine. Mr. Pichler, of Great Portland-street, exhibits a working model of a balance double-acting man-engine, for use in mines instead of cages or ladders. For the benefit of those who do not know what a man-engine is, it may be likened to a couple of ladders, side by side, which alternately rise and fall, the miners stepping from one to the other at each rise or fall, according to whether they wish to ascend or descend. A stand which will probably attract much attention from visitors is that of Bennett and Son, of Turnmill-street, E.C., at which is shown some of the processes of gold-beating. In a case at the side the various stages of the process are exhibited, from the little ingot and the ribbon into which it is rolled, to the finished leaf 1-300,000th of an inch thick. The stand of greatest interest in connection with metallurgy is, however, that of Thomas and Gilchrist, at which a number of specimens of basic Bessemer iron from different works at home and abroad are shown. To exhibit the ductility of the metal, we have specimens of wire beaten and twisted cold; a ramshorn test of ship's angles, doubled cold; a piece of boiler-plate folded in four, and numerous other examples, with a case showing samples of fractures. An exhibit which has a melancholy interest attaching to it is the casket presented to the late Sidney Gilchrist Thomas by the ironmasters of the Prague Society. The repoussé work is of basic ingot iron, while the figures are cast from pig iron as used in the Bessemer converter. Sir H. Bessemer exhibits in an unnumbered case an historical collection of original test pieces of Bessemer iron and steel, some of which date as far back as 1856. Mr. Snelus, of Workington, exhibits in model form illustrations of improvements in the processes of manufacture of steel, including apparatus for carrying hot steel ingots, and improved steel linings for Giers's soaking pits—a model of a pit being shown, with the appliances for handling the ingots. The deputy-master of the Mint exhibits the method of refining gold by the chlorine process devised by F. B. Miller, of the Melbourne Mint, and Prof. Chandler Roberts also shows a full-sized model of the battery for reducing chloride of silver, in which plates of zinc and cast slabs of the chloride of silver are placed in a weak solution of chloride of zinc, the silver being reduced in about 24 hours. He also shows a Stas pipette, modified by Mr. P. du Bois, of the U.S. Mint, Philadelphia. The continuous mercurial rain amalgamator of Dr. Atcherley is exhibited in working order. In this apparatus troughs are supported above the washing water and drop a continuous rain of mercury in order to seize upon the float and flour gold—light particles which would otherwise escape with the water. Cassel's process of extracting gold from refractory ores by chlorination is shown at the adjoining stand. Instead of using the gas in the free state it is evolved in the apparatus itself in the nascent state in contact with the ores, and oxygen being also generated at the same time, which oxidises the sulphides, arsenides, &c., the gold is seized upon by the nascent chlorine and converted into terchloride. The addition of lime prevents the iron in the pyrites from passing into solution. The Electro-Amalgamator Co. exhibit in working order their apparatus for extracting gold and silver from ores by the combined action of electricity and mercury, the current being employed to keep the mercury bright and lively. The Phosphor Bronze Co. show a variety of castings, &c., and their special silicium bronze wire, which has been found so useful for telephone and telegraph over-head-lines; and at the adjoining stand the Manganese Bronze Co. exhibit articles in their special metals, with a bent propeller-blade from the *Mosel*. The use of a peculiar-shaped two-bladed propeller for ventilating purposes is shown in the shape of the patent Crossley Air-Propeller, which gives a rapid movement of air at low pressure. It is shown running at about 800 revolutions, and from the simplicity of its construction, and consequent cheapness and economy, it should be found very useful in many places, such as mines and mills, hotels and theatres, hospitals, steam vessels, tunnels, &c. Amongst other exhibits of interest Messrs. Bailey and Co., of Salford, show a hydraulic hauling engine of the oscillating type, specially designed for working at a pressure equal to 1,200ft. in column; a one horse water motor of similar type for use where town water has sufficient pressure; a Bailey and Reid's cement tester; Professor Thurston's oil tester, and Stapfer's somewhat similar apparatus for ascertaining the lubricating value of oil. Mr. G. Bower exhibits drawings of a Bower-Barff furnace, and specimens of iron and steel rendered rust proof. The metal, it will be remembered, is subjected to the action of superheated steam or air while at a red heat, and combining with oxygen becomes coated with a film of magnetic oxide. The Compressed Lime Cartridge Co. exhibit specimens of the cartridges used in breaking down coal and in other mining operations, with the portable pump and hose for wetting the cartridge when in the tamped bore-hole. Mr. A. Latch, of Great George-street, S.W., exhibits the patent locked wire ropes made by Elliot and Co. These ropes were patented last year, and have many features to recommend them. The individual wires are drawn to different sectional forms to suit the purpose for which the rope is intended; but the completed rope is rounder than the old standard make, and has less weight; thus, a locked coil-rope 3in. in circumference weighs 13¼lb. per fathom, and is equal in strength to the old style rope 4in. in circumference and weighing 18½lb. The lock of the individual wires one into another is well shown by the sections exhibited. There are several stands of miners' tools, and Mr. Warsop, of Coniston, shows a hold-fast eyepiece with screw cone, for rendering picks and other tools interchangeable by expanding the shaft in the eye, and firmly holding it until the cone is unscrewed with a spanner. Miners' safety fuses and igniters are exhibited at two stands, that of Bickford, Smith, and Co. having a model showing the method of placing the igniters and fuses for firing several charges simultaneously. J. Buckton and Co., of Leeds, show a 50-ton testing machine, with their patent autographic indicator. At the time of our visit to this group several of the exhibits were still missing, or could not be found; but there is one which is sure to be seen by the visitor—viz., the patented machine of Scott and Hilder for separating iron filings. It consists of a rotating horizontal disc, fitted with electro-magnets, which are alternately magnetised and demagnetised by means of a commutator. Two endless belts run beneath, and the filings, being fed into a hopper, pass along the belts, the magnets picking up the iron filings when over one belt, and dropping them as they pass over the other. The two belts then throw them off into two bins for "iron," and "brass and refuse."



## THE AMATEUR WORKSHOP.—VII.

### Planing Machines.—Power Gear.

FROM the consideration of the hand-driven table we now pass to that of the multiple power gear. The Figs. 68, 69, 70 show a train of gearing adapted for the accomplishment of light work, strong, but not unwieldy. The wheels are of about the same size and pitch as those which are used for the back gear of lathes of 5in. or 6in. centres, and if such could be purchased of the makers, in sizes approximate to those figured, the labour of pattern-making could be saved. For the sizes of the wheels are not necessarily fast dimensions, but will permit of variation. Thus the return and cutting strokes are in the ratio of 2½ to 1, but the wheel C could be replaced by one having fewer teeth to give a ratio of 2 to 1, or by one having a greater number, to give 3 or 3½ to 1. The size of the wheel E could likewise be altered, either relatively to wheel G, or to the driving pulleys, and the rate of travel of the belt may be modified by altering the diameter of these, or the number of revolutions of the driving countershaft, or the diameter of its pulley. The pinions are not capable of much variation, since, if made larger, power is lost, while small pinions are driven with difficulty by their wheels, notwithstanding that they themselves will drive their wheels easily. The pulleys are made for 1¼in. belting, which is powerful enough for the work the machine has to do.

I have started with the assumption that the travel of the table is to take place at the rate of 15ft. per minute while cutting. The rate of cutting could be varied, however, if one class of work chiefly is intended to be done in it. For brass work the table could be driven faster, while for wrought iron its speed might be reduced, say, to 12 or 13, and these modifications can be made by the methods alluded to in the preceding paragraph—by altering the diameters of the driving or the driven pulleys, or the number of revolutions of the countershaft. Again, when the relative diameters of the pulleys are fixed finally, it is sometimes desirable to be able to drive at variable rates, and then, though the sizes of the direct driving pulleys remain unaltered, we can, by introducing speed pulleys overhead, upon the line shafting and the countershaft, get as many rates of travel as there are steps to the pulleys.

Returning to the figures, let us now see definitely what our train of gearing will effect.

A is the driving-pulley, 8in. diam., for forward or cutting stroke, B, first pinion for ditto, both of which are keyed on shaft *a*; C, first wheel for ditto; D, second pinion for ditto, both keyed on shaft *c*; E, second wheel for ditto, keyed on shaft *b*, which carries the rack pinion F.

Again, A″ being driving pulley for backward stroke, G is the pinion for ditto, working into the wheel E, and driving rack pinion F.

The list of wheels is therefore as follows:—

A, A′, A″ pulleys 8in. diam.
B, pinion containing 14 teeth of ⅝in. pitch
C, wheel " 35 " "
D, pinion " 14 " "
E, wheel " 51 " "
F, pinion " 11 " "
G, pinion " 14 " "

Having fixed on 15ft. per minute for cutting speed, we want to know the rate per minute at which the first shaft, *a*, must revolve to produce that effect. The two pairs of wheels, B and C, and D and E, will furnish us with the data for obtaining that ratio, and it will be—

$$\frac{C \times E}{B \times D} = \frac{35 \times 51}{14 \times 14} = 9{\cdot}1$$

That is, shaft *a* will make 9·1 revs. to one rev. of *b*.

The rack pinion F, measures 8¼in. in circumference at the pitch line. The number of revolutions, therefore, which the shaft *a* will make in one minute, the velocity of the table being 15ft., will equal—

$$9{\cdot}1 \times \frac{15' \times 12''}{8{\cdot}25} = 198{\cdot}4 \text{ revs. per minute.}$$

We have 8in. pulleys then, on the shaft *a*, to make 198·4 revs. per minute. If we assume that the countershaft makes 100 revs. per minute, the driving pulley upon that will have to be—

$$\frac{198{\cdot}4 \times 8}{100} = 15{\cdot}87\text{in. diam.}$$

These are our velocity ratios. The gain in cutting power simply, from the pulley A to the rack-pinion F would be

$$\frac{A \times C \times E}{B \times D \times F} = \frac{(8 \times 3{\cdot}14159) \times 35 \times 51}{14 \times 14 \times 11} = 20\ 80.$$

The gain in power in the return stroke would be

$$\frac{A'' \times E}{G \times F} = \frac{(8 \times 3{\cdot}14159) \times 51}{14 \times 11} = 8{\cdot}32,$$

and the ratio of the forward and backward speeds

$$\frac{20{\cdot}80}{8\ 32} = 2{\cdot}5.$$

I have struck the teeth of these wheels by means of Prof. Willis's odontograph scale, and in the case of each have also drawn three teeth to full size (Figs. 71, 72, 73). The directions given in the last article relative to the making of the rack pinion will also apply to the pattern of the pinions figured here, one pattern sufficing for the three castings. The two larger wheels, however, must be made in a different fashion. Figs. 74 and 75 show these in section. They are purposely drawn as light as possible consistently with strength, and the plated form is chosen as being simpler of construction than wheels with arms, and equally good for our purpose. If we describe the making of one of these patterns, therefore, those remarks will apply also to the other. The Fig. 76 shows the *pattern* wheel in section with the joints in detail. It is made as follows:—Get three strips of dry mahogany, each planed to 5/16in. thick, and large enough, when laid edge to edge to make a circle of 6¾in. in diam. It will really have to finish to 6½in. Screw them upon a true face chuck, not glueing the joints, but leaving them 1/16in. open. Glue a course of sweeped segments ⅝in. wide in the rough upon this plate, their outer edges being flush with the 6¾in. line. When the glue is dry, face over to a full ¼in. thick, and glue another similar course above this; the end joints in this last course to come midway between those of the previous one. Face this course to a distance of ½in. and 1-32in. measured from the plate. Turn the inner edges of the segments to the templet made from drawing, bore an inch hole through the centre of the plate, and by means of this hole rechuck against the side already turned. Build up two courses of segments upon the opposite side, turn their inner edges with the templet just used, then turn the whole width of the rim at once to 6½in. diameter, giving a very trifle of taper, indicated only by a tight and an easy fit of the calipers.

The outer diameter will then be pricked out by spring dividers into 35 divisions, and lines drawn across to these divisions with scriber and square. Each dimension will indicate the centre of a tooth; but it is immaterial whether the centre or the edge of the tooth be set to these lines.

The teeth are made in mahogany, and are worked in a templet box shaped like Fig. 77. The tooth stuff is first planed on one edge, and squared off to 1⅜in. lengths. These lengths are fitted and worked in succession in the space cut out in the block, a common round and rebate plane being used. Uniformity of shape and facility of production are thus secured.

When glueing the teeth on the rim, it is not safe to trust entirely for accurate results to the lines marked by the dividers and square; but calipers must be employed as a check while the glue is yet moist, and the teeth therefore being capable of minute adjustment sideways. A little cleaning up will be needed after the glue has dried, particles of worked out glue being removed with a chisel. Fine glasspaper will be applied to the tooth-flanks through the medium of a rubber, and the only taper needed in so shallow a pattern may be given by imparting slightly harder pressure on the lower than on the upper parts of the teeth. Two or three applications of shellac varnish will be beneficial in preserving the glue from the action of the moisture in the sand, and in imparting a smooth surface skin.

The bosses, *a a*, are turned separately, and held in place only with studs fitting easily into the central hole in the plate. An inch print will be attached to one of the bosses, and with this the pattern is complete. The wheel (Fig. 75) will be made in the same way.

The driving pulley (Fig. 78) is very light, as all pulleys ought to be, and that is a reason why especial care should be taken in making the pattern. Fig. 79 shows it in section as prepared for pulley A′. The bosses are studded on, as in the wheel just described, and there is another reason for this in this case, and it is that the bosses on the outer pulleys are different from those upon the inner pulley, A having a keyway boss, A′ having none, A″ having a special boss for the attachment of the pinion G. The very thin segments of which this pattern is composed must be made of mahogany, well jointed, and the best glue must be used, else the pieces will come apart very quickly. The rounding of the outside is better not done in the pattern, but a shade of taper should be given from the top to the bottom edges. Note also that ·1 in. of taper should be put upon the inner edges of the rim. By all means have the metal soft for facility of turning, for even soft metal cast so thin will become hardened slightly in casting.

We have to get our castings thus:—One off wheel C (Fig. 74), one off E (Fig. 75), two off pinions B and D (Fig. 80), one off pulley A′ (Figs. 78 and 79), perfectly plain; then one off same pattern for A (Fig. 78), with key boss ¼in. thick and 1¼in. long. Then one off same pattern with bosses altered to suit A″, in which pinion G, same pattern as B and D, is cast along with the pulley. Then one off rack pinion F (Fig. 70), described in the last article, having a boss cast on one side to bear against the boss on the bed.

The reference letters upon Figs. 68, 69, 70, to which no allusion has yet been made, have relation to details of the parts indicated, sketches of which will appear in the following article.

These castings are very light, wheel E weighing 11lb., wheel C 5½lb., and pulley A 6lb. About 15s. per cwt. will be paid for these.

---

# NEW AND LITTLE-KNOWN APPLICATIONS OF THE NITROMETER.*

By ALFRED H. ALLEN.

AS long ago as 1847 the late Walter Crum described a method of estimating the nitrates and analysing gun-cotton, which consisted in passing up the nitrated substance, together with some water and sulphuric acid, into a graduated tube filled with mercury. The nitric oxide liberated in the reaction was subsequently absorbed by a strong solution of ferrous sulphate. The method of manipulation was greatly improved by Frankland and Armstrong in 1868, and recommended by them for the estimation of nitrates in water. Their use of a tube open at one end and closed at the other by a tap surmounted by a cup greatly facilitated the introduction of the nitrate and acid. This apparatus, which may be called the Frankland-Armstrong tube, would have come into more general use had the agitation of the lighter liquids with the mercury been more easy to effect; but the accuracy of the results yielded by it have been fully proved by Mr. R. Warington, who also found that the presence of chlorides did not interfere to any notable extent with the amount of gas obtained.

Mr. G. E. Davis states that the idea of applying the mercury process to the assay of nitrous vitriol was suggested to him by Dr. John Watts in 1872; and, in a paper read before the Faraday Club on January 22nd, 1878, Mr. Davis fully described the use of the Frankland tube for the assay of vitriol, which tube he used in connection with a mercurial trough. In February, 1878, Mr. Davis informs me that he connected Frankland's tube to a piece of combustion tube by means of indiarubber tubing, and used the two side by side in a burette-stand. This arrangement constituted the first form of the instrument we now call the nitrometer.

The name "nitrometer" is due to Dr. Lunge, who in 1878 published and illustrated a description of his instrument.

To Dr. Lunge, then, belongs the credit of the first published description of the nitrometer, but the same instrument appears to have been devised independently at a somewhat later date by Mr. Campbell.

Lunge's nitrometer possessed one decided improvement in the use of a three-way tap, which arrangement appears to have been adopted from Bunte's gas apparatus. When the nitrometer is employed for the estimation of nitrates, or the assay of nitrous vitriol, the three-way tap greatly facilitates the removal of the acid liquid at the end of an experiment, without necessitating the complete emptying of the nitrometer.

As ordinarily employed, the nitrometer-stand is so arranged that the open or reservoir-tube must be removed from its position and brought into close proximity to the graduated tube before the measure of gas in the latter can be read off, and it is therefore an advantage to have the stand so constructed that the closed and open tubes of the apparatus, which I propose hereafter to refer to as the "nitrometer" and "reservoir" tubes respectively, should be in close proximity.

Another inconvenience attending the use of the nitrometer is the persistent mercurial froth which remains after the completion of the reaction, and prevents the reading of the level of the mercury in the nitrometer tube from being taken without delay. When great accuracy is not required, this may be avoided by employing a tolerably wide tube; but, for ordinary purposes, it is preferable to adopt a plan suggested by me in a paper on the estimation of nitrates by the nitrometer published in 1880 (*Analyst*, v. p. 181). In that paper I proposed to make a mixture of sulphuric acid and water, in the same quantity and proportions as the acid and solution of nitrate are employed in the nitrometer-tube, and to pour this mixture on the top of the mercury in the reservoir-tube. It is then possible at once to bring the aqueous liquids in both tubes to the same level, and the incomplete separation of the mercury from the aqueous liquid becomes a matter of indifference. In the same paper I propose to make an experiment with a second nitrometer, in which a definite amount of nitre was used. By noting the volume of nitric oxide evolved in this apparatus, and comparing it with that obtained in the case of the liquid of unknown composition, it becomes unnecessary to make any correction for pressure or temperature; and the standard quantity of gas, when once obtained, can be kept in the tube without alteration for any length of time. If this course be pursued, it is desirable to keep a little strong sulphuric acid in the cup to prevent any possibility of leakage.

Before leaving the question of the estimation of nitrates in the nitrometer, I may point out a source

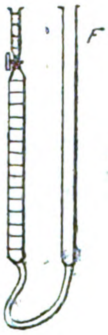


FIG. 1.

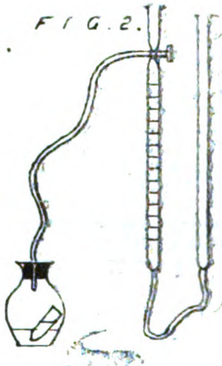

FIG. 2.

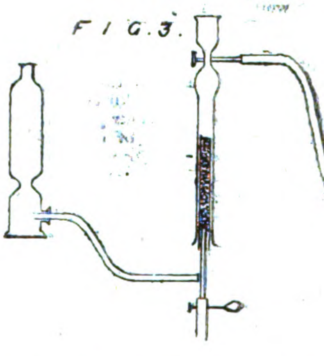

FIG. 3.

---

* Abstract of a paper in the *Journal* of the Society of Chemical Industry, No. 3, Vol. IV.

of error which appears not unfrequently to have been ignored. This is, that strong sulphuric acid has a notable solvent power for nitric oxide, and hence the full amount of gas cannot be obtained unless the sulphuric acid be diluted below that point at which its solvent power for nitric oxide becomes appreciable. Warington and Thorpe both recommend that the strong sulphuric acid and aqueous liquid should bear the proportion of three measures to two, and my own experience is in favour of this condition.

For the examination of dynamite and guncotton, Lunge places about ·35 gramme of the sample in the cup of the nitrometer, and dissolves it in 5cc. of concentrated sulphuric acid. The liquid is then allowed to enter through the tap, and is agitated with the mercury in the usual way. Probably better results would be obtained if a few centimètres of water were added after the completion of the reaction.

Hitherto all employers of the nitrometer appear to have regarded mercury as the only liquid with which the instrument could be filled, and of course this is actually the case in the estimation of nitrates, since the mercury itself takes part in the reaction.

For many purposes, however, the mercury can be conveniently replaced by a dense aqueous liquid, saturated brine being most generally suitable, and the following are some of the applications to which I have put the nitrometer when filled with such a liquid.

The assay of spirit of nitrous ether and kindred preparations for the proportion of ethyl nitrite is a problem which has engaged the active attention of pharmaceutical chemists. Hitherto the processes for the purpose have not been very satisfactory, the one giving results nearest to the truth being that of Eykman, which consists in treating the sample with a solution of ferrous sulphate and dilute sulphuric acid, heating the mixture, and collecting the nitric oxide gas evolved. Though the process is theoretically perfect, there are certain sources of error in practice, and the apparatus is somewhat complicated, and requires skill in management. Mr. D. B. Dott has proposed to estimate ethyl nitrite by treating it with potassium iodide and dilute sulphuric acid, and estimating the amount of iodine set free by titration with a standard solution of sodium thiosulphate. The reaction which occurs in this process is expressed by the equation:—

$$(C_2H_5)NO_2 + KI + H_2SO_4 = KHSO_4 + (C_2H_5)OH + I + NO.$$

In making experiments on Dott's method it occurred to me to measure the nitric oxide gas evolved, instead of titrating the iodine liberated, and as the reaction occurs completely and promptly at the ordinary temperature the nitrometer is an apparatus well suited for the purpose. I have now had a large experience in the process, which is best performed in the following manner:—A nitrometer should be filled with strong brine, and 5cc. of the sample to be tested should then be placed in the cup of the nitrometer, and allowed to enter through the tap, taking care that no air gets in at the same time. About 5cc. measure of a strong solution of potassium iodide is next allowed to enter, and this is followed by about 5cc. of dilute sulphuric acid. Effervescence immediately ensues, and, if the tube be vigorously agitated at intervals, the reaction is complete in a few minutes, when the level of the liquid in the two limbs of the nitrometer is adjusted, and the volume of nitric oxide gas read off. There is no difficulty in confining the reaction to the liquid in the upper part of the closed limb of the nitrometer. The nitrometer method has been proved to give very good results with pure sodium nitrite, prepared from silver nitrite, and employed in known amount, and may be advantageously used for the assay of commercial nitrite of sodium. With some specimens of sweet spirit of nitre a considerable volume of nitric oxide is produced, and iodine liberated before adding the acid, the reaction probably depending on the presence of free acid in the sample. The results obtained in the nitrometer are remarkably constant, and the method furnishes a very easy means of assaying sweet spirit of nitre with considerable accuracy, which is further increased if a correction of 1·5cc. of NO be made for solubility of the gas. The process does not occupy ten minutes, including the calculation, and actually measures the nitrous compounds present in the sample, instead of leaving their proportions to be inferred from a more or less complex reaction, such as the reduction of permanganate, &c. When strictly accurate results are not required, as is rarely the case in assaying such a preparation, the volume of gas need not be corrected for variations of pressure, temperature, and tension of aqueous vapour, &c. 1cc. of NO at the ordinary conditions of pressure and temperature corresponds to ·003184 gramme of ethyl nitrite,[*] and hence 5cc. of samples of spirits of nitrous ether of reasonably good quality evolve from 25cc. to 40cc. of nitric oxide.

Another useful application of the nitrometer is for the estimation of *urea* in urine. For this purpose the tube is filled with brine as before, and 2cc. of the sample introduced through the tap. This is followed by 10cc. of the usual solution of bromine in caustic soda[*]. Before the bromised soda has time to sink through the brine it comes in contact with the urine, and the great bulk of the nitrogen gas is liberated. By now placing a clip on the indiarubber connecting-tube and agitating the contents of the nitrometer tube vigorously, the reaction is completed, and the volume of gas may be read off. Not unfrequently the reading is delayed by the existence of froth on the surface of the liquid in the closed tube, but this may be instantaneously got rid of by introducing a few drops of alcohol through the tap. In some respects it is preferable to bring the bromised soda and urine in contact with each other in a small bottle or flask fitted with a perforated cork, and connected by narrow indiarubber tubing with the nose of the three-way tap of a nitrometer filled with brine or water (Fig. 2). A nitrometer is much better for this purpose than the device of a burette or graduated tube immersed in a tall jar of water, as is employed by Dr. Squibb and others.

The last arrangement is well suited for the estimation of *carbonates*, the sample being placed in the flask, and the acid for its decomposition contained in a small tube in the usual way. This amounts to a suggestion to employ a nitrometer in place of the measuring tubes of Scheibler's carbonic-acid apparatus. Of course the usual corrections for solubility of the gas in the acid liquid, &c., apply as much in one case as in the other.

The nitrometer may also be very conveniently used for the assay of commercial *peroxide of hydrogen*, for which it was first employed by Mr. G. E. Davis, who filled the nitrometer with mercury and operated on 1cc. of the sample, which he agitated with 5cc. of a saturated solution of potassium bichromate. Under these circumstances Mr. Davis found the peroxide of hydrogen to be split up into water and oxygen, the bichromate remaining unchanged, and this observation has been subsequently confirmed by Mr. W. H. Symons. It is usual to express the strength of peroxide of hydrogen in terms of volumes of oxygen obtainable therefrom, and hence the nitrometer is well suited for its assay.

According to my experience, the reaction of bichromate of potassium on peroxide of hydrogen does not occur so promptly or completely as could be wished, and I have therefore substituted for it an acidulated solution of permanganate of potassium. I prefer to operate as follows:—

The nitrometer is filled with a saturated solution of sodium or magnesium sulphate[†]. 1cc. of the sample is then introduced through the tap, and this is followed by a strong solution of potassium permanganate, which has been previously acidulated with sulphuric acid. The reaction occurs very promptly, and the permanent coloration of the contents of the tube suffices to show that an excess of the permanganate has been employed. When acidulated permanganate is used, the reaction is as follows:—

$$2KMnO_4 + 5H_2O_2 3H_2SO_4 = K_2SO_4 + 2MnSO_4 + 8H_2O + 5O_2.$$

Mr. Kingzett and other chemists have independently proved the truth of the equation by adding standard permanganate to hydrogen peroxide (in presence of free acid) contained in a Woulffe's bottle arranged so that the evolved oxygen could be collected and measured. The accuracy of the results obtained by permanganate was checked by estimating the iodine liberated by the hydroxyl from potassium iodide. Hence, when acidulated permanganate is employed for decomposing hydroxyl, only one-half of the oxygen gas liberated comes from the sample, the other half being derived from the reagent. Therefore, 1cc. of a sample of peroxide of hydrogen, described as of "10 volumes strength," ought to give 20cc. of oxygen in the nitrometer. If an acidulated solution of potassium bichromate be substituted for the permanganate, the reaction occurs very promptly, a double volume of oxygen being evolved; but for some unexplained reason the results are sensibly lower than those obtained with permanganate.

While the nitrometer is frequently used as an instrument in which to evolve and measure gas, it has not met with such a wide application as it deserves for the purpose of *absorbing* gases.[*] But, as a matter of fact, by the aid of two of Lunge's nitrometers, having their three-way taps joined by a short piece of indiarubber tubing, we can extemporise an apparatus for gas analysis capable of a variety of applications.

Having not unfrequently to make analyses of blast-furnace and Siemens gases for technical purposes, the importance of having a rapid and moderately accurate method of gas analysis has forced itself on my attention, with the result that I have devised a very simple apparatus for the purpose.[*]

Perhaps there is no chemical operation more difficult to describe than that of the manipulation with an instrument for the analysis of gases, but in practice the mode of using the apparatus in question will be found exceedingly simple, and to anyone in the habit of working with gases, means will readily suggest themselves for increasing the accuracy of the results.

In conclusion, I may call your attention to some qualitative applications of the nitrometer with a three-way tap, which instrument furnishes an extremely ready means of obtaining certain gases in a state of purity. For instance, if the lower end of a Lunge's nitrometer tube be cut off and the opening closed with a perforated cork fitted with a T-piece, one branch of which is closed by a clip and the other communicates with the reservoir, we have a convenient apparatus for generating at will small quantities of such gases as can be readily evolved without application of heat (Fig. 3). Thus, for example, if some granulated zinc be placed in the nitrometer and the instrument filled with water, on allowing acid to enter through the cup, hydrogen perfectly free from air will be evolved, and can be utilised in any manner desired by opening the three-way tap, to which a piece of indiarubber tubing has previously been attached. The T-piece at the bottom enables the dense solution of zinc to be tapped off when desired, and so the apparatus can always be kept full of hydrogen and in order for use. For small quantities of sulphuretted hydrogen the apparatus is also well adapted, and by means of the T-piece any choking up by ferrous sulphate can be wholly avoided. Carbon-dioxide also can readily be generated in the nitrometer tube, and if a small quantity of oxygen be required, as, for instance, in a gas-analysis, it can be obtained instantaneously and in a state of purity by the reaction between acidulated permanganate and peroxide of hydrogen. It is the three-way tap which renders the nitrometer suitable for a large number of the purposes suggested.

## HINTS FOR CLEANING BOILERS.

FOLLOWING the application of any boiler purger, or other substance for loosening scale or deposit upon the shell, heads, or flues of a steam boiler, special care and attention should be given to cleaning out the boiler, with a prompt removal of such loose fragments as may have become detached and fallen down. These particles, if not removed, are often swept about by the various currents within the boiler, and, collecting in a conglomerate mass upon some part of the fire surface, prevent access of water to that particular part, and thereby it is overheated and bulged—or bagged, as it is sometimes called—often inflicting a dangerous injury to the boiler and requiring a considerable outlay for new sheets, a patch, or perhaps other expensive repairs.

In the use of soda and other preparations used for the removal of boiler incrustations that are soluble in water, a separate vessel may be provided, suitably connected to the feed-pipe, so that the preparation, in its proper proportions as recommended, may be first dissolved, and, when properly prepared, fed into the boiler. When there is a heater the solvent may be prepared and emptied into that. Logwood or oak chips, leather clippings, and many other waste products of a manufacturing establishment that contain some useful ingredient, as tannin, soda, or starch, may often be used advantageously when they are recommended and their use directed by an inspector; otherwise serious difficulties may result, perhaps endangering the safety of the boiler. We have known silk fabrics and other delicately-fine articles to be ruined in the dyeing process by the too free use of boiler compounds, of which the users were ignorant in two essential particulars—namely, as to their composition and the safe quantity to be used.

The importance of knowing these particulars will be evident when we remember the great tendency of the boiler to foaming when purges are used, and the increased danger at such times of carrying over some of this water mingled with steam to the dye kettles, or wherever it may be used. We should not have a great deal of sympathy for the man who, declining to avail himself of the services and advice of a physician, ruined himself by dosing with all sorts of nostrums of which he was ignorant; but such a man, at the worst, can but ruin himself, while another who persists in dosing his boiler may not only lose his own life, but he may sacrifice many other lives in the same foolish way. We know of an instance in which a party who had some condemned bacon in his storehouse which he thought to use advantageously in cleaning and lubricating his boiler, he having somewhere read that grease was an excellent thing for the purpose. As he described it afterwards, the boiler turned nearly inside out, and he fondly hopes that he may live long enough to get even with the man who recommended it to him. Another case was that of a fireman, whose duty it was, under the direction of the engineer, to fire and keep clean a battery of boilers, who, happening to hear some of his mates say that oil was an excellent thing for softening scale, thought to make a trial of it on his own account. So one Sunday, when cleaning out his boiler, he went through the shops connected with the establishment and gathered up the refuse oil and grease from various drip-pans, securing in this way two or three gallons, which he poured into one of the boilers and afterwards filled it with water. Soon after the steam was got up the fire sheets became bagged and beautifully corrugated, and leaked like a sieve.

---

[*] I have had a special nitrometer (Fig. 1) constructed for me for the assay of nitrous ether preparations. The graduated tube holds 50cc. and the cup is narrow and cylindrical, and has marks at 5cc. and 10cc. above the tap. This arrangement renders the use of a pipette or other separate measuring arrangement unnecessary, as the cup can be filled to the 5cc. mark with the sample, and thus a definite amount taken for the analysis. In this case a three-way tap is of no advantage. Messrs. Cubley and Preston, of High-street, Sheffield, are now prepared to supply these nitrometers to those desirous of employing the process mentioned in the text.

[*] 100 grammes of caustic soda are dissolved in 250cc. of water and 25cc. of bromide cautiously added to the well cooled liquid. In some respects it is preferable to dilute the 10cc. of this solution with an equal measure of water before introducing it into the nitrometer.

[†] If brine be used there is a tendency to error from the evolution of chlorine.

[*] Messrs. Cubley and Preston are prepared to supply the apparatus for gas analysis described in the text.

In boilers under our supervision we have used crude petroleum many times for the purpose of loosening line scale, and with the most satisfactory results. We do not approve of the use of grease, and we deem the application of animal oils or fat to the interior of a boiler for that purpose as very hazardous. As a rule, when a boiler is in service, a systematie daily charge of a proper solvent, graduated to the capacity of the boiler, will be found more efficacious than a larger charge at longer intervals, and is less likely to cause foaming and kindred difficulties. An important matter sometimes overlooked is the need of regular times for it. When about to put a boiler out of service for a thorough cleaning, it will be found an excellent plan to let the boiler cool off gradually and the pressure fall slowly until it has reached about 5lb., when the safety valve may be raised and the remainder blown off. Run off the water and remove the hand-hole plates, when the scale will be found much softened and easily detached, while the deposit can readily be washed off with a hose. We have found this an excellent plan to pursue even in marine boilers using sea water and depositing a very refractory scale, as the North Atlantic or Gulf of Mexico. Blowing down a boiler between the limits of high and low water, or, in other words, between the upper and lower gauge cocks, is often very beneficial and assists materially in freeing it from the ill effects of scum and other impurities. If, however, this blowing down is not intelligently done there is a probability of great waste and serious loss; for in blowing out good water at the temperature of the steam pressure and replacing it by other water, perhaps of no better quality, at the much lower temperature of the feed, there is a great loss of heat and consequent waste of fuel. Blowing down a boiler can, however, under no circumstances be depended upon to thoroughly clean it and remove loose fragments of scale and much of the deposit commonly found. This can only be done by systematic periodical washing out at intervals to be determined by the circumstances of the case.—*Locomotive.*

## OLD AGE AND THE CHANGES INCIDENTAL TO IT.[*]

By G. M. HUMPHRY, M.D., F.R.S., Professor of Surgery at the University of Cambridge.

OLD AGE acquires a gradually increasing interest as advancing civilisation enables a larger number of persons to attain to it, and affords them additional means of enjoying it and profiting by it. We are, I think, too much accustomed in our ideas to limit the work of development to the periods of adolescence and maturity; and, indeed, the surpassing wonders of that work—I say surpassing wonders, for unquestionably the processes of development of an animal body are the most marvellous, the most mysterious, and the most interesting in the whole range of the physical world—are most fully demonstrated in the early periods of life. But they do not end in them, or even when the body has been brought to its fully matured condition. They continue in a definite and orderly manner, though with lessened and lessening activity, to the termination of life, at whatever period that termination may occur. The march of changing events in the human body, from the age of forty or fifty to one hundred, is as regular, as orderly, as developmental, though less quick, and therefore less apparent, as it is from birth to adolescence, or from conception to birth. It is one of the resultants of that inscrutable *vis*, call it what you will, and refer it to what you will, which makes all nature one, which determines the course and end of each animate and inanimate object, and by which, in the well-known words of Keble,

> "To its funeral pile this aged world is borne."

A main feature of the "ascending," if we may so call it, development, the development from birth to maturity, is an increase of material, an increase of activity, and an increase of strength—of passive or resisting, as well as of active, strength; and the main feature of the "descending" development, the development from maturity onwards, is a lessening of material, and lessening of activity, and a lessening of strength. In the normal "ascending" development, material and strength are added to the several parts of the body in due relation to their respective requirements, so that they may all grow on *pari passu*, and the proper harmony of proportion may be maintained between them; and in the normal "descending" development, the relative proportions of the several structures and organs are preserved, while weight, force, and activity are being lowered by gradual and well-adjusted diminution of material and of nutritive activity. During the time that the bones are becoming lighter and less capable of offering resistance, the muscles become, in like proportion, lighter and weaker, and with a narrowing range of action; and the associated volitional and other nerve-apparatus exhibits a corresponding lowering of energy and force. A time comes at length when, in the course of the descending developmental processes, the several components of the machine, slowly and much, though equally, weakened, fail to answer to one another's call, which is also weakened, when the nervous, the circulatory, and the respiratory organs have not force enough to keep one another going; then the wheels stop rather than are stopped, and a developmental or physiological death terminates the developmental or physiological decay. How much may those who pass gently into this natural or physiological death be envied by the many sufferers under the protracted and painful pathological processes which too often induce a premature extinction of life! The most distressing part of medical duty is the being called upon to witness, with the inability to arrest, the onward course of disease, such, for instance, as that of a slowly but surely growing cancer, boring its way into the strong and sturdily resisting frame; and the great hope and aim of medical study is to prevent such fatal interferences with the developmental processes, and to enable these processes to work out, in their own uninterrupted way, the quiet, easy, gradual method of dissolution. Yet, strange and paradoxical as it may seem, this gradual natural decay and death, with the physiological processes which bring them about, do not appear to present themselves in the ordinary economy of Nature, but to be dependent upon the sheltering influences of civilisation for the opportunity to manifest themselves and to continue their work. For the needs of the first, or infantile, period of helplessness Nature has made a sufficient provision in the parental instinct which protects and nurtures the young. But this lasts only so long as the requirement for it exists. It ceases as soon as the young has the ability to help itself; and it does not return and is not supplemented by anything of its kind. It gives way before that struggle for existence which is the engenderer of selfishness, dominating over all other impulses and shutting out all heed for the worn and weary, for the feeble and the decaying. These, being unable to help themselves, are crushed out by the various provisions which Nature makes for their destruction. The good result of this great seeming evil being that all in the natural, or primitive, animal world is in the ascendant to, or in the enjoyment of, bodily perfection. All teems with budding life or full health and strength. To falter is to fall; forasmuch as the first evidences of weakness and the beginning of decay arrest themselves by preventing the power of self-maintenance in the weak and the decaying. The same with disease. It, in like manner, stops itself. Indeed, it can scarcely be said to be allowed to enter into the pure realm of Nature. Sick animals are not there provided for, have no abiding-place there, and soon perish; so that there is no wasting and pining, no lingering fevers, no destroying cancers, no decrepit frames. Neither the bird that fails to elude the hawk nor the hawk that fails to seize the bird can long continue in existence. Thus, in the economy of Nature, death is swift, and comes early, as soon, at least, as failure of strength renders the animal unable to protect, or provide for, itself; and man, it would seem probable, had no exemption from this sharp, though, on the whole, beneficent law of animal life. In early times, when the race was to the physically strongest, when health, and strength, and activity were necessary to provide the hand-to-mouth means of sustenance, and to give defence, when men and animals were much on a par in this and many other respects, early death must have been the common fate, being brought about by climacteric agencies or by the tooth of the hungry beast, or by the hand of man himself. This, indeed, we still find to be the case among some of the rude race of mankind. But in man was the germ of a better order of things, the germ of sympathy with, of feeling and love for, others which was besides and above the mere parental instinct, and which was calculated to counteract and over-ride the selfish bent, and to raise man in this, as in some other respects, above the mere animal. It was not to be expected that this good seed should be without a blending with tares, and the scope thus given for the fuller development of the physiological processes, gave scope also for the development of the pathological processes, and enabled the various diseases to spring up and take their course, afflicting not man only, but those animals also which come under his fostering or protecting influence. It may therefore be said that the prolongation of life into and through the periods of decay and into and through the processes of disease—indeed, almost, if not quite, the very existence of decay and disease—is the result of human forethought and sympathy. In other words, decay and disease are, by civilisation, substituted for quick and early death. Without attempting to balance the *pros* and *cons* of this, we know it to be a position from which there is not, and ought not to be, any disposition to recede; and if there were the wish, there is not the possibility. The onward march of civilisation is a necessity, and the onward progress of disease will tend to go with it. But it does remain for forethought and sympathy to narrow the range of the evils they have themselves engendered, or which have sprung up with them; and it is pre-eminently the noble work of our profession to contribute to this—to weed out and check the growth of the morbid tares, and to help the good seed to grow on to its full harvest—to prevent, that is, the origin, and to arrest the advance, of disease, and to give to the body the best opportunities for health and longevity. The first requisite for longevity must clearly be an inherent or inborn quality of endurance, of steady persistent nutritive force, which includes reparative force and resistance to disturbing agencies, and a good proportion or balance between the several organs. Each organ must be sound in itself, and its strength must have a due relation to the strength of the other organs. If the heart and the digestive system be disproportionately strong, they will overload and oppress the other organs, one of which will soon give way; and as the strength of the human body, like that of a chain, is to be measured by its weakest link, one disproportionately feeble organ endangers or destroys the whole. The second requisite is freedom from exposure to the various casualties, indiscretions, and other causes of disease to which illness and early death are so much due. Now, in both these—notably, in the second—woman has the advantage over man, and she consequently attains to greater age. That this superiority is not entirely due to the comparative freedom from exposures and to the greater temperance in the woman, but is partly a result of a stronger or more enduring inherent vitality is shown by the fact that, even in the first year of life, when the conditions and exposures of male and female infants are the same, the mortality of girls is less than that of boys. A somewhat large number of boys are born, but they are more difficult to rear; so that the females soon gain the numerical lead, and maintain it, with almost steadily increasing ratio, to the end. This superiority may be to some extent associated with the less wear and tear in the smaller machinery of the woman's frame as compared with that of man; and one might expect that the small persons in both sexes would live longer than those of greater stature. This, however, scarcely seems to be the case. We find from our returns that the average height of the woman above eighty is about 5ft. 3in., which, allowing an inch for the shortening incidental to age, makes it to fall little, if at all, short of the average middle-age stature. The men also we find to be 5ft. 6in., which, making a corresponding allowance, gives them a good average height. It may also be observed, which we should not have expected, that the rate both of the pulse and respiration is quicker in the longer-lived sex; the average pulse in the woman over eighty being 78 to 79, while that in the men is 73; and the respiration in the women is 22, while that in the men is 18 to 19. It is a point of interest, in connection with the inborn or hereditary quality, that phthisis is reported to have appeared in some of the immediate relatives—father, mother, brothers, or sisters—of 82 of the 500 aged persons; in 51 of the relations of the 250 females, and in 31 of those of the 250 males. In the reports of some of these, it is stated to have occurred in several members of the family; and, in a few instances, the disease was manifested in both father and mother. It is evident, therefore, that the delicacy, or peculiarity, whatever it be, of constitution, which is associated with the tendency to the development of tubercle, is not only not incompatible with longevity, but is not unfrequently associated with it. No other special peculiarities have been shown in sufficient numbers to deserve notice here. The greater portion are reported to be of long-lived families, to have enjoyed good health throughout their lives, to have had good appetite and good digestion, requiring little or no medicine, to have been moderate or small eaters, to have taken little alcohol, and, commonly, not much meat; they have been good sleepers; and they show no traces of gouty or rheumatic affection in the joints of the hands. I have said that the main features in the downward, or senile, developmental process are a diminution of material and a diminution of force; and I apprehend that in the normal state it should be simply this—such a diminution, with, perhaps, a slight addition to the amount of oily matter naturally existing in the tissues; and that the other changes and degenerations that are incidental to age are no part of, but are rather to be regarded as deviations from, or morbid departures from, the natural phenomena. Let us consider the changes which take place in the skeleton, forasmuch as they are most appreciable, and, in many respects, the most interesting. The bones which, up to maturity, had been gaining in weight and size, now gradually loose weight, but do not ordinarily diminish in size, as they do in atrophy from paralysis; indeed, they not unfrequently rather increase in size from the continuance of a slow process of subperiosteal ossification. To this, in part, may be attributed the sharp outlines which the figure of old persons commonly acquires, except in the case of those who become corpulent. The absorption takes place first and chiefly in the more vascular and cancellous parts, the bony plates becoming thinned and removed, and the cancelli and the canals being enlarged and filled with marrow, while the bony tissue itself becomes often, though not always, more impregnated with oily matter. Hence, although the walls of the shaft are being gradually thinned from within, the ends of the bones are first and most affected, which explains the greater liability to fractures near the joints in old persons than in the middle-aged. This change, with the proportionate liability to fracture, is especially remarkable in the trochanteric and cervical parts of the thigh-bones, the strength of which is so much dependent upon the strength and disposition of the cancellous plates. This change takes place earlier in women than in men. The vascular and cancellous character of the alveolary processes of the maxillary bones renders these parts peculiarly liable to undergo wasting or absorption, causing the loosening and falling out of the teeth. This absorption of the alveolary processes and consequent removal of a part of the bodily machine which is in full and daily use is remarkable, though it has something of a parallel in the removal of another cuticular appendage—namely, the hair of the head. For the reasons I have given, it can scarcely take place in the condition of struggle for existence of the natural animal world, or in man in his primitive state; and it is accordingly commonly observed that the unearthed skulls of our early ancestors are well provided with teeth. The loss of teeth would imply a decay which the early man could scarcely have survived. What effect in more modern life this loss has upon the general health and the duration of the body is not easy to determine. It is often survived for many years; and it may be noted that, as before stated, it takes place more in women than in men, though they are the longer lived. Civilisation is doing something to supply the deficiency which it thus brings in its train by providing artificial substitutes; and they are at any rate free from some of the disadvantages, such as disease and decay, associated with the natural organs. It is remarkable how completely the alveolary processes become cleared away, so that scarcely a trace or them remains above or below; and the whole framework of the face, which ministered with them to mastication, is attenuated, and the body of the lower jaw is reduced to the narrow bar of its hard lower margin. At the same time, the resistance of the teeth being removed, the direction of the pull of the muscles upon the jaw is altered so as to open out the angle of the bone and bring the ramus and the body almost into a horizontal line. Thus the form of the lower jaw returns nearly to that of the infant. But there is this great difference, that whereas in the infant the bone consists mainly of the tooth-bearing or alveolary part, and the sub-alveolary portion scarcely exists, in the senile condition the latter only remains, the former having been cleared away. The changes which take place in the skull during old age are interesting. Commonly they correspond with those in the facial part, and the whole cranium becomes lighter and thinner, and therefore smaller. In some cases, however, it acquires an increase of thickness, by deposit of bone on the interior of the brain-case, and chiefly of the calvarial part, which seems to depend upon the lessened pressure there, and the consequent greater afflux of blood caused by the shrinking of the brain. The increase is usually most marked in the frontal region, which accords with the fact that the shrinking is most pronounced in the frontal lobes of the brain. The cartilaginous parts of the skeleton become somewhat thinner, which accounts for the loss of height in the aged; but I do not think that they usually undergo any other perceptible change in ordinary healthy old age. I have invariably found the costal cartilages soft in old people in whom I have had an opportunity of making an examination after death: the body of Old Parr, as described by Harvey, therefore presenting in this respect, as I believe, no exception to the general rule. And I regard the calcification of them to be a morbid rather than a senile change—a degenerative change to which the body is liable, as it is to cataract, bronchitis, and some other conditions, when it has passed maturity; and not one of the natural senile developmental processes. It may, I think, in like manner, be said, with regard to the calcification of the arteries, that it is the result of a morbid process intruding itself upon, interfering with, and arresting the normal progress of senile development. The rate of the heart's beats, according to our returns, does not vary much as age advances. From eighty to ninety it averages 73 to 74 in men and 78 to 79 in women. It is stated to be regular in 322 and irregular or intermitting in 85. The respiration in 110 returns of men between eighty and eignty-five averages 17 per minute. In 47 returns of men between eighty-five and ninety it averages 19 to 20; and in 16 returns of men at and over ninety it averages 23; in women it is a little quicker. Thus, in 86 returns of women between eighty and eighty-five it averages 22; in 54 between eighty-five and ninety it is also 22; and in 37 at and over ninety it is 23. It has to be borne in mind, however, that the not unfrequent occurrence of bronchitis in the aged raises somewhat the average rate of respiration in them. The failure of nutritive force in the brain manifests itself in the lessening of that power of concentration and quickness of attention upon which the sharp stamping of impressions and the ready recall of them depend; hence the memory for recent events is commonly impaired. The old man meanders on in his conversation unconscious that he is repeating himself; he remembers the tales of long past times, but forgets that he has just told them. This may go on to the condition of senile dementia. Happily, it does not often do so; and it is satisfactory to note how many of the very aged are in good possession of their mental faculties, taking a keen interest in passing events, forming a clear judgment upon them, and full of thought for the present and future welfare of others. It is no less satisfactory to find that the active, even severe and long-continued, functional activity of the matured brain seems in no way to impair its enduring qualities, and that good earnest useful employment of body and mind are not only compatible with, but even conducive to, longevity. After all, length of life is to be really estimated not by number of years so much as by good work done, not by the amount of time spent in the tame, fruitless manner indicated by the pithy words of Cowper—

> At morn she rose, at night she went to bed"—

nor by endeavours solely to advance our own fortunes, or reputation, or comfort, but by persevering efforts to promote the welfare of our fellow-men.

# SCIENTIFIC SOCIETIES.

## LIVERPOOL ASTRONOMICAL SOCIETY.

THE fourth session was closed on Monday evening by a meeting at the Association Hall, the Rev. T. E. Espin, B.A., president, occupying the chair. In a paper on "The Possible Origin of Comets," Mr. J. P. Sutton said the recent return of Encke's and Tempel's comets to our evening skies afforded an opportunity of considering what might have been their origin. The periodic time of Encke's comet had been observed to decrease by an average of about two hours in each revolution, and there could be no doubt that this would eventually land it on the sun's surface. The most natural explanation of this peculiarity was that some retarding influence gave the sun's attraction greater power than would otherwise be the case. The theory that comets had been erupted from the interior of planets was very ably argued by Mr. Proctor, but the only factors that could support such an hypothesis seemed to be that the aphelia of periodical comets crowd upon the orbit of Jupiter, and that the ascending node of Tempel's comet was very near to the orbit of Uranus. But the connection which we now know to exist in so many instances between comets and meteor systems was fatal to Mr. Proctor's view, because, if Tempel's comet was erupted from Uranus, so also must have been the meteor system to which it belonged. But he contended that no planet could by eruption generate a quantity of matter which would revolve in a continuous ring around the sun; in fact, he would point out that the enormous length of these meteor systems which form rings, unbroken perhaps throughout their entire length, quite precluded the idea that they could have originated anywhere within the bounds of the solar system. Whether they came to us from the stars might reasonably form a matter for dispute, though spectroscopic analysis certainly seemed to point to their formation by stellar processes. But certain it was that a sufficient retardation had been proved to render either the planetary capture or eruptive theories unnecessary for the argument.

Mr. W. F. Denning, F.R.A.S., would remind Mr. Sutton that the number of certainly known cases of identity between cometary and meteoric orbits was remarkably small, amounting, in fact, to only four instances. The connection between comets and meteors was proved rather by the precise agreement of their orbital character than by the mere number of such agreements. He thought, also, it was quite possible that comets might have a derivative source in planetary eruptions. A planet might, for example, have evolved a certain quantity of matter, in the form of an immense cloud of meteoric pellets (or, say, a volcanic outburst similar to the great Java eruption of August 1883), and this cloud would, if ejected with sufficient force to leave its parent planet, certainly tend towards the sun, and in process of time assume the form of a meteor ring. The foremost particles of the original mass would primarily gain ground on the central portion, and this would cause an extension of the stream. Then, as the mass passed perihelion, there would naturally be a slight difference in perihelion distance, and this meant a difference in periodic time. The mass would thus be resolved into a train of particles, and ultimately into one complete ring. Therefore, granting that comets and meteors had heen erupted from planets, their subsequent resolution into rings could only be a question of time.

Mr. Joseph Baxendell, F.R.S., &c., said Captain W. Noble had lately drawn the attention of the Royal Astronomical Society to an apparent discrepancy between the proportion of Saturn and his rings as seen in a telescope and those derived from data given in the *Nautical Almanack*. Since the publication of Captain Noble's communication it had struck him that a phenomenon he had witnessed in Oct., 1882, strongly supported the position Captain Noble had taken. At the date mentioned the outer minor axis of the outer ring had, according to the *Nautical Almanack* elements, become relatively less than the polar diameter of the ball; but he had observed the S. polar limb of the planet to extend sensibly beyond the southern edge of the outer ring, though no trace of the N. polar limb could be perceived on the northern edge of the ring. This appearance became well marked on the 28th October, when it was readily seen with a power of 180. As the elevation of the sun above the plane of the ring was at this time about 11½ minutes less than that of the earth, the invisibility of the northern limb of the planet could not have arisen from the shadow of the ring being thrown upon it. Assuming the elements in the *Nautical Almanack* to be correct, the only explanation appeared to be that the centre of the ball was not coincident with the centre of the ring system, but was at a sensible distance on the S. side, and, therefore, was not the centre of gravity of the planet.

Mr. R. C. Johnson read a paper by Mr. Geo. Knott, LL.B., &c., on the variable star U Geminorum. It was seldom the case that circumstances favoured the obtaining a complete observation of a maximum of Mr. Hind's remarkable variable star. In addition to cloudy skies, a further disturbing cause was to be found in the moon, whose path was comparatively near the star's place, and whose presence sometimes seriously interfered with, if it did not entirely prevent, all effective observations. The brightness of the star had been observed to vary from 14·5m. on the 1st of April, 1885, to 9·5m. on the 6th, when it slightly decreased in brightness; it reached its principal maximum of 9·2m. on the 8th. It would, therefore, appear that on this occasion the maximum was a double one, with a subsidiary minimum intervening—a phenomenon which had already been observed in maxima of this star. Professor Schönfeld had pointed out in his *Zweiter Catalog* that not only were the intervals between successive maxima of this star subject to great irregularity, but that the duration of the maximum phase (or length of time taken in rising to maximum and falling to minimum again) had a varying range of from 10 to 20 days. It would seem indeed that the maximum might be broadly divided into two types—one well marked with a duration time of 10 ± days, the other (not perhaps presenting quite such distinct characteristics, but still well marked) with a range of from 15 to 20 days. The longer maximum was sometimes marked by a slight subsidiary minimum. Whether the maximum was of longer or shorter duration the rise appeared to be rapid. He had not found any regularity of sequence as to long or short maxima, nor did there appear to be any decided relation between successive maxima and the lengths of the duration. Neither, on the other hand, did it appear that the point of magnitude touched was in either case higher or lower than in the other. But at the same time it must be admitted that the observations were hardly sufficiently complete to enable one to speak decidedly on points of this nicety.

The president read a paper on "The Probable Period of the Variable Star LL 14551." This star had been observed to be variable by him in 1883, and photometric observations of it were published in the *Monthly Notices* of the R. A. S., Vol. XLIII., page 432. During 1884 it had been observed with a photometer of his own contrivance, but only very casually, as the star was badly situated in our English sky. Mr. W. E. Jackson, of Constantinople, had, however, kindly taken up the observations, and, as an example of the magnificent opportunities enjoyed by astronomers in that part of the world, no less than sixteen complete observations were obtained last month, eight of them being on consecutive nights. From data that had thus been established, a period of 14·09 days was calculated. The photometric observations of 1883 also gave a similar period. The variation in light was very irregular. After a maximum the star decreased for 1½ day, the light then increased for about the same period, and, after remaining stationary for about 2 days, showed again a tendency to increase for 1½ day, after which it diminished, and then remained stationary, rising steadily for 2½ days before the maximum. As this was the first variable star known in this constellation, he purposed to call it R Puppis.

The Secretary read a paper, by Mr. J. Baxendell, jun., on "Transits of Jupiter's IV. Satellite." Attention had lately been drawn to the appearance of IV. as a dark spot when transiting the disc of the planet, and it might be worth while to submit a series of his observations of this phenomenon made with a 6in. refractor. On May 18, 1884, at 9.14 p.m., IV., and also the shadows of I. and II., were on the disc; IV. appeared as a dark spot, almost like a shadow, and nearly, if not quite, as dark as the shadow of I. The shadow of II. was not so dark, but more like Indian ink, and not more than one-third of the diameter of I. On Feb. 27 last, at 10.15 p.m., IV. appeared as a *very black spot*, much darker and better defined than the shadow of I. On April 18, at 7.50 p.m., IV. was observed not far from the *f.* limb, but not nearly so black as on previous occasions, though two hours later it was seen to be much darker; whilst at 11.15, when it was very near the *p.* limb, it was scarcely to be distinguished from the planet. Altogether, the observation seemed to confirm the statement lately made by Mr. Knobel, that IV. appeared much darker in the middle of its transit than when near either limb of the planet.

In a paper on "The Formation of Lunar Bays," Mr. S. E. Peal called attention to the shapes of Le Monnier and Fracastorius, which, he thought, seemed to show that they were the remains of circles once complete, and now probably de-formed by some influence of the adjoining mare which had bodily removed the plain from that side. Those who held that the bays were ruins of complete circles were, however, met by two insoluble difficulties: 1st, as to how such a huge circle could have been formed; 2nd, how so large a segment could have been so completely removed as to leave not a trace behind, and which, on the volcanic hypothesis, appeared to be impossible.

In submitting a voluminous report of the planetary section, Mr. W. S. Franks, F.R.A.S., said it contained a summary of the work done by members of the section during the recent opposition of Jupiter. No fewer than 185 sketches of the planet, many of them coloured, had been received, and some of them were exceedingly well done. The remains of the great red spot had received considerable attention, and dark transits of the 3rd and 4th satellites had been repeatedly noted. Other papers were read, and a motion to enable members residing at a distance to vote for the election of the Council was unanimously agreed to. Seven gentlemen were elected members, and Mr. W. S. Franks and Mr. J. E. Gore were elected associates of the Society.

## WESTERN MICROSCOPICAL SOCIETY.

THE monthly meeting of this society was held at the house of E. Bartlett, Esq., M.R.C.S., L.D.S., on the 4th inst. The subject was "The Human Lungs in Disease and Health"; on the table was an interesting series of illustrative preparations. Among them the host drew attention to a section of stonemason's lungs, and lungs showing carbon deposit from London smoke. Dr. Clippingdale exhibited a fœtal lung at seven months, with no air vesicles, and to all appearances perfectly structureless, with only a small supply of vessels. Under the microscope of Mr. E. Swain was a section of Sheffield saw-grinder's lung, the irritation from the steel gradually obliterating the lung structure and rendering it perfectly useless for breathing. Magnetic masks to arrest the filings are provided for the workmen, but very seldom worn. Mr. B. B. Woodward, F.G.S., showed Bacillus tuberculosis; Mr. Stokes, F.C.S., catarrhal pneumonia with thickened pleura and commencing cavity. Mr. S. P. Moore, B.Sc., a beautiful specimen of toad's lung injected. The next meeting of the club will be held on June 1st at the house of Dr. Foulerton (Pembridge Villas), who will demonstrate to the members a method of photographing microscopical objects.

## SCIENTIFIC NEWS.

THE death is announced of Mr. Robert D. Napier, the senior partner in the firm of Napier Brothers, the famous engineers, of Glasgow. David Napier, the father, was a pioneer in steam navigation, and the sons inherited his mechanical ingenuity. Robert has contributed many papers to the transactions of various societies, but will, perhaps, be best remembered as the inventor of the self-holding brake, and in New South Wales as the engineer who had charge of the dredging operations at Sydney harbour. Mr. Robert D. Napier, who died suddenly on the 8th instant, in his 65th year, devoted nearly all his spare time to mechanical and physical problems, and was an occasional contributor to our columns. Modest and unassuming, he was highly esteemed by all who knew him.

The death is also announced, at Göttingen, of Dr. Henle, the distinguished anatomist and founder of the so-called school of rationalistic pathology.

The Council of the Royal Geographical Society are making arrangements for holding in the Albert Hall an exhibition of articles used in the teaching of geography. The exhibition will probably be opened soon after the annual meeting, which will be held on June 8.

Lecturing last Friday at the Royal Institution, Prof. Burdon Sanderson gave a short history of cholera, and stated that those who resided in the west and north of London had little occasion for fear, even if the epidemic did appear in the East-end, and he ventured to predict that if cholera were about to attack London this year, it would long ago have been on the march.

Dr. Koch, who is one of the representatives of Germany at the International Sanitary Conference, recently attended a meeting of specialists on the cholera question, and reiterated, as the general results of his researches, that the comma bacillus manifests itself nowhere but in cholera cases, and is never absent from them.

At the meeting of the Physical Society, held on the invitation of the local Naturalists' Society at Bristol, a note by Prof. Ramsay and Dr. S. Young was read on Evaporation and Dissociation, in which they refer to the relation existing between pressure and temperature of certain dissociating substances. They hope shortly to publish full details of their experiments. Prof. S. P. Thompson exhibited and described a model illustrating the propagation of the electro-magnetic wave. The model consists of two sets of differently-coloured beads fixed to the extremities of wires, the beads being made by a mechanical movement to execute an approximately harmonic motion at right angles to the wires and the mean plane of the set. Prof. H. S. Hele-Shaw exhibited a self-recording stress and strain indicator, designed for one of Wicksteed's 50-ton single-lever machines erected in the laboratory of University College, Bristol. The stress is applied by moving a mass of a ton along a lever, which mass is connected by a cord with a vertical cylinder on the indicator. Horizontal distances are measures of stress, and vertical motions of the pencil indicate strains. The dimensions of the indications can be multiplied at pleasure by using a larger wheel for the wire connected to the pencil.

The annual reports of the Aëronautical Society of Great Britain for 1883 and 1884 have been issued in one volume, which contains several papers of interest. It can be obtained of Hamilton and Co., Paternosterrow. Mr. Brearey, the hon. sec. of the Society, will be glad to receive communications from those who are desirous of making a balloon voyage during the Aëronautical Exhibition at the Alexandra Palace.

The Rede Lecture will be delivered at Cambridge on June 2 by Mr. G. J. Romanes. The subject is "Mind and Motion."

At the April meetings of the San Francisco Microscopical Society, amongst the objects exhibited was a section of a malignant tumour by the president, Dr. S. M. Mouser. The section had been stained with carmine, and showed the unmistakable characteristics of the round-celled Sarcoma. Mr. Payzant, who is making a study of the life-history of Pulex irritans, exhibited specimens of the eggs and larvæ of the annoying insect. Mr. A. H. Breckenfeld exhibited Vol. I. of Cole's "Popular Microscopical Studies," consisting of twelve slides, each accompanied by a chromo-lithograph plate, and a pamphlet giving an elaborate description of the object. Samples of rich diatomaceous mud were received from Cuxhaven, Germany, and various parts of America. A paper on "Sarcoma" was read by Dr. Selfridge, and Mr. Banks exhibited a new class microscope by Messrs. J. W. Queen and Co. As a hand microscope, and for purposes of class demonstration, this instrument leaves but little to be desired. The method of illuminating opaque objects is very ingenious. The object slide is clamped by a novel spring arrangement to the base of the instrument, and as this base is hollowed out in the shape of a parabola, with a highly polished reflecting surface, all that is necessary is to direct the microscope towards a sufficiently strong light, the rays of which are then converged to a focus upon the object by reflection from the parabolic surface.

"Polarised Light as Applied to the Microscope" is the title of an interesting paper read before the Hackney Microscopical Society by Mr. E. A. Holmes. The author states that the idea some entertain, that the colours seen with polarised light are pure and unmixed, is a mistake. The colours, however vivid and brilliant, are always a mixture.

At the fortnightly meeting of the Edinburgh Medico-Chirurgical Society, Dr. Foulis gave a demonstration of the circulation in the web of a frog's foot and of some botanical test objects by means of the oxyhydrogen light. The light, transmitted through a powerful condenser, passed through an ordinary microscope lens, and was thrown upon a large plate of ground glass at a distance of about 25ft. The image of the object demonstrated could be focused on this plate with great exactitude, the definition even with high powers being excellent, and the general effect strikingly satisfactory.

The conversazione of the President of the Institution of Civil Engineers will be held in the International Inventions Exhibition, South Kensington, on Friday, June 5.

Experiments with the Phelps method of telegraphing to and from trains in motion, which we described on p. 25, continue to be made with satisfactory success; but we learn now that Mr. Edison has a method which dispenses with the insulated line between the rails. According to the report, Mr. Edison says: "By putting up this tinfoil-covered board lengthwise on the top of each car I can catch a message from the wire strung on poles 35ft. off, and can fling an answer back to the wire. It requires no change in the wires of any sort. The secret of it is in the machine for transmitting. When I was investigating what I called the 'etheric force' a few years ago, I accidentally discovered certain curious properties of static electricity. These I have now applied. The process is very inexpensive, as three men could equip a road 300 miles long for 1,000 dols. in three or four days. It seems certain that its adoption will be general, so that every train will be run from headquarters and every passenger will be accessible to his friends."

Thirty-four electric-light towers are, it is stated, to be erected in New Orleans.

Reichemberg's system of telegraphing and telephoning on the same wire simultaneously has, it is said, been tried with success between Madrid and Toledo.

The French Association for the Advancement of Science will this year meet at Grenoble on August 13, Prof. Verneuil being the president.

A translation has been issued of a lecture delivered at Coblentz by Capt. Callenberg, of the Rhenish Field Artillery, on the wire system (Longridge's) of manufacturing guns, in concluding which the lecturer said: "Let us not, therefore, like the English Ordnance Committee, rudely repulse the hand which is held out to lead us a step forward on our way, but rather let us make a trial." Experiment is the foundation of progress.

Messrs. Chittenden and Cummins, in the *American Chemical Journal*, describe their experiments to determine the relative digestibility of various food substances. They used artificial gastric juice, prepared with hydrochloric acid and pepsin, and putting the digestibility of beef at 100, they give the following figures for the other substances named:—Veal, 95; mutton, 92; chicken (light meat), 87; ditto (dark meat), 84;

salmon, 92; mackerel, 86; haddock, 82; trout, 78; lobster (young), 88; ditto (large female), 79; ditto (large male), 69; fresh cod, 72. Generally the white flesh is more digestible than the dark, and raw meat than cooked.

With reference to our notice of Miss Ormerod's report on injurious insects, p. 228, it may interest readers to know that "Notes" in a condensed form, with illustrations, are available for all who are anxious to spread a knowledge of these common and yet little understood facts of natural history. No. 3 is a brief account of the Ox warble fly, and we venture to think that if it were widely distributed amongst cattle rearers and daity farmers, it would help materially to stamp out the pest. Copies can be obtained free by addressing Miss E. A. Ormerod, Dunster Lodge, Isleworth.

# LETTERS TO THE EDITOR.

◆

*[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]*

*All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

*All Cheques and Post-office Orders to be made payable to* J. PASSMORE EDWARDS.

⁂ *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

**"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks a vice from whence great inconveniences derive their original."**

## ZETA HERCULIS—DARK TRANSITS OF JUPITER'S SATELLITES—THE SEPARATION OF DOUBLE STARS — EVOLUTION — THE STORY ABOUT THE STORES — MATHEMATICAL ASTRONOMY—TELESCOPE FOR OBSERVING JOVIAN PHENOMENA — LEGAL — POCKET TELESCOPE — POWERS OF OPERA-GLASSES—THE RESULT OF THE RECENT MEETING OF THE ROYAL ASTRONOMICAL SOCIETY—MERCURY IN THE SOLAR DAY-GLOW—THE NEW TIME—APPARENT ENLARGEMENT OF CELESTIAL OBJECTS NEAR THE HORIZON—TRESPASS—THE HELIOGRAPH.

[24249.]—I SHOULD like to add to what I said (in letter 24196) on page 211, that since replying to "Beta" there, I have examined ζ Herculis, with the result that with a power of 400 on the 4½in. Dallmeyer object-glass of which I spoke, and which is of the highest excellence, I wholly failed to divide the star. Hence I can only come to the conclusion that your correspondent must be labouring under some curious mistake as to having recently seen it double with a smaller aperture than mine. I hardly like to suggest the possibility of "Beta" having got hold of the wrong star. I should, by the way, like to ask Mr. Sadler whether the distance he gives in letter 24226, p. 233, is from calculation or from actual observation?

Mr. Bone (letter 24197, page 211), should read page 167, et. seq., of the last edition of Webb's admirable "Celestial Objects for Common Telescopes."

Some of the difficulties whose solution is sought by Mr. Nelson, in letter 24201 (page 212), have their origin in the fact that, as I endeavoured to explain some four years ago in these columns, separating power is a function of aperture (letter 18314, Vol. XXXII. page 494), and that the larger the object-glass the smaller the discs of stars become, and consequently the wider apart they seem. Bear in mind, then, that if the object-glass does not split a close pair of stars, no amount of magnification subsequently by the eye-piece will divide them; though, of course, if they are so far separated by the objective as to be just in contact, they may appear like a single object with a low eye-piece, while a higher one will sufficiently enlarge the image to enable its duplicity to be observed. I must repeat, though, that press deep eye-piercing as we may, we shall always have our stars in contact. To show how the aperture of the object-glass acts, we will take Mr. Knott's measures of the discs of three stars with a power of 368, and with various apertures of the objective:—

| Star Observed. | Diameter of discs as measured with the various apertures. | | | | |
|---|---|---|---|---|---|
| | 6·00in. | 4·95in. | 4·00in. | 3·00in. | 2·00in. |
| α Tauri.... | 0·846″ | 1·047″ | 1·398″ | 1·772″ | 2·608″ |
| Polaris..... | 0·929 | 1·130 | 1·395 | 1·729 | 2·378 |
| α Orionis .. | 0·852 | 1·214 | 1·683 | 2·162 | 2·932 |

The ordinary formula for separating power $\frac{4{\cdot}56''}{\text{aperture in in.}}$ presupposes that the compound stars are both of the 6th magnitude. Other considerations come in, in the case of stars like Polaris, in which the glare of light of the primary, with a low power, prevents the eye from readily catching so minute a point as the *comes*, when involved in it. Many minute stars are only visible with the highest powers that can be employed. This possibly has its origin (or part of it) in the fact that high magnifiers darken the sky without making a corresponding reduction in the light of these all but invisible objects. I do not see my way to any trustworthy formulæ such as Mr. Nelson asks for. To give a single illustration why: Blue stars remain visible when red ones of the same magnitude can by no artifice be seen.

Does not "Pre-Adamite" (letter 24202, page 212) see how naively he begs the entire question by his allegation that the seal and whale are distinct creations. Who told him so?

In connection with Mr. Dickson's letter (24217, page 218), I will now say that, as a shareholder in the Army and Navy Co-Operative Society, I was extremely surprised to read the letter (24163) of your excellent correspondent, "Montmartre," and the advertisement which appeared on the front page of No. 1048 of the ENGLISH MECHANIC. I candidly confess that I looked forward to a "row" at the next meeting of the society.

"Another Amateur" (query 56511, page 222) must be a little more precise in his definition than merely to employ the phrase "the higher parts of astronomical science." Assuming him to possess a competent acquaintance, though, with algebra and plane trigonometry, he may go on to read Todhunter's "Spherical Trigonometry," and the same writer's "Differential" and "Integral Calculus"; Puckle's "Conic Sections," Newton's "Principia," Godfray's "Lunar Theory," and Chauvenet's "Spherical and Practical Astronomy." This will suffice for some time to come.

"E. B. F." (query 56521, page 222) may observe the transits of Jupiter's Satellites capitally with a 2½in. object-glass and a power of 100. It seems an extraordinary thing that he has never attempted to make the experiment for himself.

The best books for "T. G. T." to get (query 56529, page 223) are "Stone's Justices' Manual," published by Shaw and Sons; "The Justices' Note Book," by Mr. Knox Wigram, published by Stevens and Sons; and "A Digest of the Law of Evidence," by Mr. Justice Stephen.

"Devoniensis" (query 56534, page 223) can only increase the amount of light in his telescope by lessening the power; and that at a cost wholly disproportionate to the total value of the instrument.

And in answer to his succeeding query (same page), let him point his opera-glass to a brick wall at such a distance that the rays from it are approximately parallel, and look through the glass at the wall with one eye, and at the wall directly with the other one. Then if one brick, as seen in the opera-glass, covers four as seen by the naked eye, the power is four, and so on. A divided scale affords a more refined mode of measurement.

I do not think that the Fellows of the Royal Astronomical Society, upon whose requisition the special meeting was held on the night of the 8th instant, have much reason to complain of its result, inasmuch as they succeeded in carrying, by an overwhelming majority, a motion which will practically enfranchise every one entitled to be addressed as "F.R.A.S.," be he resident where he may. In view of the frank way in which the memorialists were met by such of the Council as were present at the meeting, it may possibly have struck some of those present that the boon—or, rather, right—which they obtained for themselves might easily have been granted a little sooner, without having the necessity for it forced upon our rulers at all; but we will charitably suppose that the Council wished to ascertain most thoroughly the feeling of the Fellows generally in this matter before themselves stirring in it. On the question of voting by proxy at annual and special general meetings, the Fellows present were much more equally divided, and the motion for it was lost by a very small majority. Perhaps, after all, this is not an unmixed evil, inasmuch as there will always be people in every society who like to be thought for, and who would have posted their proxies to the Council to do as they liked with. The meeting was, on the whole, very good-tempered.

One thing came out pretty plainly in the discussion, and that is that our antiquated by-laws sorely needed revision throughout. For example, by-law 3 requires remodelling entirely, inasmuch as its spirit is annually systematically evaded. So, again, with by-law 12, which makes an "insufficient" balloting-list invalid—in other words, refuses to suffer a Fellow of the Society to give fewer than 21 votes! That a *redundant* list should be null and void is only common sense; that one allotting votes to such men only as the voter approves of should be rejected, is downright indefensible nonsense. So, again, with by-law 53, which recites, with reference to special general meetings, that "a week's notice shall be sent to every Fellow residing in or near London." Well, this dates from April 6, 1831, and the first railway out of the metropolis, that to Greenwich, was not opened until December 14, 1836; so that our fathers and grandfathers had to come into the metropolis by what were called "stages," or stage-coaches. Now that a man can run up from Brighton in about the time that it then took to get from a northern London suburb, this "near London" restriction is simply ridiculous, and as gross an anachronism as a doublet and trunk hose would be. I have selected three instances only; but these will amply suffice to support my contention that the time has arrived when a revision of our bye-laws is called for. Will our Council themselves summon the next special general meeting for this purpose?

I have to thank "Garrison Gunner" (letter 24225, p. 233) for the courteous and friendly little paragraph with which he concludes. It is satisfactory to find that we have the *intellect* of the Society with us, at all events.

I was very much interested in learning from letter 24223, p. 233, that Mr. Clapham had succeeded in observing Mercury during his recent eastern elongation, because I tried in vain myself to do so.

Let me thank "Civicus Olim" (letter 24247, p. 238) for kindly doing the work of the printer's "reader," and correcting the typographical error of "of" for "from," which appeared in the communication on which he comments. And, having done so, I may perhaps be allowed to add that I have never said one word about a *striking* clock; and am quite with your correspondent as to the grave difficulty which would arise from an attempt to discriminate between 22 and 23 strokes on a bell by anyone who had nothing but his ear to guide him. If, however, we are always to listen for the time, instead of looking for it, surely two bells would meet this difficulty; one upon which all hours up to 10 should be struck, and which should thenceforth give one stroke for ten, a bell tuned a third or a fifth higher, being employed for (so to speak) the units place of the hours. The endless confusion of which "Civicus" speaks would possibly exist for a week or ten days at the outset; after which, I must repeat, every one would wonder how he had been content to go on all his life in the present cumbrous and unscientific fashion. If "Civicus Olim" can devote a day to hunting up eighteenth-century literature at the British Museum, on the change of style in 1752, he will find that considerably stronger arguments than he employs were then used to show why such change might, could, would, and should, never be made. "Stare super vias antiquas" is an excellent motto; but it is one which is not of universal applicability. There is something very naïve in the *Civici quæstio* anent "Bradshaw," "Would it be used and sold, as it and other railway guides are, if so misleading?" Simply remarking that my accusation was that it was difficult to understand, and not that it was "misleading," I would reply Yes! of course it would—if it was the best and most intelligible one procurable.

Mr. J. W. Frazer (query 56613, p. 244) will find the paper by M. Stroobant, from which I quoted, in the number of *Ciel et Terre* for the 15th of February in the present year. The price is only half a franc in Brussels, where it is published. It ought to be procurable of one of the French booksellers in London for 6d. or so.

The only trespass committed by "Ento" (query 56614, p. 244), in rambling over private land in search of natural-history specimens is a civil one, for which the owner's remedy (if any) is an action at law. I am, of course, assuming that your correspondent breaks or damages no hedge or fence in getting on to his happy hunting ground. If he does such mischief, even in the smallest degree, he renders himself liable to a penalty of £5 (over and above the amount of the injury) under 24 and 25 Vic. c. 97, s. 25. Of course he may find his way into some strictly preserved cover, or among a congeries of rabbit burrows, and if a hard-swearing keeper can get the magistrates to believe him, may be fined £2 for trespassing in the daytime in pursuit of game. The legend so often seen on a board, "Trespassers will be prosecuted," is the merest *brutum fulmen*.

"Magister Artibus" (query 56628, p. 244) should invest threepence in the "Manual of Instruction in Army Signalling," published by Clowes and Sons, and obtainable at any of the military booksellers. He will find a description both of the heliograph and of the signals (which are dots and dashes) both in it.

**A Fellow of the Royal Astronomical Society.**

### DOUBLE STARS—γ LEONIS, &c.

[24250.]—Although Mr. Sadler will no doubt supply Mr. Holmes (letter 24199) with the information he requires, I inclose a few measures of the stars he mentions, in the hope they may prove useful. They are the mean of a series of measures made during the present season with my own instrument and an 8¾in. equatoreal belonging to a friend; and give for γ Leonis P.A. 112·5° and 54 Leonis P.A. 104·3°. I think any slight discrepancy in position angles may be reasonably referred to the atmosphere, which has been unusually unsteady of late. In fact, to obtain reliable measures has been a task of extreme difficulty, and I have little doubt the above are open to correction, but they are the best I have been able to obtain.

I do not know the date of the measure of 54 Leonis given in Webb, but it very probably is taken from the "Cycle." With regard to Cor Caroli, I am not aware that any very decided orbital motion has been detected either in distance or angle.

**Kenneth J. Tarrant.**

Letchford House, Pinner.

### A CHEAP TELESCOPE STAND.

[24251.]—I think H. Ritchie (letter 24228) will readily perceive that any deviation from the perpendicular in the axis of the telescope stand will necessitate an inclined floor, as the mirror end of the telescope will move in a plane parallel to that on which the axis turns; so that if the floor were horizontal and the axis inclined, the movement of the telescope in azimuth would be interfered with.

The equatorial mounting of the Newtonian telescope has the inconvenience of turning the eyepiece in inconvenient positions. This is remedied in the cylindrical metal bodies by causing the top of the telescope with the eyepiece and flat to revolve, so that the eyepiece may be conveniently placed in all positions of the telescope. The great convenience of following a star with one motion of the telescope is only to be obtained by an equatoreal mounting. But I hope, in the stand I am now making to carry my 15in. Calver mirror, to give to the telescope the two motions requisite to follow a star by the bladder clock, each to be carried by the telescope—the one for altitude to be fixed to the lever by which that motion is given to the telescope, and close to the front of the post; the other for azimuth to be fixed to the fast-and-loose lever, and carried by an extension of that lever behind the post, both motions being regulated by tubes from the two bladders fixed conveniently near the eyepiece. Thus I hope to make my new stand perfectly convenient.

**Philip Vallance.**

### CHEAP SET OF RESISTANCE COILS, WHEATSTONE'S BRIDGE, &c.

[24252.]—Seeing that I laid no claim to the particular form of Wheatstone's bridge, described by me in the issue for May 8 (which, by the bye, is illustrated and described in that well-known work "Magnetism and Electricity," by F. Guthrie, at p. 222 of the 1875 edition), I am rather puzzled to account for the *raison d'être* of Mr. J. Edgington's remarks (letter 24233).

I may, however, mention that having often, as a young student been precluded from obtaining necessary apparatus by the fancy prices put upon such articles, I have felt it almost a duty and always a pleasure to point out the way to the beginner how to procure or how to make any piece of apparatus which lay really within the powers of an amateur. It is for this reason I wrote the articles on "Resistance Coils," on the "Construction of Spectroscopes," and on the "Dynamo."

I would also mention that on examining the lists to which I am referred by Mr. J. Edgington, I find that even in this "cheap" set, the bridge is priced over 20s. If my friend will turn to my advertisement in the Sixpenny Sale Column he will find I furnish these bridges, with contact spring and ten binding screws complete for 5s. **S. Bottone.**

The Limes, Stanley-road, Carshalton.

### SHRINKAGE OF PAPER.

[24253.]—The difficulties referred to on p. 245 can, I think, be entirely overcome by a system we have adopted for many years past—i.e., all drawing paper is ruled with very faint lines to either ¼th or ⅛th inch scale, and the drawings are made to correspond with these lines. Whatever the alteration in size or form of the paper the variation in any square of ¼in. or ⅛in. is a matter of no importance, and the drawing and scale both being on the same base, a ready and certain means of correction always exists. **T. F.**

### COMPARISON OF TIDES.

[24254.]—A review of atmospheric conditions which have operated in producing the various changes of sea-level throughout the month of April shows a prevalence of anticyclonic pressure during the early part of the month, followed by stationary weather afterwards. Subsequently, a succession of anticyclonic disturbances until the 20th caused the intense cold which has characterised the spring season, and not until the end of the month have south-westerly winds prevailed. The tides, it will be noticed, have coincided more accurately with the predicted height than has been the case for some months past.

**James Pearson, M.A., F.R.A.S.**

Comparison of Tides at Liverpool and Fleetwood for the Month of April, 1885.

| Date. | Calculation. | | Observation. | | Error. | Barometer | Wind. | Remarks. |

### MYSTERY GOLD.

[24255.]—"Nun. Dor." (letter 24232, p. 234), asks if this alloy has ever been used for imitation sovereigns. It is not at all likely to be successfully used for this purpose, owing to its extreme lightness as compared with standard gold; the detection would be easy. An alloy of platinum with a small quantity of copper, and also platinum alone, heavily gilt, are both used for making imitation sovereigns; and I have seen imitations of most of the gold coins of England, France, America, and India made in this way. They are correct in weight, ring fairly well, and are practically impossible to detect until the gilding is worn off. The profit on the difference in value of the metals used as compared with gold is large, and there is no risk whatever in passing them, as they could not be detected so long as the gilding remained perfect.

**T. F.**

### EVOLUTION.

[24256.]—In letter 24202, "Pre-Adamite" seems to be perplexed when he asks, "What reason is there to suppose that a fossil creature, half-bird and half-lizard, or other recognised intermediate link, is so in reality? Why should it not have been purposely created in that form?" He fails to recognise that the supposed intermediate form may have been a connecting link, even though it may have been purposely created.

The subject of evolution recurs at intervals in your correspondence columns, and since in the form in which it is usually presented and discussed, the controversy leads to no definite conclusion, but brings the disputants back to where they respectively started from, I would like, with your permission, to present it to "ours" on what I consider is its true basis, though to some it may appear a novel one. To begin with, it is necessary to define clearly the rival theories. *Evolution* means the gradual evolving or unfolding of latent qualities, either physical or mental.

*Creation* means the coming or bringing into existence of such qualities previously non-existent even in the latent state.

It cannot be conceived that the simplest organic form could possibly have held latent within it the diversified organic characteristics, physical and mental, which are now existent between the amœba and man; and so it is held creation must have intervened. But admitting creation, it is not necessary to believe that it operated spasmodically by fits and starts. More likely its operation was slow and gradual, and the links which perplex "Pre-Adamite" may have been "so in reality."

Darwin has shown how, by the struggle for existence and survival of the fittest, the chain may have been indefinitely linked together. His theory is built on the principle of heredity—that the offspring retains the characteristics of the parents, subject to reversion to ancestral types, which latter point may be here dismissed. But he stipulates also for a condition which cannot be reduced to any law, inasmuch as it is capricious in its operation, and can neither be foreseen nor foretold—a condition, nevertheless, of such importance that he over and over again asserts in his works that without it his theory of natural selection is impossible. This condition, which is quite independent of natural selection, is that the offspring may differ from the parents not only as a reversion, but also in some new direction previously non-existent, and that this new character may be propagated. The appearance of such new and previously non-existent character comes within our definition of "creation," and can be explained in no other way. Regarded in this light, all organic nature bears the stamp of creation at every step, and Darwin has done good work in showing that these creations have not proceeded, as was at one time supposed, by violent leaps and bounds from one form to another very different from it, but that they have been brought into existence by slow and insensible processes less repugnant to our ideas of nature as we are able to judge of it. Evolution alone, without creation of new forms, could not account for progressive development.

The loss of members from disuse, and their appearance finally as rudimentary organs, is outside the main issue here dealt with, since they are traceable to pre-existent forms, and do not explain the appearance of what did not before exist.

**H. B. F.**

### EVOLUTION.

[24257.]—I have to thank two correspondents for information supplied in answer to my query, which query was an honest, not a captious one—as I am not opposed to the theory of evolution, nor is it my purpose to support that of independent creation. I am far more disposed to the idea that the truth lies in a combination of the two—that the Creator made a few typical forms of fish, bird, and mammal, and, compared with what we now have, only a few, which, owing to climatic and other geological changes, may very likely have ramified and branched out into the countless variety of the present race of creatures. My query meant to ask in reference to this: "Was the half-lizard, half-fish one of the few original creatures, or is it evidently and unquestionably an intermediate link?" If all creation—I must use the word for want of a better—sprang from protoplasm, then to my own uninstructed mind the puzzle of animal life is far greater than if I suppose a Creator's hand making a few typical creatures called beast, fish, and fowl to fly above the earth—called thus because the writer at that date was surrounded by creatures known by such names. It is the development of one of these three typical forms from the other that I always stick at, as, *e.g.*, the mammal from the fish as stated in "Crumby's" letter. True, there is the spine, and its processes, rays, or ribs ready made; but although a fin *might* become a leg and a spiny tail drops its fan-shaped extremity, I can get no further. The bony structure may possibly develop, but the *mammæ* whence and how? Surely, if a fish's surroundings were changed, the fish would die instead of accommodating itself to them? However gradually we dry up the pond, at last the time comes when the fish's surroundings become unbearable, and Nature yields up the struggle. I certainly can grasp such a development as that of a seal to a walking mammal, because it is already fairly at home on land, and its flappers might in the course of ages further develop if the water of its home so far diminished as to compel it to attempt, to a still further degree, progression on dry land. But here we have the mammæ, and the change is not so stupendous; but go back a step to fish with gills, and no such mammæ—fish whose youngsters never needed such motherly appendages, and there necessity compels me to draw the line. Again, in reply to "Rex," is it not possible that we are advancing backwards—that the rudimentary pelvis is not a remnant, but an embryo—that the seal and whale are becoming terrestrial mammals as I have suggested in the case of the seal? Does not the tadpole teach, in its development, extending over a few days and weeks, what is going on, on a larger scale—that the whale, if developing at all, is to become a dry-land animal, and not as "Rex" supposes? I do not hesitate to acknowledge the difficulty even of a theory of a primal creation of the three typical forms of mammal, bird, and fish; but it appears to me a simpler one than others. As to the insect world, it is not even named or intimated by the writer of Genesis, which is at least strange, as is also his statement that fishes and birds both originated in the water. Is anything suggested here in reference to the development theory? I do not hold on to the skirts of that writer, who evidently wrote unscientifically of what he knew as bird, beast, and fish; but if there was an ark and a flood, that ark could have contained perhaps the *then* birds and beasts, few in number, which answered to those simple types. I can imagine, for example, one ancestor in common of leopard, tiger, cheetah, puma, and, maybe, lion of our own times—one ancestor of the whole tribe of Felis, or Canis, or Equus, and for these there would have been room; but I care little to prove it—only I thus get back to the ancestral created type of bird, beast, and fish, and the question still presents itself whether a development of one into the other is possible or probable. It seems to me at least probable that a Creator made the type, *e.g.*, Felis, and subsequent causes tended to give it the form of Leo or of the domestic cat.

**Pre-Adamite.**

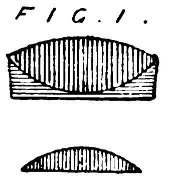
[24258.]—If it is not entering upon a forbidden subject, there is a statement in letter 24230 which seems to call for remark. It is, "On the whole, it seems more reasonable to believe that rudimentary structures are structures which were useful to the animal's ancestor." That this is true in some instances may be looked upon as certain; but is it not too much to infer, in the present state of science, that it always is so? May not a rudimentary structure be, not a remnant of a past structure which was once useful, but the germ of a structure which may become useful in time to come? That seals and whales, as mentioned in the above letter, are, like other animals, in a state of transition, may be granted; but in which direction are they moving? Do seals, for instance, tend to become entirely aquatic in their habits, so as to become something like porpoises, or do the latter tend first to partially and then to entirely terrestrial habits? To be able to answer this for certain, we ought to be able, to some extent, to trace the pedigree of the seal, in the same way that that of the horse has been done; it may in this case be traced distinctly to a four-toed animal about the size of a fox, the hipparion I believe it is called. The writer of the next letter (24231) tells us that "Evolution says that fish were the ancestors of mammals." If this be so, the change is from aquatic to terrestrial life, and not from terrestrial to aquatic, as the first letter supposes it to be—at least, in the cases of seals and whales.

**W. G. P.**

### THE MICRO-OBJECTIVE.—II.

[24259.]—Suppose a plano-convex lens to be used in connection with an over-corrected back, also plano-convex, we should have an arrangement like this (Fig. 1), in which there are six surfaces to prepare and three different curves, the optical result being no better—as regards the curve and colour errors—than may be obtained from a single pair, if properly constructed.

FIG. 1.



The difficulty about the proper construction of these lenses lies in the largeness of the angle required in micro-o.g.'s as compared with telescope o.g.'s. In these latter only about 9° of the circle or sphere is used, whilst in the former for a low power—say, 1in.—one would like at least 40°, for that would give only 20° of "aperture" in a plano.

If appropriate lenses be placed behind a plano-convex having, say, 40° of the sphere, its focus may be made to coincide with the centre of curvature, and thus its "aperture" would be equal to its angular dimensions, provided the back additions could transmit to the eye all the rays delivered by the front.

As objectives of 40° "angular aperture" and upwards need a combination of three lenses, our subject divides itself now into o.g.'s of two and o.g.'s of three lenses, or combinations of less or more than 40° "angular aperture." We will, however, call them high and low powers.

A good low power cannot be produced by the formula generally used for the high powers; a high power cannot be made at all as low powers are produced.

The lenses for an inch o.g. may be two plano's having foci as 1 : 2, both achromatic, and made of a plano-concave flint lens and double convex crown; curves of front to be of $\frac{3}{8}$in. radius, of back $\frac{5}{8}$in. radius; the distance between them is better decided by experiment, as it will not need to be equal to half the sum of their foci. This is our modification of Fig. 1 for a low power o.g., giving two extra surfaces, but only two curves instead of three; moreover, the combination is separable to form a 2in. single o.g. of passable quality.

Before saying anything further on the theoretical part of the subject, I will proceed with the practical—get a few lenses completed for o.g.'s and eyepieces, after which—if our Editor doesn't put on the extinguisher—I will describe the high powers, give curves and qualities of glass used in some of the best $\frac{1}{8}$ and 1-10in. powers that have been made by our experts, as well as those more simple data by which I have succeeded well with powers up to $\frac{1}{8}$in.

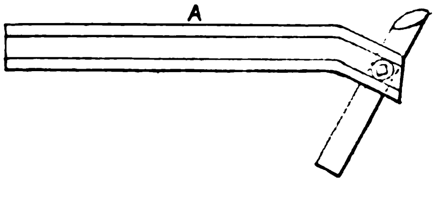
Whilst I am preparing the next paper, those who may be following me should prepare themselves with a bit of flint glass (see Sixpenny Sale Column), also a bit of the whitest patent plate (look through edge for colour); two or three ounces of emery powder like that on No. 1 cloth, a bit of flour emery, an ounce or two of rouge, some good clean hard pitch, and two or three of the best watchmaker's gravers (square) with which I turn up my concaves.

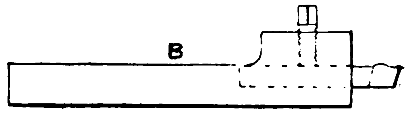
**Rob. Crus.**

### LATHE MATTERS.

[24260.]—There seems to be some doubt about the possibility of cutting a V-thread on a cylinder with a revolving cutter. To me it seems plain enough that it can be done, for given any V-thread it is certainly possible to turn a disc, the edge of which shall touch the thread in every part, and if that disc is of steel and teeth are cut in it, it will cut the same thread; but I think it will be a difficult tool to use. It must be set at exactly the line of centres, or it will make a lop-sided thread. This is easily seen by taking an extreme case and putting the cutter quite at the top or bottom of the work, when the distortion will be largest, and it must be also set at exactly the right angle or it will take too much out, a small error in the setting making much more difference than a similar one would in a point tool.

It may interest some readers to know of a very simple, easily made, and extremely useful tool holder. I have two in use, and find them handier and cheaper than ordinary forged tools, and they will stand any amount of hard use. That marked A is a piece of octagon steel, bent as shown and drilled to take $\frac{3}{8}$in. round tool steel, which is held in place by a set screw. This I use for plain work, and it is surprising what a heavy cut it will take with little expenditure of power, and power is a consideration when working a foot lathe. That marked B is a simple forging with $\frac{3}{8}$in. hole drilled horizontally, in which fit the $\frac{3}{8}$in. round tool. This I use for screw-cutting or parting tools or for ordinary tools for light cuts, but is most useful for the two former. If a tool breaks (and parting tools will do so at times), all there is to do is to file up to shape again, and that does not take long on $\frac{3}{8}$in. round. I suppose most of the readers of "Ours" can easily make these for themselves, and am sure will be pleased with them; but for any who have not convenience, and would like to try them, I will advertise in next week's "Sale" column.





**S. Beeching.**

[24261.]—I send a couple of sketches to indicate how a change of cutters becomes necessary for each different number of threads in a screw. Fig. 1 shows six threads of an 8-threaded screw of 1in. distance of threads, and also 1in. depth of threads, making the angle of thread 53° 6′ or thereabouts. The angle A B E is the angle of rise of top of thread which, with a diameter of 5·28in. and rise of 8in., is equal to 25° 45′ more or less. A C F is the angle about halfway down the thread, and is drawn about 31° 36′ A D G is the angle of rise of the bottom of the thread, which, with diameter of 3 28in. and 8in. rise, gives 37° 50′ A cutter is represented as placed in the groove at the mean angle of 31° 36′ with the line A D. The cutter fills the groove at top, and its thickness by measurement cannot be more than about ·85in. I find also by measurement on a wooden model, carefully lined out in the lathe, that a four-threaded screw would take a cutter about ·92in. thick, whilst, of course, a single-threaded screw would allow of one of very nearly 1in. thick being applied.

Fig. 2 shows a cutter ·90in. thick inclined to the path *a b* at the same angle as the difference between A C F and A D G, or 6° 14′, and it will be observed that it is making a groove 1in. wide at top, and that at $\frac{9}{10}$in. of its depth the groove which, if cut by a screw tool, would measure $\frac{1}{10}$in. wide, is here as nearly as possible $\frac{2}{10}$in. wide.

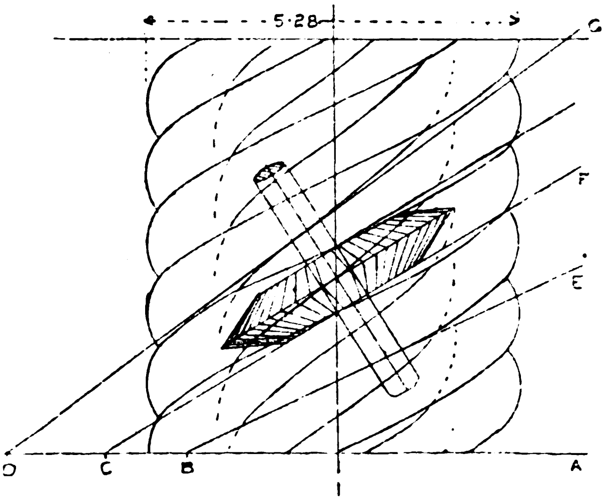


FIG. 1

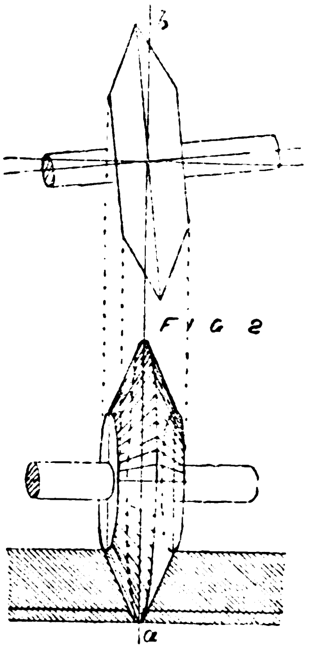

FIG 2

The plain answer to the plain question, "How is it?" &c., on p. 189 is, that metal headstocks taking the place of wooden ones, and the introduction of slide-rests, say 100 years ago, rendered imperative the adoption of a plain sliding fit in place of screws inaccurately cut, with insufficient length of bearing, and which, when somewhat worn, were always thrown further off the centre line by the very means used for steadying them.

As to letter 24239, calling my attention to the above question, I may remark that I do not answer questions to order, nor permit anyone to determine whether I may write, nor to choose or veto any subject for me; I can do all that for myself.

The paragraph one-third down, 3rd col., p. 214, appears to me a pure self-contradiction. The so-called cylinders are simply slides—one with a very short amount of traverse, and the other with a great deal more. As they are merely slides, they only require to be parallel; their cross section may be circular, and usually is so, until either a groove is cut or a flat filed on the one for the movable headstock, when it ceases to be a cylinder. It might very appropriately be of square or hexagon section, particularly if the lathe chucks screw on to or into it, as is sometimes done. I have one arranged so as to take the chucks.

As to the short one at rear end of mandrel, I should say economy, if nothing else, would indicate a plain fit as preferable to a screw. The hole has to be bored in either case, and fitting a plain plug with a pair of counter-nuts would certainly cost less than a screw, plus some means of setting it fast. I am quite ready to agree with "Vulcan" (see p. 236) that a cutter of, say, 55° can be used on any cylinder to cut any particular number of threads required; but that is a very different thing from saying that the resulting thread will be of the same angle, whether single, double, or of any other number of threads on some other diameter. No doubt a set of cutters might be made and used and a record kept if it were worth while; but in this respect they would be like toothed-wheel cutting tools—viz., a set for each gauge, and different tools for different numbers of threads, and, worst of all, very different cutters for such low numbers of threads as are ever used for screws.

An experiment recently made surprised me as regards the slightness of the distortion in cutting a moderately high-pitched screw with a cutter, and I may as well acknowledge the fact here as anywhere. It is quite impossible for me to pursue the subject for some time to come, and I write this hurriedly for the 22nd inst. **J. K. P.**

## CUTTING SCREW-THREADS WITH A REVOLVING CUTTER.

[24262.]—IT may be of interest to mention three cases in which the above plan is used. The first instance I found in an article on screw-cutting in the *Scientific American*, wherein the method was said to be the invention of Mr. Harton, and to be used by him in his well-known jaw chucks.

Joshua Rose also, in a book which, I believe, first appeared in the *Scientific American*, states that the Morse Company use it in making their taps. Lastly, there is Col. Dumbleton's screw-chaser, which has been described and favourably commented on in these columns.

Leaving the question of the trustworthiness of these instances to more practical men, I may refer to several advantages which the method appears to me to possess: Firstly, since the speed of the cut is wholly independent of that of the cutting-edge, the work will be better done—especially on soft material; it may proceed with the greatest deliberation and care, and may be stopped at a given point with the utmost exactitude. Secondly, the thread may be cut to its full depth at one trip; and thirdly, since the strain of the cut is not borne by the slide-rest, the possessor of a light or ornamental lathe is enabled to perform screw-cutting which he would not venture upon with a fixed tool.

"J. K. P.'s" sketches on p. 237 do not go far enough. The cutter in Fig. 2 may be compared to a vessel under sail, and "fetching where she points," while in Fig. 3 she is drifting bodily to leeward. There should have been a fourth Fig., showing that, when sail is made (or, in other words, when the change wheels are put into gear) on Fig. 3, the cutter (vessel or tool) will again travel in the line of her keel, and, as in Fig. 2, produce a symmetrical groove.

May 18. **Faber.**

## CUTTING SCREW-THREADS.

[24263.]—SEVERAL valuable letters have been given to us in our number for May 15. We are all anxious not to occupy valuable space in mere verbal disputation, yet some of us seem to be writing about one thing, and some about another.

Will "Vulcan" kindly reconsider his diagram and his terminology? Unless we start with clear and distinctive terms for the things about which we are writing, we are sure to get into confusion. "Vulcan's" diagram of a double-threaded screw (p. 236, col. 2) seems to me to show a cutter with its axis set at a horizontal angle to the lathe-axis. This is not what I have proposed. A revolving cutter, with its axis trimmed in the plane of the lathe-axis, becomes a bevel wheel; this is a frustum of a cone, and, at a certain angle, the side of this cone runs parallel to the lathe-axis. If the cutter-axis be trimmed additionally in a plane parallel to the plane of the lathe-axis, the cutter becomes a skew bevel wheel, and hyperboloidal surfaces come into the question. I will not now ask whether a rectangular helixoid—*i.e.*, a square-thread screw—surface could be ground up by a skew bevel wheel, as the object of this letter is merely to get accurate definition of the topics which crop up.

"Hadah" sends a clear letter and "Canmore's" diagram, Fig. 2 (p. 236, col. 2), perfectly shows what it is that I have proposed. I merely add that his line A B is my hypothenusal line, which, under the influence of the traverse, is transformed into *the helix*; and that his cutter-axis, C D, represents the line which, under the influence of the revolution, is transformed into *the normal helix*. In "Canmore's" text (par. 2) he gives a description of his diagram which, till we come to the bracket, I also adopt; but to his concluding sentence about the shape of the section I demur altogether. "Canmore's" conclusion does not seem to follow from his premises, and his Fig. 3 does not seem to represent the normal section which he refers to. I say that *there is no difference in the traverse cut of an angular point tool, whether fixed or revolving, so long as the tool clears itself*. In order that the tool clear itself, its plane of revolution must be tilted to the hypothenusal line which determines the rake of the thread. The thread surfaces also must be skew helixoids having a certain lateral angle, this angle being dependent upon conditions to which I have already referred (page 190, No. 1,049). If the revolving cutter be not accurately tilted to the hypothenusal line it cannot clear itself, and it cuts a groove more or less U-shaped, the sides of the thread being therefore left hollow. The square-thread screw-surfaces are rectangular helixoids; and the revolving square-tool, if used with these, would leave a U-shaped deformation of the groove. With other threads—those which are rounded or angular—the clearance is simply a question of more or less lateral curvature or lateral angle. Perhaps those readers to whom I have failed to make this clear will reperuse "Hadah's" letter at page 235.

The shapes assumed by the surface of a lady's fan as it is opened out or closed up will bring home to the eye the surface termed *a rectangular helixoid*. Upon a square screw-thread there are two such surfaces, one right-handed the other left-handed. If there must be, theoretically, deformation of the straight generating lines which determine the section of the angular thread, the sides of the groove would be rounded instead of hollowed, as in "Canmore's" figure. They would, in fact, be side arcs of an ellipse so flat as to be indistinguishable from straight lines.

Two of my old failures in the way of model screw-noses that I had at hand I have posted to "Vulcan," and have asked him to report upon their screw-threads. They were cut with a revolving point tool.

Perhaps "Canmore" will reconsider his Fig. 3, and the conclusion which I have ventured to demur to. Something more on the defects inherent in chasers would also be acceptable. There is no subject of greater interest or importance to the readers of the ENGLISH MECHANIC than that of "cutting screw-threads."

As to nomenclature—the following is what I understand by some of the terms. *Screw* is used in the ironmonger's sense. A *screw-thread* is not "a screw," but the thread or helicoidal projection upon the stem of the screw. A *screw-groove* is neither a screw-thread nor a screw. If, then, we use the terms screw or screw-bolt, screw-blank or cylinder, screw-stem, screw-thread or thread, and screw-groove or groove, when we respectively mean these things, we shall in future have no such corrections as recent letters have needed. By "stereotomy" of screw-threads I mean the sectioning of screw-threads and screw-grooves in various directions, and the describing of those sections. By "stereometry" of screw-threads I mean the measurement of the angles, sectional areas, and solid contents of the grooves and threads produced by tools ground to various forms and then tilted, rotated, or skewed at various angles to the traverse line.

*Reversible thread* means a thread of such shape that the nut or counterpart screw will go on equally well each way.

A *symmetrical* thread is the same thing as a "reversible" thread, but named from a different standpoint. "Vulcan" defines a "reversible" thread as having "its axial section bisected throughout by a radius cutting its apex on the centre of its summit." I should have defined it as "bisected throughout by the rectangular helixoid."

*Counter-screw* means sometimes the nut, and sometimes the bolt, according to which is the counterpart. There will also be *counter-thread* and *counter-groove*. The counter-screw may or may not have the same axial section as the screw. Screws for wood take a wooden counter-thread much larger than the iron thread to which it is opposed. But the thread surfaces should match, and counter-threads, though unlike each other, may be reversible. The propensity for word-coining must be restrained; but as the mind discriminates, so must the pen, if our notions are to be discussed without confusion.

*Abnormal* seems a confusing term when applied to screw-threads, as we must use the term *normal* in other senses.

The cut given by the cutting face of a tool when handled in various ways is a complicated and difficult subject by equation-mongering, but is simple enough when studied experimentally. If through an opening in a window shutter sunlight be let in, and a penny-piece be held so as to throw its shadow upon a screen placed at right angles to the path of the rays, we can realise all the changes of form in the cut by means of this simple projection apparatus. When the penny is held at right angles to the rays, it casts a circular shadow the size of the penny. If held parallel to the rays, it casts a straight line shadow as broad as the penny is thick, and as long as the diameter of the penny. If the penny be tilted, one diameter is shortened, and the shadow becomes an ellipse—*plus* the projection form of the thickness of the rim of the penny—the minor axis always being the cosine of the tilt.

But there is no manipulation by which both diameters of the shadow can be shortened or its thickness lessened. The penny cannot be made to cast the shadow of a farthing, nor can it be made to cast a shadow larger, or thicker, or longer in diameter than the penny. If, however, the screen be tilted, we can lengthen out either diameter of the shadow to any extent and without diminishing the other diameter.

In the first case the projection gives elliptic sections of the cylinder by diminution of one axis of the circle, and the short axis is the cosine of the tilt; in the other by the increase of one axis, and the lengthened axis is the secant of the tilt. The straight line shadow is, in one case, always the same length; in the other it may be lengthened out infinitely.

If, now, the penny be replaced by a revolving cutter attached to the tool carriage of a planer, and upon the planer bed beneath there be a slab of wood, we have only to lower the revolving cutter in order to make a cut into the slab. One way this cut will be a segment of the circle described by the revolving cutter, when projected along the line of its axis, and the other way a profile of the cutter when projected at right angles to its axis. The depth of the segmental cut will represent the depth to which the revolving cutter has been lowered. Now the shadow thrown by the revolving cutter is a cylinder whose section is the figure upon the screen—i.e., the projection-form of the tilted or untilted circle, *plus* the projection-form of the cutting-edge of the tool. By now putting the planer-bed in slow motion parallel to the line of projection, *the intercept* of the projection-form of the revolving cutter becomes the normal section of that segment of this cylinder-space which appears as the traverse-cut. If the cutter-axis be parallel to the traverse-line, the normal section of the traverse-cut will be a segment of a circular cylinder. If the cutter-axis be at an angle with the traverse-line, the normal section will be that of an elliptic cylinder whose short axis is on the line of tilt. The long axis of the elliptic section will always be the diameter of the revolving cutter, and the short axis will always be the cosine of the angle through which the plane of rotation has been tilted. It will be recollected that the thickness of the rim of the penny added its projection-outline to that of the tilted circle. Now, when the cutter-axis is parallel to the traverse-line, the profile of the cutter-face is of no account; but in all other cases the projection-form of its profile has to be interposed between two arcs of the elliptic curve derived from the projection-form of the circle. With small cuts, such as those used in shaping screw-threads and in most ornamental work, the projection-form of the cutting edge of the tool constitutes a very large factor in the resulting shape, and an endless variety of beautiful forms may be produced by varying the profile of the cutting edge and its relation to the traverse-line.

The second primary element to which I briefly referred at page 190 is exemplified by tilting *the screen* on which the projection-form of the object is received. Here, there comes into action a new set of variations, which, for the purpose of geometrical analysis, must be looked at apart from those due to the tilting of the revolving-cutter-plane. This tilting of the screen does not alter the form of the cylinder of shadow which is projected; it only varies the direction in which the shadow is cut, and in that way alters the form of the section. By appropriate chucking of the slab upon the planer bed these effects may all be superimposed upon those produced by rotating or tilting the cutter axis. If a cross motion of the cutter-frame along the tool slide be combined with the rectangular movement of the planer-bed—the cutter-plane being rotated to the hypothenusal line—all the phenomena of screw-cutting can be studied upon the flat, as I have already indicated (page 190). And one component after another can be put into the resultant. On rotating the cutter-plane at various angles athwart its traverse-line we see the external ellipse gradually substituted for the profile of the traverse-cut.

In cutting screw-grooves upon cylinders we bring in our third factor, i.e., *the helicoidal character*. Each particular screw-thread is an untransformable geometric entity, just as is the sphere of each particular radius. One screw-thread can no more be transformed into any other than a spherical surface of one radius can be transformed into a spherical surface of any other radius or into a plane. So long as this remains, so long will the screw-thread retain its helicoidity. The fact that the pitch of every screw-thread increases towards infinity at the axis makes it not possible for any one hypothenusal line to meet simultaneously the rake of concentric portions of screw-thread; but in equal step with the increase of curvature and the advance of helicoidity there comes an alteration in the outline of "the intercept" of the projection-form of the revolving cutter. In substituting the cylinder for the flat slab we have, in fact, *tilted our screen*. The flat slab intercepted a straight-line segment of the projection-form; the cylinder intercepts only a circular segment, and its intercept, therefore, does not rise so high up the shoulders of the cutter-circle. As the helicoidity and the curvature increase, so does the intercept shorten and fall away from the path of that portion of the cutter-circle which is shaping the groove. Therefore, the question is one of degree. To cut a screw-thread which approaches the last limits of theoretical accuracy is impracticable. With a fixed screw-tool the spiral base may be made a true counterpart of the thread; but it is only the edge of its cross-section which can cut. If the spiral base were to fit the screw as a true counterpart, there would be no relief, and the edges of the section would fail to cut. The question is, Which tool will true up a hardened steel screw most perfectly to the end of its thread?

Reverting to the projection-form given by the penny in parallel light as the guide for the stereometry of our cut, we must give further consideration to the influence of cutting-edge upon the projection-form. If the cutting sides meet at an angle of 50°, and we take the extreme case of a double-coned spindle-shaped revolving cutter-wheel, we settle the case out of which this discussion arose, and may also refer very briefly to the general proposition. Now, as the profile projection-form has an angle of 50°, it is obvious that this cutter can clear no cut whatever whose sides include an angle less than 50°. Here the cosine is 0, and, with every increment of cosine as the cutter-plane is rotated across the traverse-line, it is obvious that the edges of the projection circle will bulge out elliptically, and cut away the straight sides of the profile until they are obliterated by a U-shaped groove which, at the limit, becomes a segment of a circle. It is obvious that this obliteration will encroach more rapidly with the flat slab than with the revolving cylinder.

As I have before shown, *the normal helix* is the shortest line across a given number of thread-turns. Therefore, the section given by *the normal helixoid* is the section with the shortest base line. If also the radial altitude remain constant, it follows that the normal section will have the smallest angle, the shortest sides, and the least area, as well as the shortest base line. The narrowest part of the screw-groove must, therefore, be its *normal section*, and this is *the cut*. All other crossings must be wider, and if so, the tool will clear itself so long as the lateral angles of the sides are sufficient to allow clearance when the cutter-plane is tilted to the hypothenusal line which determines the rake of the thread. This tilt must be in a plane parallel to the lathe axis. **James Edmunds.**

Grafton-street, Bond-street, W.

## CRANK AXLES.

[24264.]—Your correspondent "Locomotive" (24238), page 235, is correct in stating that the crank axles break across the webs, through the fault of the fibre running in the wrong direction. If the present mode of forging crank axles is correct, why do they require hooping, which must enhance the price considerably, also the weight? There is a new mode of forging crank axles with the fibre running in the several directions as best suited to bear the various strains whilst in motion, patented by Messrs. Linney and Lawson, Rochdale-road, Manchester, in which they proposed to dispense with twisting to get the right angles; if so, it would certainly save the centre of the axle crystallising sooner than otherwise. **Wilfred.**

## THE MUSICAL SCALE.—WHAT IS A SEMITONE?

[24265.]—IN the scale of equal temperament a semitone is, of course, just the half of a whole-tone interval. In the harmonic scale it is greater than this, and in the natural or melodic scale it is less, the sharps in the former being below the flats, and in the latter above them. On the assumption that the harmonic scale is the only correct one, this relative position of the sharps and flats in the melodic scale has been pointed to as one of its errors. That it is by no means erroneous, however, may be shown by a simple musical test. There is a certain chromatic cadence, or phrase of four notes of frequent use in music, by means of which modulation is effected from any key into the key of the fourth of its scale. It is most generally used where a melody has modulated into the key of the fifth of that in which it began—to lead it back into the original key. Thus, a melody which began in the key of C, and has modulated into that of G, is restored to the key of C by the phrase consisting of the notes G, F sharp, F, and E. Of the intervals between these successive notes, only two (G—F sharp, and F—E) are true semitones; they belong respectively to the scales of G and C. The middle interval (F sharp—F) is not a semitone, and has no place in any scale. Whether it is more or less than a semitone may be determined by the following experiment:—Let a practised singer or violinist sing or play the cadence in question *without accompaniment*. It will be observed, and he will himself admit, that he makes the first and third intervals (the two semitones) narrower than the middle one. He does this naturally, and almost unavoidably, if he does his best to give the notes in tune. This arrangement of two semitones, separated by a perceptibly wider interval, of itself shows that the notes used by the performer are those of the melodic scale. If he had used those belonging to the harmonic scale the middle interval would have been the smallest of the three, and, moreover, the final note E would have sounded flat. But, indeed, unless aided by an accompaniment (necessarily harmonic), he would find it very difficult to give the phrase on these harmonic notes—impossible to do so *in tune*. It may here be noted that when the cadence in question is used for the purpose above described (in a harmonised piece), the first three notes are given *almost invariably* without accompaniment. The preceding chord having belonged to the key of G, the harmony is dropped until the E is reached, along with which it comes boldly in again with the "common chord" of C. The reason of this no doubt is that the cadence, being essentially melodic, cannot be given so effectively if harmonised. **W. Hardie.**

## PARAFFIN-OIL LAMPS.

[24266.]—I HAD no intention of troubling you again on this subject, but for J. Hughes's letter (24209, page 215). My greatest desire was to establish the fact that there was not the danger attached to paraffin lamps which might be inferred from what Sir F. Abel said, and what is generally considered to exist. I went through every letter that had been recently published in ours on this question up to my time of writing, and considered myself free to criticise any doubtful assertions, and to add, in return, what I could for the benefit of anyone, and cannot, therefore, consider J. Hughes's opening remarks in his last to be quite out of place and uncalled for.

Then, again, as to my championship of "paraffin oil," and that being the names of all hydrocarbons, is there no difference between the grass, the calf, the milk and the cow; or between ale, wine, or spirits?—is not paraffin oil considered the mildest of this class of hydrocarbons, and, as such, how was I wrong in recommending it in preference to those containing more serious qualities. Then, again, as to attempting to refute his argument, is not the "Silber" a domestic lamp?—and I touched upon this lamp because P. Ward says, in letter 24127, page 150, that his "Silber" had blown up several times. In reply to this, I gave my experience of the Silber lamp, all under most dangerous circumstances; as, for instance, some years since, before I fitted myself up with the lime-light, I worked three or four magic lanterns, with the Silber lamps. They were the best lanterns in the market, mahogany bodies tin lined. I have had the Silber lamp shut up in these, hours at a time, in full blaze, and the internal heat has been so great as to burn and dry up all the japan on the lantern tops, make the solder run, scorch the timber, and crack, at various times, three best 4½in. condensers. Yet with all this accumulated heat, and in such close quarters, my metal containers, too hot even to handle, never troubled me or gave way in the least. There is no English domestic lamp I should think ever burned under such severe conditions as these; where would a glass container have been under such conditions?

Then, again, J. Hughes says, "While combating his assertions, I go out of my way to prove him right, by admitting the advisability of using a cork washer," &c. Now, I deny this, and protest against his style of misconstruing my words to bolster up his own ideas. What I wrote was, "Even if there were positive danger in using metal containers, the interposition of a washer of cork between the burner and container would effectually prevent the heat from descending." How far this goes to prove his theory right, or to strengthen it in any way, I will leave others to judge. Then, again, he says, "All the replies (except Col. Shakespear's) have been particular and interesting, advocating, as they do, some special lamp or oil." How far Col. Shakespear has strengthened J. Hughes's theory respecting glass retainers I fail to see, nor has he answered a very simple question which that gentleman puts to him in his letter 24059, page 108; and, finally, is it right to say that all the other correspondents are advocating some special lamp or oil, and are interested? I am thinking there are many of "ours" who have read up J. Hughes's letters, who will think with me that his interests in glass, opal, or earthenware containers are very obvious, and, in fact, serious. Now, as to metal containers, I made reference to Martin's lamps in my last, and now quote a portion of their foot-notes, which is printed in something like italics at bottom of their circulars.

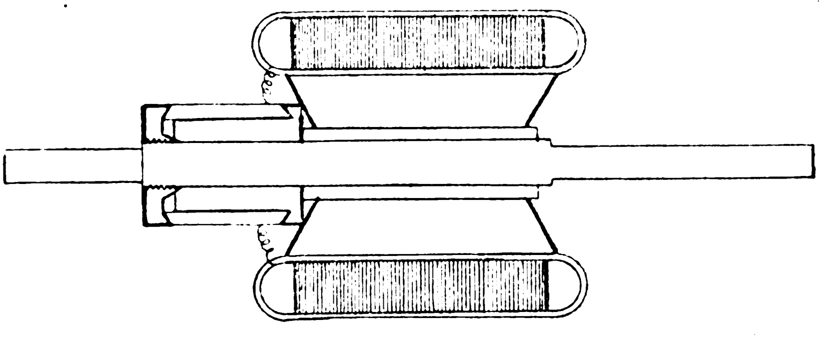
"The inventor is engaged in designing some new apparatus to be supplied with his burner, as well as new metallic lamps, &c." And lower down: "By the use of these lamps the public has the great advantage of security against fire, as they cannot be broken like those with glass or porcelain reservoirs."

And now as to my supposed interests in the lamp trade. I am not connected with it in any shape or form, nor with any other business particular; but I have well-to-do friends who live where gas does not reach them. Consequently, they rely entirely upon paraffin lamps for artificial light, and I may say they jump at every new thing in this line, in the hopes of reducing the annoyances and danger attending them. Having from time to time noticed these defects, I commenced two years back, to see if it was not possible to construct a lamp perfect in every degree. I have purchased every lamp I could get hold of with any pretensions to excellence, and have tested them in my laboratory in every conceivable way for light, heat, consumption, and attention required, and have spared no expense to establish the real facts of the merits and demerits of the various lamps, and have noted everything down most precisely; nor have I rested satisfied with one particular trial, but have made several under different conditions, and amongst my trials I have two or three lamps with metal containers, one more especially, that has never been out of use for 18 months, and it has been burning more than once from Monday morning until Saturday night, or continuously for 132 hours, giving an equal light all the time of about 22 c. p. This lamp I am willing to show to any one under certain conditions, or, what would be better, I will send a sketch, with many more important particulars, to "ours," if it is desirable, and the Editor is disposed to publish it. There is one important reason why metallic containers should gain the supremacy so long as they are safe in other respects; for we all know they are not so breakable as glass, &c., and that reason is that it would throw more work in our own factories for our own people, instead of importing such vast quantities of the glass and opal fittings as we do, and I was very pleased to see Mr. Martin's announcement as to metal lamps which are now to be seen, and there is not a doubt but they will be thoroughly appreciated.

**G. R. Postlethwaite.**

## 30-LIGHT DYNAMO.

[24267.]—Before commencing to describe the construction of this machine, I must mention that I address this letter to those who, having built small dynamos, are anxious to try their hands at a machine that will be something more than a mere toy. The first thing required is the shaft: this should be made of good mild steel, Bessemer steel answers admirably. The diameter of the shaft, when finished, must be 1½in., and its length 25in.; one end of shaft (commutator end) must now be turned down for 5in., to 1¼in. diameter; a thread 1¼in. long is now cut on shaft. On this thread is placed the disc which holds together the commutator bars (see sketch); 10in. from end of shaft a mark is placed, which shows the distance up to which the brass boss is driven; the other end of shaft is now turned down for a length 9in. to a diameter of 1¼in., leaving 11in. of shaft 1½in. diameter, on which is placed the boxwood drum which holds the commutator bars, and the brass centre-piece which supports the armature core.



We must now proceed to fix the sheet-iron rings which form the core of the armature. There are two methods which I know of: one is by means of a wooden boss, which is keyed on the shaft; the shaft is then put in the lathe, the wood turned slightly taper, and the armature driven gently on; a cement composed of pitch and guttapercha is poured between the armature and the wood, and so prevents the armature from slipping. The other method is to mount the armature on a star-shaped piece of brass, having four radial arms.

The first plan is simple, but it has several defects. 1st. Because it is a difficult matter to mount the ring true, as the slightest inequality in the winding will throw the ring out of truth, which is a serious fault in a high-speed dynamo. 2nd. The wires on the inside of the ring become hot, as the air cannot reach them to carry off the heat. 3rd. As the armature gets hot the cement gets soft, which, together with the expansion of the ring by the heat might cause an accident not pleasant to contemplate. There are some other objections to this method of mounting, but I think I have said enough to show that it is both unsatisfactory and unmechanical.

I shall, therefore, proceed to describe the second method. The arms of the brass boss must be made strong and substantial, and should taper from ½in. at their ends to 1¼in. where they join the boss, the length of the arms will be 8in. and the length of the boss 6in. I have endeavoured to make this plain in sketch, which shows a cross section of armature, commutator, and shaft. The next things we must consider are the sheet-iron rings, which form the core of the armature. These rings, which must be made of the best charcoal iron, are 7¾in. external diameter, 5in. internal diameter by $\frac{1}{20}$in. thick; thus the depth of the iron core will be 1⅜in. Before the rings are mounted they must be thoroughly annealed. I have experienced considerable difficulty in obtaining these rings, especially the larger sizes, and I am sure that anybody advertising them in the "E. M." at a reasonable price would meet with a ready sale.

The brass boss must now be keyed on shaft, care being taken to make a good job of it, as if ever the key shakes out or comes loose there will be a smash up. The shaft is now put in the lathe, and a few light cuts taken off the brass arms, till the rings slip on easily but not loosely.

The methods of fixing these rings on the brass arms are very varied, nearly every dynamo manufacturer having a different plan; so although I shall describe only one method, readers will understand that they are not tied down to any particular plan, but may use the one that seems to them the most practical and mechanical. The method I am about to describe is not very difficult, and I can answer for its practical value, as I have used it in the construction of machines of much larger dimensions than the one under consideration.

Two massive iron rings are to be forged, their dimensions being 8in. external diameter and 4⅜in. internal diameter by ¾in. thick. These rings are now put in the lathe and bored out, so that when heated they will just slip on the brass arms. On the outside face of one of the brass arms must be cut a slot 8in. long, ⅜in. broad, and ⅛in. deep, and in this slot is fitted a steel key, 8in. long by ⅜in. broad and ¼in. deep. The key will thus project ⅛in. above the brass. A slot is now cut in one of the heavy iron rings, which is then heated and slipped on the end of the brass arms. Before the ring has time to cool the shaft is put in the lathe, and a few taps given to the ring, so as to get it as near flat as possible, care being taken that the slot in ring is directly over the slot in the arm. When the ring is cold we may proceed to turn it up, a small key being put in to prevent any possibility of slip. The inside face of the ring is turned flat, and the outside face rounded, so as to prevent the wire when it is wound round being cut by the sharp edges. The small key may now be driven out, and the long 8in. key inserted. We must now proceed to mount and insulate the sheet-iron rings. I have tried several ways of insulating these rings, one of which was to give each ring two coats of thin Japan black; but although this method is easy, it does not give perfect insulation. A better plan, and the one I have generally used, is to insulate with rings of brown paper.

Before the iron rings are put on the arms, a notch is cut out on the inside of each ring, so as to allow the ring to slip over the long key. This key, it will be seen, prevents the possibility of the heavy rings or the sheet-iron rings from slipping, either while the armature is in motion or while the core is being trued up.

The rings are now slipped on the brass arms, a ring of brown paper being placed between each iron ring. We next slip on the second heavy ring, and clamp the whole together. This will be a somewhat difficult matter for an amateur who has not an engineer's shop at his disposal. The proper way to do it is to slot the heavy ring, and having heated it, slip it on the brass arms; then the core and shaft are placed in a specially constructed press, the whole of the rings forced firmly together and left to cool, when it is removed from the press; the heavy ring having shrunk on the brass arms holds the whole firmly together. Another method is to have the heavy iron ring bored out so that it slips on the brass arms cold; four or five U-shaped clamps are then used to draw the rings together. During this operation the armature is put in the lathe and occasionally turned round, when any unequal tightening of the clamps can be at once detected and remedied. When the rings are drawn together sufficiently tight, four small holes are drilled through the heavy ring into the brass arms; into these holes are driven tightly four small pins. The clamps may now be removed, and a light cut taken over the outside of the armature, so as to bring it up perfectly true; the outside of the second heavy ring is rounded off, and the armature is ready for the insulation and the wire. The core must now be insulated, which operation will require some care. I have found linen covered with Japan black very good for this purpose. The armature must be wound with the linen while the Japan black is wet. Four strips of linen, each 2in. by 5ft., will be sufficient. The wiring of the armature may now be proceeded with. The wire required will be 12lb. of No. 12 double c.c. so that the resistance of the armature will be ·07 ohm. on account of its stiffness. No. 12 will be difficult to wind, so it would be best to procure a stranded wire of equal proportions. The outside of armature must be entirely covered by a single layer of wire, while on the inside of the ring the wire must be wound two layers deep. We must now decide on the number of sections. Looking at the matter by the light of my own experience, I shall fix 24 as the proper number; but, of course, those who construct the dynamo may have as many more as they choose. After the armature is wound the layers should have several coats of good shellac varnish to keep out the damp; the armature must now be wound round with some fine steel wire to prevent the centrifugal force from disturbing the wire. Great care is necessary in winding on the steel wire that it does not cut through the insulation of the armature wires. The next to engage us will be the commutator, or, what is more correct, the collector, for there is no commutation of the induced current in the Gramme ring. The best metal for commutator bars is brass, which will be improved if it is well hammered. The best substance to insulate the commutator bars is vulcanised fibre, or, next to that, mica. The way the commutator bars are fixed is shown in sketch. The commutator should be 4in. in diameter and 4½in. long, the pulley may be 7in. in diameter by 5in. across face. I shall now conclude the description of armature. In my next letter I intend to describe F.M.'s, connections, winding, &c.

In letter 24107, Mr. Bottone describes a 30-lighter which has been put up by a friend of his, intimating at the same time that it might interest readers who were about to construct a dynamo of this size. Now, as some of "ours" might possibly start making a machine based on these particulars, I hope that Mr. Bottone and his friend will excuse me if I point out, among others, two serious defects in this machine. First, the resistance of the field-magnet is five times too large; second, that when the machine was running 30 lamps, the internal resistance was as large as the external, which means that of every horse-power transmitted to the pulley, half is wasted in the machine itself; so that the 2½ h.-p. engine which did not seem overtaxed, must have been indicating nearly 6 h.-p. I may add, that I doubt the ability of No. 14 wire to stand a continuous current of 30 ampères for four hours.

Coventry. **W. H. Eaves.**

## COMMUNICATION CORDS ON RAILWAYS.

[24268.]—Will any reader of your journal kindly give the law with regard to the use of communication cords on railways? On 24th April I was a passenger by the Midland from St. Pancras to Carlisle, and rode in a "bogie" carriage about the centre of train; near Luton I looked out of window on the right side and saw a quantity of brake-blocks, &c., lying on the step-board (doubtless left on by mistake). I should have pulled the cord and stopped the train, but feared I might be fined £5 if I did, as others have been; but it is a fearfully dangerous thing for platelayers on the road to have brake tackle left on the steps to fall off and strike men at a speed of 60 miles an hour. Can you, Sir, or will the Midland Company say, if under these dangerous circumstances, I should have been justified in pulling the cord?

**Carlisle Passenger.**

Carlisle, May 19.

## JERKS IN RAILWAY TRAINS.

[24269.]—In past numbers of the English Mechanic I have observed many letters on the action of brakes, and especially of those which leak off and cause jerks. Last week a Mr. Green was actually brought up before the magistrates for getting out of a train in motion, when in fact he had been thrown down by the leaking off and jerking of a brake. It seems, Sir, a very serious thing for passengers to be thrown down in this kind of fashion. Some years back I remember that an old and valued correspondent, "Meteor," used to give us details of jerks in trains. Would he kindly now explain the jerks which arise from running about twelve fish vans, not fitted with brakes, behind a train of carriages fitted with the Midland leak-off brake worked by vacuum?

I was on the platform, having got out before Mr. Green, witnessed the frightful jerk, saw the passenger thrown down and injured, and can swear that the train had just stopped and that it then moved again with a jerk; but don't just know in a scientific manner how to explain the cause of the jerk. So many passengers are being thrown down by this leaking-off jerking brake, that the matter is getting one of serious importance.

**One of the Passengers.**

New Humberstone, near Leicester, May 18.

# REPLIES TO QUERIES.

◆

**** In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[54825.]—**Salt, &c.** — I certainly agree with "F. W. H." that Nature's law is uniform, and that is why I begin with a civilised man instead of a so-called low type man, such as the Palæolithic men and their chipped flints. If these so-called implements were really manufactured by some primeval race of men, they ought to be found under varying conditions and in all localities. But in Europe they are always found in the river valleys, or associated in some way with the great floods of the Post-Glacial epoch, also with beds of sand, generally beneath such a deposit. They are always of flint, and washed away from the beds of chalk, which are found in the Somme Valley, at Hoxne, Bury St. Edmunds, Brandon, Herne Bay, Beaulness, Fimber, and at Fisherton, &c. The specimens are always picked and selected. No other implement or utensil has ever been found with these flints; every other trace has perished. Now, Mr. Sydney Skertchley, F.G.S., writing upon the "Antiquity of Man," says of Palæoliths (see ENGLISH MECHANIC for March 28, 1879, p. 49), that they "were more degraded than any known savage tribe," which I can well believe, if such men ever lived; but it is only as yet a supposition. Besides, if man had lived upon the earth for a thousand centuries (and that is not so long as some scientists insist upon), and starting from only a single pair, with the normal rate of increase, we should not be able to find a rood of ground without a skeleton in it. And instead of the caves and ancient sepulchres presenting a few doubtful Neanderthal skulls, the crania of Palæolithic men would have supplied inexhaustible stores of material for our manufacturers of bone manure. But coming to the cave men, we get something sure and firm to walk upon. Man is now upon the earth along with the remains of the mammals, as also of the goat, pig, sheep, rabbit, ox, bat, &c., in fact, all the modern animals. We have bone needles, awls, and gouges, potsherds, harpoons, ironstone weapons, and a very fine drawing of a hog-maned horse. Now, when men can produce hog; manes, and also make drawings of the same upon bone—said bone being cut with a saw, and the surface well polished—it won't do to speak of these men as being primitive. The artist, then, that drew this horse, lived at a time when horses' manes were cut to fashion; but Palæolithic times were by no means fashionable times either for men or horses.—DENS.

[55393.]—**To "Inviota."**—I should much like to have further details as to lathe-heads, &c., having the bed and standards fixed up and ready.—M.

[55875.] — **Cupola Blast.** — To "INVICTA."— You will find I sent a promised sketch, and it will be found on page 218. As to the steam used, I will endeavour shortly to lay some data before the readers of the "E.M." relative to the same cupola worked with a fan blast, and subsequently altered to run with a steam jet blast. On the subject of the ejector I may say that it is a very simple one. The idea being taken from a modification of the ejector in use with a vacuum-brake; but proportioned to deal with a large volume of heated gas instead of a small volume of air only. In the absence of the precise data I propose to bring forward, I may, in passing, say that originally we had a four h.p. boiler and engine. The engine is now dispensed with for blowing purposes, and the four h.p. nominal boiler certainly makes sufficient steam for two such ejectors as we have on the cupola. And as we, of course, have but one ejector, the moral is obvious. So far, the economy is in favour of the jet; whilst later on, we hope to utilise the waste gases for the production, in part, of the steam needed. The casing mentioned is now made into a feed-heater, and with a satisfactory result. In my reply on p. 218, several typographical errors have crept in, the chief one being in line 3, p. 219, which should read "fused," instead of "fired." The others are unimportant.—INVICTA.

[56209.]—**Sunshine Recorder.**—Many thanks to "Cyrax" for his reference to back numbers; but, as I am a new subscriber, and have no opportunity of referring to them, I should be glad if any one could give particulars of and directions for making the instrument, somewhat vaguely described in my query. I do not want one of the type having a glass focussing ball, but one in which the rays of the sun shine through a hole in the lid of a box of semicircular section, and trace a line on a strip of photographic paper on its curved bottom. Perhaps Mr. Lancaster could help me.— MIKROS.

[56282.]—**N.E. Locos. (U.Q.)**—A driver informs me that, owing to a deficiency of heating surface, McDonnell's engines would not steam well, and that they were too light to exert their calculated tractive force. I have never heard anyone say a kind word about them.—WM. JOHN GREY, F.C.S., Analytical Chemist, Newcastle-upon-Tyne.

[56312.] — **Distempering.** — Ellis Davidson's book on "House Painting," Lockwood and Co., is about the best for the purposes of your correspondent; but if he has access to back volumes, he will find a number of practical details which he cannot discover in any book. For instance, in Vol. XXXIX, pp. 497, 593, there is something about distemper. An improved distemper is described in Vol. XXXII. p. 79; Vol. XXXI. p. 144, contains a useful general description of the process.—NUN. DOR.

[56318.]—**Owls.**—I do not think "Agricola" will find any number of owls will much reduce the army of rats. They will eat mice, particularly field-mice; but rats are rather too large. The owls will not need any food to be supplied. All you have to do is to get them to take up their quarters with you, and then the less notice you take of them the better.—NUN. DOR.

[56322.]—**Miranda Pianista.**—I remember reading something about this in Vol. XXXVI. (see pp. 334, 431, 501, 547, 595); but as I have never seen it, cannot describe it. I see, however, that "pianistas" are entered at the International Inventions Exhibition; but whether the particular "Miranda" is there, this deponent knoweth not. As he means to go, he will eventually find out; but then the querist can also do that much better. As the querist seems to be aware that a company is being formed, I might suggest that the secretary would no doubt give all information.—N. E. CHILD.

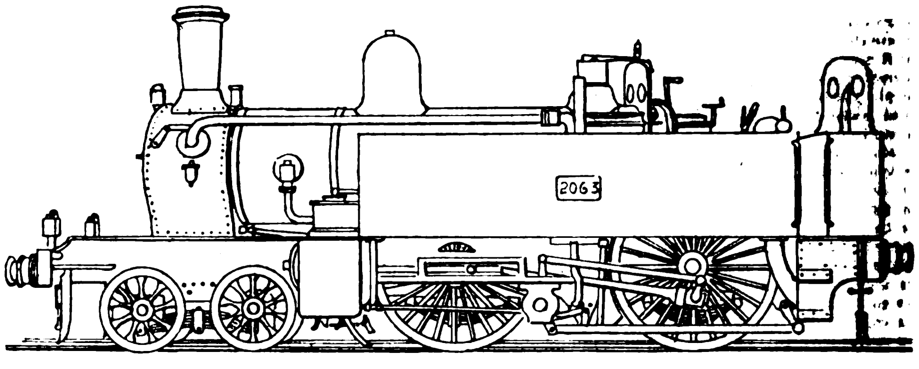
[56335.]—**Wheel Gearing.**—"J. H.'s" reply has greatly enlightened me, and I think I shall master my difficulty with a little more of his help and instructions on bevel-wheel work. I want to know if the inside lines should be the same distance as on the outside (pitch lines I mean), and what are the top and bottom lines for, and what distance should they be from the pitch line, and would "J. H." oblige me with the thickness of teeth from $\frac{1}{4}$in. to 4in. pitch? I know the length they should be—a third and a fourth; I think that is right.— MILLWRIGHT APPRENTICE.

[56351.]—**Worm in Mahogany.**—"G. S." should certainly not make up his wood without taking precautions to kill the worms. Fill every hole with oil; force it in, and finally stop up. No insect can live in a bath of oil.—N. E. CHILD.

[56354.]—**Turning Cannel Coal.**—I am afraid that not much can be done in the way of "turning" cannel coal; it may be filed into shape.—C. E. S. P.

[56354.]—**Turning Cannel Coal.**—"Ryhope" will find the method of turning Cannel coal described in Holtzapffel's "Turning and Mechanical Manipulation," Vol. I. page 162.—EN BON FOYE.

[56399.]—**L. and N.W. Compounds.** — The dimensions of the small or "Compound" class of these engines are: Two high-pressure cylinders, 13in. by 24in.; one low pressure cylinder 26in. by 24in. Boiler: length of barrel, 9ft. 10in.; mean diam., 4ft. 1$\frac{3}{16}$in. Firebox: length inside at top, 4ft. 9$\frac{5}{8}$in.; width, 3ft. 5$\frac{1}{4}$in.; length inside at bottom, 4ft. 10$\frac{1}{2}$in.; height 5ft. 5$\frac{3}{8}$in. Tubes: Number, 198; length between plates, 10ft. 1in.; diameter, 1$\frac{7}{8}$in. Heating surface: tubes, 980 sq. feet; firebox, 103·5 sq. feet—total, 1,083·5 sq. feet; grate area, 17ft. 1in. Wheels: leading, 3ft. 6in. diam.; front (radial) driving, 6ft. 6in. diam.; trail driving, 6ft. 6in. diam. Wheel base: leading to front driving wheel, 9ft. 4in.; Front driving to trailing driving wheel, 8ft. 3in.—Total base, 17ft. 7in. Weight: empty, 34tons 15cwt.; in working order, 37ft. 15ft. The large new ones of the "Dreadnought" class are of the following dimensions: Two high-pressure cylinders, 14in. by 24in.; one low-pressure cylinder 30in. by 24in. Boiler: length of barrel, 11ft.; diameter, 4ft. 3in. Firebox: length outside, 6ft. 10in.; depth below centre line of barrel, 6ft. 3$\frac{1}{2}$in. Tubes: number, 225; length between plates, 11ft. 3in.; diameter, 1$\frac{7}{8}$in. Heating surface: tubes, 1,242·4 sq. feet; firebox, 159·1—total, 1401·5. Grate area, 20ft. 5in. Wheels: leading (radial), 3ft. 9in. diam.; front driving, 6ft. 3in. diam.; trail driving, 6ft. 3in. diam. Wheel base: leading to front driving wheel, 8ft. 5in.; front driving to trailing driving wheel, 9ft. 8in—Total base, 18ft. 1in. Weight: empty, 39tons 10cwt.; in working order, 42tons 10cwt. In this new type the leading wheels are again in their usual position, and give the engine a neater appearance than when under the smoke-box, as in the previous type. Some time since there was a query about L. and N.W. bogies on the Metropolitan; one of these has now been compounded, and I send sketch of it herewith. The dimensions of these engines, which were bought from Beyer, Peacock, and Co., are—Non-compound: Cylinders, 17in. by 24in.; boiler, 10ft. 3in. by 4ft.; 164 tubes, 10ft. 6$\frac{3}{8}$in. long by 2in. diameter. Heating surface: tubes, 903 sq. ft.; firebox, 111 sq. ft.—total, 1,014 sq. ft. Grate area, 13ft. 1in. Diameter of coupled wheels, 5ft. 9in. Wheel base: c. of bogie to c. of driving, 9ft. 11in.; c. of driving to c. of trailing, 8ft. 10in.—total, 18ft. 9in. Weight, 45tons; pressure, 120lb. Dimensions of 2063, compounded: 2 high-pressure cylinders, 13in. by 24in.; one low-pressure cylinder, 26in. by 24in.; boiler barrel, 10ft. 6in. by 3ft. 10$\frac{1}{2}$in.; 177 tubes, 10ft. 9in. long by 1$\frac{3}{4}$in. diameter. Heating surface: tubes, 933·86 sq. ft.; firebox, 94·57 sq. ft. — total, 1,028 43 sq. ft. Grate area, 14ft. 6in. Wheel base: c. of bogie to c. of driving, 9ft. 4in.; c. of driving to c. of trailing driving, 8ft. 10in.—total, 18ft. 2in. Weight, 46tons 17cwt.; pressure, 150lb. Capacity of tanks, 1,250 gallons.—B.



[56355.]—**Legal.**—No. The "references were the property of the person to whom they are sent."— LIMB O' TH' LAW.

[56383.]—**The New Station at Birmingham.** —I cannot give you the information, as there are about six platforms whose combined length, that is, if each were placed end to end, would exceed a mile and a quarter. I wish to correct an error which occurred in my previous answer (page 177). I there said "there are seven through lines," which should have been "there are eleven through lines." —H. W. HUDSON.

[56427.]—**Gramme Armature.**—Would Mr. Bottone kindly add to the value of his sketch of small Gramme armature by giving us a sketch of F.M.'s best adapted to that shown in his drawing, with size and mode of winding, &c. Our warmest thanks are due to him for his lucid little sketch.— VIGILIA.

[56468.]—**Turning Cranks.**—"Young Smith" asks: "What kind of lathe is used for turning inide of crank up?"—the shafts being made of 1$\frac{1}{4}$in. round iron, 6in. throw, and 3ft 6in. long. Your correspondent says, rather confidently, that the method described in reply No. 56127 is not practicable in this case, as, owing to their length and small diameter, they would require some support in the middle. If "Young Smith" expects a job of this kind to be done without some amount of trouble, I fear he is greatly mistaken. There *are* machines for turning crank pins. In these machines the work is stationary, the *tool* being made to travel round the work. They are used only for turning the pins of large and, consequently, very heavy cranks, which, if turned in the lathe, would require an enormous weight on the chuck to counterbalance the weight of the shaft and quadrants. For reasons which I need not discuss, I do not think these machines could be adapted to turn such small cranks as those above referred to. There is no doubt that some contrivance to prevent the work springing away from the tool would be of immense service in turning cranks of small diameter. Perhaps the only appliance that could be used for this purpose would be something in the form of an eccentric and strap, which might be constructed in the manner indicated by the following figures:—Fig. 1 is a side view of a cast-iron sheave, and Fig. 2 an edge view of the same. The large slot Fig. 1 is for the reception of the block, Figs. 3 and 4. The two small slots, Figs. 1 and 2, are for the purpose of inserting bolts to secure the block to the sheave, after adjusting the block to the requisite degree of eccentricity in the sheave. The block is not unlike a gland. The principal difference is that it has two flats planed on it to fit the slot in the sheave, or it may be made square. It is bored to fit the shaft to be turned, and to which it may be secured by a key. The holes in the lugs of the block correspond, in distance apart, to the small slots in the sheave. The Figs. are not drawn to scale. The sheave may be run in a wood carrier, or in a brass or iron strap secured to the lathe frame. It will be seen that this contrivance can be used for cranks of different throw, and also by having blocks to suit, of different diameters. If intended to run in wood, it would be better not to continue the large slot right to the periphery of the sheave.—AN ENGLISH MECHANIC, Newcastle-on-Tyne.

FIG 1

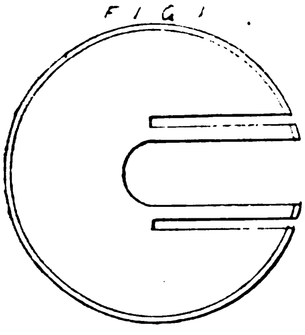


FIG 2

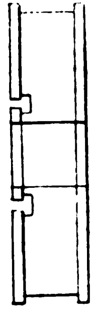

FIG 3.

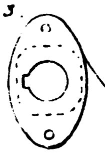

FIG 4

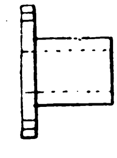


[56479.]—**Surface Condenser.**—Seeing that "C. E., jun.," in his reply to this question last week, has made one or two good-natured errors, I have worked out the subject from details to hand of one out of several well-proportioned compound marine engines with which I have had to deal, and with the Editor's permission I submit the following:—In the reckoning, after stating the total I.H.P. of the engines is 350, and in this case = 2·8 times the nominal power, we need deal only with the low-pressure cylinder: diameter = 55½in., stroke 32in., revols. per min. 65. The indicator diagram shows that at each revolution of the engines the low-pressure cylinder twice discharges its contents at an absolute pressure of 10lb. into the condenser; thus the condenser receives 5,785 cubic feet of steam per minute, equal to 153lb. weight, each unit having a total temperature of 1,172° F. The condensing water at 52° F., after circulating about the tubes, is discharged at 94° F., whilst the condensed steam, as feed water, is drawn off from the condenser at 130° F. Now, each unit of steam has to give up 1,172 – 130 = 1,042° F., and the available cold to do it with is 94 – 52 = 42° F. Then $\frac{1042 \times 153}{42}$ = 3,779lb. of condensing water required per minute, or 24·7lb. of water per minute to condense 1lb. of steam, having a temperature due to 10lb. absolute pressure per square inch. This gives some idea of the large quantity of condensing water required for a surface condenser, even when the steam is used very expansively in the cylinder. The modern practice is two to three square feet of tube surface per I.H.P., and never less than two square feet. In this condenser there was about 900 square feet, or 2·57 square feet of tube surface per I.H.P. I do not think there is any off-hand rule for finding the quantity of water required; but "Subscriber" will find no difficulty after fixing on the respective temperatures of the waters and steam to be condensed.—YAMA.

[56484.]—**Varnished Wallpaper.**—"C.D.R." is to be congratulated on his discovery of the detergent properties of soap-and-water; but it is regretable that he does not suggest the attainment of much honour as a critic. To endeavour to clean dirty, smoky wallpaper with a rag and paraffin oil is, it appears, "simply nonsense," and "Nun. Dor." is told (very properly, too) that he "should read queries before he attempts to reply." Now, I confess that when I read "Virago's" query, I thought that she had of course tried soap-and-water, probably also solution of soda or weak liquor of ammonia, and wanted something to remove greasy or sooty marks, stains left by flies, &c., and remembering how successful I was when trying paraffin oil and a rag, with, if I recollect, a little elbow grease, I just dotted down the reply which has produced a thoroughly courageous critic, who winds up with what I suppose is intended for a climax—"you might as well clean dirty windows with paraffin oil as dirty wallpaper." Well, if the windows are much begrimed with soot and grease, it is wonderful how very effective is a rag just moistened with paraffin oil. For cleaning paint or varnish I prefer to avoid soda or potash—even soap-and-water,—and if weak ammonia solution (I use the carbonate) does not remove the "dirt," a rub with a rag moistened with paraffin oil rarely fails.—NUN. DOR.

[56485.]—**Model Boat.**—To "VIRAGO."—I am glad my reply met the exigencies of your requirement. I do not at the moment recollect anything I can add to the information briefly given. But you will know where to apply if you want any further point elucidated.—INVICTA.

[56502.]—**Faulty Dynamo.**—To MR. BOTTONE.—The formula given for finding the proper resistance of the shunt-wound dynamo, if written in full, would stand: "The resistance of the field magnets' coils must be equal to the square of the resistance of the external circuit, divided by the resistance of the armature." That is S. P. Thompson's rule.—S. BOTTONE.

[56509.]—**Cheap Gas.**—To "INVICTA."—I much regret that the announcement named did not meet my eye, and hence the reason why I did not at once communicate. I therefore beg to publicly tender him my regrets for the oversight, and should any other brother reader be suffering from a similar neglect on my part, I would desire to tender him my sincere apologies in advance, and to assure both our friend Mr. Barry and any other gentleman that the oversight was entirely unintentional on my part. I also regret that, through absence from home, I did not see my copy of the "E. M." for the 8th until the date of the succeeding issue, and hence a further delay in dealing with the matter, which might otherwise appear as evidence of still further inattention on my part.—INVICTA.

[56519.]—**Chemical.**—When soap is placed in water it has an alkali thrown out, and an acid left free to combine with the fatty matter, &c., on the body or object being washed, and forms a soluble compound. When, however, the water is hard—that is, contains salts of calcium and magnesium—the metal combines with the fatty acid and forms an insoluble compound, producing what is known as curdling.—FABER FABRUM ADJUVET.

[56527.]—**Engine.**—To "INVICTA" OR "GLATTON."—I would with the greatest pleasure possible give you all the information you may need; but your dimensions are given in such a way that I think it best to ask you to put them in such a form that no mistake may creep in. I shall want to know (1) length and width of steam ports, (2) width of the bars between, (3) length and width of exhaust port. I assume that the steam port and bars are $\frac{3}{32}$in. wide respectively. Is this so? because, as will be seen, the dimensions may read otherwise. Now, as to some of the points you name, I may say that the engine in question would be rated by me as ¾ h.p. for each cylinder. With the speed and pressure you mention, it would indicate possibly 2 h.p. With only 60lb. steam you would need a screw of fine pitch to get 140 revolutions per minute. For such a pair of engines I should use a three-blade fan, 15in. diameter and 12in. pitch, width of blades would depend on many points; but if on a Griffiths model, I should make the middle of the blades 3in. wide. Then as to the boiler, that may be of the form illustrated at page 326 of last Vol.: Length, 3ft. 6in.; diameter of shell, 2ft. 6in.; furnace tube, 1ft. 3in. diameter and 3ft. 6in. long; return tubes thirty in number, 1½in. diameter and same length. A furnace tube, viz., 3ft. 6in. Such tubes will be sufficiently large in the bore to draw freely enough for the length, and will, with the fire-grate, which should be 1ft. 3in. long, give you ample steaming power; such a boiler for its size will give an exceedingly good account of a pair of engines run at the speed you name, always assuming the exhaust be sent into the funnel. Now had you consulted the contributors to the "E. M." earlier, I would have advised you on a different line altogether as far as your engine goes; and I would mention that my ideas of what a compact and really serviceable screw-launch should be may be seen at the Inventions Exhibition at South Kensington. I have above referred to the exhaust as being sent into the funnel to sharpen the draught. This is a necessary evil with the engines you have. The continued sharp "puff-puff" of the exhaust is to me always a sound that is unpleasant, and hence I always recommend a far superior system where the natural draught is sufficient and the noisy "puff" is abolished; therefore we get two advantages at once with extra power as well. If any of our mechanical friends are contemplating building the machinery for a steam launch I would recommend them earnestly to lay the matter before the contributors to this journal, and the appeal, I know, will not be in vain, and some ideas would be imparted which will be of value.—INVICTA.

[56533.]—**Pocket Telescope.**—You can increase the power, but at the expense of the light, which you say is at present not excessive. You cannot improve the definition, as that is a function of the o.g. Neither can you increase the magnifying power except at the expense of a loss of light. I may for myself say I do not know of any cheap expedient to effect your wishes other than the purchase of a larger o.g.—INVICTA.

[56539.]—**Electric Lighting.**—I was hoping that some abler correspondent would have replied in last week's "E. M." to your queries of a fortnight ago. No reply having appeared, I shall try in a humble way to give some of the desired information. 1. You say that in the sunk flat of your warehouse are large piles of paper which will interfere with the proper diffusion of the light. This settles the question as to the system of electric lighting. Incandescent lamps would be of greater advantage than arc lamps, for this reason, that you will obtain a better distribution of the light, by being able to place a lamp wherever it is wanted, instead of having an intense light at a given point, gradually fading into darkness. 2. Assuming the standard burner to yield an illumination equal to 16 candles, your 12 gas jets will give a light of 192 candles. To come to plainer figures, your warehouse would require a light of 200 candle-power, and to produce this 10 lamps of 20 candle-power each would be required. 3. On the incandescent system one horse-power is necessary to yield 200 c.p. effectively. 4. The cost of a 200 c.p. dynamo and wires may be put down roughly at £30. The lamps would cost about 5s. each, and as their usual life is not much more than 1,000 hours, the cost of 10 would be 3d. per hour. Taking the cost of dynamo as stated, let us allow 4d. per hour for interest and repairs both on the dynamo and the gas-engine, and 2d. per hour for oil, sundries, and attendance; the total cost would stand, roughly, thus:—

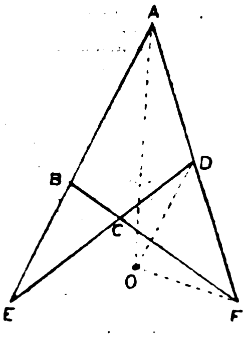
| | | |
|---|---|---|
| Gas for motive power...... | 4d. | per hour |
| Lamps .................... | 3d. | ,, ,, |
| Interest and repairs ...... | 4d. | ,, ,, |
| Sundries and attendance .. | 2d. | ,, ,, |
| 200 c.p. total cost .... | 13d. | ,, ,, |

An arc light of the same power, though very much cheaper, might not be so effective; but an efficient and economical light might be got by adopting a combination of the two systems. The most suitable arrangement, however, would depend on the nature of the operations carried on.—BOBADIL.

[56546.]—**Magnetic Moment.**—The answer to this question should be 30, and not 300, as given. Magnetic moment is the length of the magnet multiplied by the strength of its poles; and as the magnet was 10 c.m. long and 3 units in strength, the product is 30. The intensity of the field does not enter into the question of magnetic moment.—WM. JOHN GREY, F.C.S., Analytical Chemist, Newcastle-upon-Tyne.

[56547.]—**Geometrical.**—"J. C." has now two views of Todhunter's "Exercise" before him. From whichever point it be looked at, it will be seen that the exercise is little less than a cram. "J. C." may fairly object to L. Edmond's statement, since the least number of lines required to form the four triangles (exclusive of overlapping ones) amount to nine. For my part, I do not think Todhunter had Miquel's theorem in view at all when he wrote exercise 570; but be that as it may, if "J. C." turns to p. 80, "The Common Sense of the Exact Sciences," by Prof. Clifford (International Scientific Series), he may be enabled to form his own opinion on the matter.—EX-BLACKSMITH, Gorton Brook.

[56547.] — **Geometrical.** — Todhunter is quite right. Four straight lines in a plane form what is called a "Complete Quadrilateral," in which there are four triangles. Thus, in the figure, A E D, A F B, E B C, F C D are the four triangles. The proof is immediate. Let O be the other common point of the circles round A E D and A F B; then since the points O F A B are concyclic, the angle O F B = the angle O A B. Again, because the

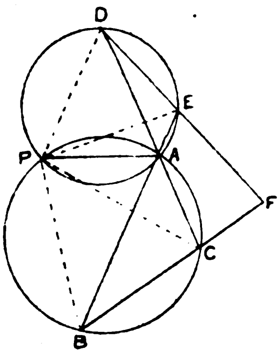


points O E A D are concyclic, the angle O A B = the angle O D C.

∴ the angle O F B = the angle O D C;
∴ the points O F D C are concyclic.

Or O is on the circle round F C D; similarly it is on the circle round E B C.—Hemisus.

[56547.]—**Geometrical.**—I cannot understand "J. C.'s" difficulty. There appears to be no mistake. Let AB, BC, CD, DE be the four straight lines, forming the four triangles ABC, ADE, BEF, DCF. Let the circles circumscribing ABC, DAE, intersect in P; join PD, PE, PA, PB. Then ∠ APD = suppt. of ∠ AED = ∠ AEF; also ∠ APC = ∠ ABF



∴ ∠ DPC = ∠ BEF + ∠ EBF = suppt. of DFC ∴ the circle circumscribing △ DFC passed through P. Also ∠ APB = ∠ ACF and ∠ APE = ∠ ADF ∴ ∠ EPB = ACF + ∠ CDF = suppt. of ∠ EFB. ∴ the circle circumscribing △ EBF passes through P. Hence the four circumscribing circles passes through one point. *Q.E.D.*—T. H. L.

[56547.]—**Geometry.**—If "J. C." will refer to the 5th prop. of Euclid, he will find his difficulty explained by the fig. of the Pons Asinorum. Leaving out the base B C in the figure, we have the four lines A F, A G, B C, C F, the two last intersecting in a point H, say. Then the four triangles are A B G, A C F, B H F, C H G. Circles circumscribing these triangles all pass through one point, as "J. C." will find if he is clever at describing intersecting circles with accuracy.—L. S.

[56547.]—**Geometrical** — Many thanks to L. Edmunds and "Ex-Blacksmith" for their endeavours to help me; but I must point out that L. Edmunds's triangles require 12 straight lines of 4 lengths for their formation; or, if some of the sides are made to do double duty, 9, or at least 8. If the lines were all equal, according to L. Edmunds, we could make 4 triangles with only one straight line. I also will point out to "Ex-Blacksmith" that in the question Todhunter does not state that the plane is 4 sides, or, indeed, that it is bounded in any way whatever, and that anyhow the triangles would not be formed by the 4 straight lines, but by them together with the supposed sides of the plane; thus, in all, making really 8 straight lines. I am afraid I have, at last, caught Todhunter tripping.—J. C.

[56547.]—**Geometrical.**—"J. C." will probably be surprised at the replies of Mr. L. Edmunds and "Ex-Blacksmith" to his query. The former coolly uses twelve lines, and because they happen to be equal in threes, thinks he has overcome the difficulty. The latter uses only eight lines, but he ascribes to Todhunter the absurdity of giving for an exercise a most watery repetition of a plain proposition. "J. C." will find a proposition more suitable to his taste in the following. Let *a b* and *a c* be two straight lines, meeting in the point *a*. In them take points *d* and *e* respectively. Join *b e* and *d c*, and let these lines cut in *f*. Prove that the circles circumscribing the triangles *a d c*, *a b e*, *d b f*, and *e f c*—all pass through a common point.—J. L. Dwyer.

[56553.]—**Gasoline for Gas-Engine.**—I will give you with pleasure the sizes you ask. Supposing the engine to be non-compressing, I should advise a 9in. cylinder and 14in. stroke. The tube you name would not, in my opinion, be suitable. I should require tube at least ½in. thick when bored, so that the tube you name would be too thin. Again, metal tube would be not anything so suitable as cast iron for such a job; and I think that, looking at the question all round, there would be so many difficulties with a built-up cylinder, that the first cost of a pattern and a cast-iron cylinder would be much the cheapest in the end. All engines on the lines of the Bischopp absolutely require a cast-iron cylinder, as no lubricant is used, and the high temperature of the exploding gases render a metal cylinder impracticable; otherwise it would be far easier to make it in metal rather than cast iron, if it were possible, which it is not. I am always happy to help you at any time.—Invicta.

[56557.]—**Coefficient of Centrifugal Force.**—I have not got the book that Mr. Wm. John Grey refers to, but I presume he requires to know from whence the coefficient ·000341 is derived. Now, if we examine the formula for centrifugal force, viz., $C = \frac{W v^2}{g R}$, we see that for revolving bodies connected with engine work, such as governor balls, flywheels, &c., where the revolutions per minute are known, we should first have to find the velocity in feet per second before we could apply the above formula, thus entailing two calculations instead of one. Let us work out the formula, and bring in revolutions per minute instead of velocity in feet per second.
